The inſipide taſte as I ſaid before, doth not argue any certaine effect or property to worke upon the ſtone or gravell either to diſſolve or expell it, unleſſe it be by ſome ſpecificall or hidden property therein, yet aſſuredly it could not in my opinion have received the name of a Saxifrage among ſo many authors without ſome proper effect therefore, which roſe no doubt from ſome Empyricall obſervation and practiſe, which gave it both the name and the opinion, unleſſe it might from the likeneſſe of the leaves as I ſaid before judged, which becauſe I cannot maintaine nor diſprove, I leave it for others to diſprove if they can.

CHAP. IV.

Saxifraga vera Dioſcoridis Matthioli. *Matthiolus* his true Saxifrage of *Dioſcorides*.

THe true Saxifrage of *Dioſcorides*, according to the judgement of *Matthiolus* and others, from whom he received it, is a ſmall low ſhrubby Plant, that ſendeth forth divers ſmall wooddy, and ſomewhat hairy ſtalkes, full of joynts cloſe ſet one unto another, having divers ſmall ſhort and whitiſh narrow leaves, growing divers together at every joynt, at the toppe whereof come forth very ſmall purpliſh white flowers, ſet with ſome leaves under them, this doth ſomewhat reſemble Time, both in the lowneſſe and manner of growing, but hath no ſuch ſweete ſent, or hot ſharpe taſte like unto it, whereby it may be knowne to be a different Plant.

Saxifraga vera Dioſcoridis Matthioli.
Matthiolus his true Saxifrage of *Dioſcorides*.

The Place.

It hath beene ſent unto us out of *Italy* among other rare ſeeds, but where the naturall place of growing is, it is not readily knowne.

The Time.

It is very ſlow in growing, ſo that it did not flower untill ſo late in the yeare, that an early froſt cauſed it to periſh, that we could gather no ſeede.

The Names.

It is very probable that it is the true Σαξίφραγον *Sarxiphragon* or *Saxifragon* of *Dioſcorides*, and differeth much from the *Satureia* or *Thymbra* St. *Iuliani* of *Pena* and *Lobel*, ſet forth before in this worke, which *Bauhinus* calleth *ſpicata*, (that it may the better agree with *Dioſcorides* his *Satureia*) and ſuppoſeth to be this plant of *Matthiolus*, but I by the ſight and taſte of the plant not finding it to agree, with the ſmell or taſte of either Time or Savory, cannot agree unto him, but doe rather judge it to be a peculiar plant of it ſelfe, and to come neerer unto his *Thymum inodorum* before mentioned, and therefore have ſeparated it from the other Saxifrages that follow *Dodonæus*: (and *Gerard* who hath but onely tranſlated his words) judgeth the *Serpyllum vulgare*, to be *Dioſcorides* his Saxifrage, but they are both deceived.

The Vertues.

I doe verily beleeve that this plant, hath either the ſame eſpeciall vertues againſt the ſtone and gravell, reſtraint of making water and other the qualities, whereunto *Dioſcorides* doth appropriate his Saxifrage, or commeth ſomewhat neere thereunto, and I am hereunto chiefly led by the ſight and forme of the plant, and from the name of *Saxifraga Dioſcoridis*, whereby it was ſent unto us.

CHAP. V.

1. *Saxifraga major Italorum Matthioli.* *Matthiolus* his *Italian* great Saxifrage.

THe great Saxifrage of the *Italians*, as *Matthiolus* relateth it, hath a great wooddy ſtemme of the bigneſſe of ones finger, toward the lower end, full of chinkes or clefts, ſpreading very thicke, with many ſlender hard whitiſh branches full of joynts, and two ſmall long whitiſh greene pointed leaves, ſet at every joynt very like unto Pinkes, and many other ſmaller and ſhorter ſtanding with them: the flowers ſtand at the toppes of the branches, out of whitiſh greene huskes, conſiſting of five

five and ſometimes ſixe, ſmall white leaves, endented at the ends, of a ſweete ſmell, ſtanding above the huskes, laid open like a little ſtarre, after which follow ſmall round and ſomewhat long heads, full of ſmall reddiſh round ſeede, much leſſe then that of Poppy. *Lobel* and *Pena* thinketh that this Saxifrage is the ſame that they have ſet forth in their *Adverſaria*, but that with us it groweth not ſo great and wooddy.

2. *Saxifraga Anglica Lobely Occidentalium.* *Lobels* Weſt Country Saxifrage.

This ſaith *Lobel* is very like the former, but that the flowers are white, and grow in ſmall tufts at the toppes of the ſmall ſtalkes, the whole plant being white.

2. *Saxifraga Anglica Occidentalium Lobelij.*
Lobels Weſt Country Saxifrage.

3. *Saxifraga paluſtris Anglicana.*
Mr. *Goodyers* Marſh Saxifrage.

4. *Saxifraga Cretica prior.*
The former of the two Saxifrages of *Candy.*

8. *Saxifraga Bavarica.*
The Saxifrage of *Bavaria.*

3. *Saxifraga paluſtris Anglica.* Mr. *Goodyers* Marſh Saxifrage.

This hath ſundry ſmall leaves about an inch long, very ſmall and narrow lying next the roote, among which riſe divers ſlender round ſtalkes about halfe a foote high, full of joynts and branched here and there, ſet at the joynts with the like ſmall leaves many together, but two for the moſt part longer then the reſt, growing ſmaller and ſhorter up to the toppes, where groweth one pretty large white flower, made of five round pointed leaves a peece, with ſome white chives in the mi dle, the roote is ſmall and fibrous.

4. *Saxifraga Cretica prior Alpino.* *Alpinus* his firſt *Candy* Saxifrage.

From a ſmall long white roote, having a few ſmall fibres at the head, ſhooteth forth a hard white wooddy ſtalke, divided into ſundry ſmall branches, ſub-divided alſo into other leſſer, which ſtand not upright but leane downewards, ſet at each joynt with two ſmall long and pointed leaves, ſomewhat like to thoſe of *Tragoriganum* Goats Marjerome, and about the ſame bigneſſe: the flowers are ſmall, made of many white threds ſet together, ſtanding betweene the leaves, this is wholly without either ſmell or taſte almoſt.

5. *Saxifraga Cretica altera Alpino.* *Alpinus* his other *Candy* Saxifrage.

They have alſo another kinde of Saxifrage growing in barren dry grounds, very like to a ſmall Pinke, for the leaves and manner of growing, but the flowers ſtand at the toppes of the branches in tufts or umbels of a pale reddiſh colour, this is of an aſtringent and drying taſte, with a little acrimony.

6. *Saxifraga montana Neapolitana.* Mountaine Saxifrage of *Naples*.

This ſmall Saxifrage which *Columna* found growing out of the Chinkes of rocky ſteepe hils, beareth two ſmall long leaves, at each joynt of the ſtalkes very like thoſe of *Matthiolus* his great Saxifrage, but ſomewhat broader ſofter, and whitiſh, with ſome ſmaller ones ſet with them likewiſe, where alſo riſe branches, bearing white flowers at the toppes, made of foure ſmall pointed leaves a peece, with divers ſmall threds in the middle and are ſucceeded by ſmall round skinny heades, with ſmall browne ſeede within them; the roote is made of many ſmall threds.

7. *Saxifraga maritima Neapolitana.* The Sea Saxifrage of *Naples*.

This is another ſort of the laſt deſcribed growing on the walls nigh the Sea at *Naples*, being twiſe as bigge, and having bluſh coloured flowers in Autumne and afterwards long pointed ſeed veſſels, and ſmall browne ſeede in them, this creepeth on the ground, and ſtandeth upright when it flowreth.

8. *Saxifraga Bavarica.* The Saxifrage of *Bavaria*.

The Saxifrage of *Bavaria*, ſpreadeth upon the ground, with a number of ſlender round branches, divided into others, ſet full of leaves, two at every joynt, which are narrow, ſomewhat long and thicke, and of a pale greene colour, at the toppe of every ſmall branch ſtandeth one flower, ſet in a ſmall cuppe or huske of whitiſh greene leaves, of which colour the ſtalkes are alſo, conſiſting of five ſmall pure white leaves, pointed at the ends, and ſometimes a little purfled about the brims, and with a waſh of purple, laid open like a little ſtarre, with ſome pale coloured threds in the middle, the ſeede that followeth in ſmal round and ſomewhat long heads, is ſmall, flat, blacke and ſhining, the roote is ſmall and white, and groweth downe ſomewhat deepe.

The Place and Time.

The firſt two ſorts grow in the Weſt parts of this land as *Lobel* ſaith, who relateth in his *Adverſaria*, that he found the ſecond betweene *Chipnam* and *Marleborough* in *London* high way to *Briſtow* on a chalky hill, yet *Matthiolus* ſaith, he had the firſt from *Mount Baldus* where it groweth, the third Mr. *Goodyer* ſaith, he found on a boggy ground below the red Well of *Wellingborough* in *Northamptonſhire*, the fourth and fifth in *Candy*, the ſixth and ſeaventh in *Naples*, and the laſt in *Bavaria*. They all flower late.

The Names.

Lobel and *Pena* ſay that the third Saxifrage of *Matthiolus* which ſome call *magna Matthioli*, and others *major Italorum* is the ſame which they have ſet forth in the firſt place, in their *Adverſaria*, although it grow not ſo great, and entitle it alſo *Saxifraga antiquiorum*, but I enterpoſed my opinion of that in the laſt Chapter, but *Bauhinus* ſuppoſeth them to be two ſeverall plants calling that of *Matthiolus Caryophyllus Saxifragus*, and that of *Lobel Caryophyllus Saxifragus ſtrigoſior*: the ſecond is a ſpecies as *Lobel* thinketh of the former, as is ſaid in the deſcription, and commeth neareſt to the ſecond ſort of *Candy* Saxifrage, but differing in the flowers, yet *Lobel* doubteth if it may not be a kinde of Chickeweede: but ſure he need not doubt it, nor that it was *Synanchice Dalechampij*. The third here expreſſed commeth nere likewiſe unto *Columna* his firſt *Neapolitane* Saxifrage, but that ours groweth in moriſh, and his in rocky places, and that the flowers of his have but foure leaves, and ours five round pointed, and his ſharpe. *Alpinus* maketh mention of the *Candy* kindes, and *Columna* of the *Neapolitane* which he entitleth *Alſme Saxifraga mantana & maritina*: the laſt *Camerarius* and *Pona* call *Saxifraga Bavarica*, but *Bauhinus* putteth a doubt or *quære* whether it be not the *Saxifraga magna Matthioli*, when as *Pona* in the deſcription of *mount Baldus*, mentioneth the *magna Matthioli*, in divers places thereof, and deſcribeth and giveth the figure of *Bavarica* diſtinctly.

The vertues.

The *Italians* doe wonderfully extoll with praiſes the vertues of their Saxifrages, and ſo doe the *Candiots* and *Neapolitanes* likewiſe, to breake and diſſolve the ſtone in the reines and kidneies, and bladder, and to procure urine, and to confirme the truth thereof, *Matthiolus* ſaith he received from *Calzolarius* an Apothecary of *Vecon*, ſuch great ſtones of ſundry perſons that were voided in making of their urine, that it could hardly be beleeved, that they could paſſe through the pipes from the bladder; to give him knowledge how powerfull in operation theſe are, that can expell the ſtone in the kidnies and bladder, be they never ſo great, the other Saxifrages except the third, have the ſame properties taken in wine, or in a draught of the decoction of them, with Quich graſſe rootes, doth effectually performe as much as the former, to diſſolve and breake the ſtone.

CHAP. VI.

Gramen Parnassi vulgare. The common grasse of *Parnassus*.

THis Grasse of *Parnassus* hath many leaves rising from the roote, not altogether round, but ending in a point, smaller and thicker than Violet leaves, with many ribbes or long veines in them, of a fresh greene colour, every one standing on a long foote stalke, among which there ariseth divers slender weake stalkes, scarse a foote high, and scarse able to stand upright, whereon grow at the severall joynts such like leaves, but smaller, without any foote stalke, but having the stalke joyning so close to it, that it seemeth almost to runne through it, the toppes of the stalkes are naked and bare of leaves unto the flowers for a good way, which are white and consist of five leaves standing round, and in the middle a small round greene head or button, with some yellow threds about them, which in time growing to be ripe is a round button, wherein is contained small reddish seede: the roote is a small blackish threddy bush of fibres, not perishing as divers of the former doe.

Gramen Parnassi duplicato flore. Double flowred Grasse of *Parnassus*.

This is in all things like the former, saving in the flower, which hath a row of smaller leaves, within the other outermost, which maketh a shew of the double flower: this seldome giveth any seede as the former,

The Place.

The first groweth in many moist moorish grounds in *England*, as in the Moore; neere *Lynton* and *Cambridge*, at *Hesset* and *Drinkestone* in *Suffolke*, in the Butchers close thereby; in a Medow close on the backeside of the Parsonage house of *Burton*, and at the bottome of *Barton* hills in *Beafordshire*; as also in the middle of the great Towne-field of *Hadington*, which is about a mile from *Oxford*, and on the other side of *Oxford*, in the pasture next unto *Botley* in the high way. The other was found in the country of *Brabant*.

The Time.

They flower not untill about Saint *James* tide, and the seede is ripe a moneth after.

The Names.

It is called *Gramen Parnassi*, and judged by most to be the right *Gramen Parnassi* of *Dioscorides*, although *Gesner in hortis Germaniæ* saith, that the right is not knowne to any in our dayes, but saith withall that the *Polonians* doe call it *Enneadynamis*. It is very probable, that this herbe grew most plentifully upon Mount *Parnassus*, whereon cattell feeding, became fat and well liking, as our Clover or three leaved grasse doth with us, and thereupon took the name, as is usuall in divers countries to call herbes by the name of Grasse, although they have no likenesse with Grasse indeede; and this may answer Mr. *Gerards* finding fault with the name of *Parnassus* Grasse. *Cordus*

Gramen Parnassi flore simplici.
Singl: *Parnassus* Grasse.

Gramen Parnassi duplici.
Double flowred *Parnassus* Grasse.

in

in his history of plants, calleth it *Hepatica alba*. *Gesner* in *Collectione stirpium Vnifolium palustre*, *Lobel* calleth it *Gramen Parnassi hederaceum recentiorum*. *Tabermontanus Gramen hederaceum* and *Flos hepaticus*. The other is called by *Lobel Gramen Parnassi duplicato flore*.

The Vertues.

Paulus Ægineta saith that *Parnassus* grasse, is temperately cold, of thinne parts, and somewhat sowre, the juice of the herbe, or the decoction thereof, or of the rootes, doth dissolve and expell stones and gravell from the reines and bladder gathered therein, and provoketh urine aboundantly; and the seede thereof taken in powder, worketh more forcibly then either the herbe or roote, and withall doth stay any vomitings from the stomacke, and any fluxe of the belly, the decoction of the rootes made with wine, being drunke, doth ease torments and griping paines in the bowels, and the ulcers that are in the bladder, it helpeth also against the biting of any venemous beast, the juice of the herbe or roote is good to coole any inflammation or heate in the eyes, to dry up the running or watering in them, and to cleare them from mistinesse or cloudy skinns, that obscure the sight, if it be mixed with a little hony and dropped into them: it is held also effectuall to ease the toothache, being gargled in the mouth: the herbe, or roote, or seede, either the juice, decoction or powder, is very effectually applyed to close up greene wounds, that are much subject to bleeding, and restraineth inflammations that may disease the party, or hinder the cure.

CHAP. VII.

Lachryma Iob. *Iobs* Teares.

I Have thought good to place this plant in a Chapter by it selfe, and not with the kindes of Gromel, because it differeth so much from them in growing, because the seede doth neerest resemble them: and although divers Authors have thought it rather to be a kind of grasse or reed, and therefore have placed it among them; yet I cannot finde it agree with either of them, more than in the jointed, stalkes, and leaves, which in my judgement, is not so sufficient a marke, to make it of that kinred, but as *Columna* saith, the flower and seede especially of plants, doth best demonstrate to what *genus* every *species* may be referred. It shooteth from a thicke bushie threddy roote, many reasonable thicke round jointed stalkes, about a foote and a halfe high, whereon at every joint standeth one narrow long, great leafe, somewhat like unto the leafe of Millet, or a small Reede, rather standing upright, than at any time bending downe; and at the joints with the leaves commeth forth one graine or seede, of the bignesse of a good Pease, wrapped in some huskes, round at the bottome, and pointed at the end, whereat hangeth two or three small chaffie huskes, or beards as *Pliny* calleth them, somewhat like unto small lanke short eares of corne, which are idle having nothing within them: the seede it selfe, being taken out of the skins, wherein it was wrapped, is somewhat like unto a Gromel-seede, but much larger, brighter of colour, and harder to breake, round yet pointed at the one end, somewhat flat also, and with an hole at the bigger and lower part, where it stood upon a little short foote stalke; the taste whereof being broken, and having but little kernell within it, is a little drying without any other manifest taste.

Lachryma Iob. *Iobs* Teares.

The Place.

This groweth naturally in the Iles of *Candy* and *Rhodes*, in *Syria* also and those Easterne Countries, but no where else in *Europe*, unlesse it be planted as it is said.

The Time.

It groweth slowly in our countrie and seldome giveth ripe seede for the want of sufficient heate of the Sunne to ripen it, before the frosts doe take it.

The Names.

It hath beene judged as I said before by former Authors, to be a kinde of Reede, and therefore *Gesner in hortis Germaniæ*, calleth it *Arundo lythospermos*, and so did *Matthiolus* account it, & found fault with *Fuschius*, that tooke it to be a kinde of *Lythospermon*, as *Tragus*, *Gesner*, and divers others, who called it *Lythospermum majus*. *Pena* and *Lobel* in their *Adversaria*, doe call it *Lythospermum Plinianum sive majus*, and doe very probably referre it to the *Lythospermon* of *Pliny*, *lib.* 27. *cap.* 11. (which hee there calleth *Diospiros*, *Iovis triticum*, which name is not so proper unto it, as the other *Lythospermum*, although the leaves hereof, are more like unto the blades of corne) but not of *Dioscorides*, who in the description confoundeth them both together, but in that he saith, the seede is of the bignesse of a Cich Pease, he doth most properly demonstrate this *Lythospermum*, for that of *Dioscorides*, which is our Gromell seede, is nothing so great, yet called also *Lythospermum fruticosum* of *Gesner*: it is now most usually called *Lachryma Christi* from the *Italians*, who when they first had it called it simply *Lagrima*; and since every severall countrie,

countrie, hath added another epithite thereunto: for the *Spaniards* call it *Lagryma de Moſen*; the *French* *L'armes de noſtre Dame*: the *Germanes* *Lachryma Iodoci*, as *Geſner* ſaith. *Lugduneuſis* calleth it *Lythoſpermum arundinaceum*, and *Bauhinus* *Lithoſpermum arundinaceum forte Dioſcoridis & Plinij, an Coix Theophraſtis lib. 1. cap. 16. hiſtoriæ plantarum*; we in *Engliſh* follow the titles, of almoſt all Nations; for ſome call it *Iobs* Teares, ſome *Moſes* Teares, or *Iobs* Droppes, or *Moſes* Droppe; *Chriſts* Teares, our *Ladies* Teares, and ſome Gromell reede according to *Geſner* his Latine. 7. b

The Vertues.

It is of little uſe in Phyſicke that we can underſtand in the naturall places, or where it may be had in more plenty than with us; yet ſome as *Pena* and *Lobel* ſay doe commend it, either in powder or the decoction thereof, againſt the ſtone or gravell in the kidnies and bladder: but beyond ſea, the greateſt uſe they make of it, is of the ſeede, to perforate and ſtring them, as other things for beades, to ſtint God with their prayers, and tell him how many they mumble upon them, and are ſure that they have done him ſo good ſervice therein, that he muſt needs give them heaven for it.

CHAP. VIII.

Lithoſpermum. Gromell.

THere are divers ſorts of Gromell found out and knowne to this later age, more than was to the former, and there are alſo ſome others that are ſomewhat like them, and therefore joyned unto them, although they participate with other plants: of them all I meane to ſpeake in this Chapter.

1. *Lithoſpermum majus erectum & legitimum.* Great upright Gromell.

The great Gromell riſeth up with divers upright, ſlender wooddy, hairy, browne and creſted ſtalkes, very little or not branched at all, whereon doe grow without order, long, hard, rough, and darke greene leaves, ſharper pointed and ſomewhat longer and narrower than the next: at the toppes of the ſtalkes ſtand divers ſmall white flowers, in rough browne huskes, wherein after they are paſt, is contained a white hard, ſtony, round, ſhining ſeede, like unto Pearles, and greater than the next: the roote is long and hard, or ſomewhat wooddy, with divers branches and fibres thereat, which periſheth not, although the ſtalkes die downe to the ground every yeare.

2. *Lithoſpermum majus ſive vulgare.* The greater creeping Gromell.

This kind of Gromell groweth up with ſlender hard and hairy ſtalkes, trailying and taking roote in the ground as it lyeth thereon, and parted into many other ſmaller branches, with ſuch like hairy darke greene leaves, but ſhorter and broader than the former: at the joints with the leaves come forth very ſmall blew flowers, and after them ſuch like hard ſtony roundiſh ſeede, but ſmaller and not fully ſo white and ſhining: the roote is like the former, abiding the Winter, and ſhooting forth ſtalkes freſh in the Spring, but giveth more plenty of ſeede, then the former, yet leſſer than the firſt.

2. *Lithoſpermum majus vulgare.*
The greater creeping Gromell.

3. *Lithoſpermum minus vulgaris.*
Small wilde Gromell.

The ſmall wilde Gromell ſendeth forth divers upright hard branched ſtalkes, full of joynts, to be two or three foote high, at every of which joints grow ſmall long hard, and rough leaves, leſſe than the laſt, and of a darke greene colour, among which leaves come forth ſmall white flowers, and in their places when they are paſt, grayiſh round ſeede like the other, the roote is not very long, but with many fibres faſtened thereto.

4. *Lithoſpermum anguſtifolium umbellatum.*
Vmbelliferous Gromell.

This Gromell ſpreadeth ſundry wooddy rough ſtalkes, yet eaſie to breake, ſpread into divers branches about halfe a foote high, with many very narrow rough leaves ſet on them without any order, the middle ribbe in them being ſomewhat great; the flowers ſtand at the toppes of the branches, and ſome times from the upper joynts, divers being ſet together as it were in an umbell which conſiſt of five ſmall round pointed leaves of a blew colour or rather being long and hollow are parted and cut into five parts ſet in rough greene huskes, wherein after the flowers are paſt growth uſually two white and hard long and pointed ſeedes ſet together: the roote is hard and wooddy covered with a browniſh red barke.

5. *Lithoſpermum Anchuſæ facie.*
Small Gromell with tufted toppes.

This ſmall Gromell hath many hard brittle, wooddy, low and hairy ſtalkes, riſing little above halfe a foote high, dividing themſelves even from the ground, into many ſmaller branches, whereon are ſet diſperſedly ſmall long and narrow rough greene leaves, whoſe middle ribbe riſeth up ſomewhat high: the flowers for the moſt part ſtand at the toppes of the branches in an umbell, divers tufting together, and ſometimes alſo at the joynts

3. *Lithospermum vulgare minus.*
Small wilde Gromell.

5. *Lithospermum Anchusæ facie.*
Small Gromell with tufted toppes.

6. *Lithospermum arvense radice rubente.*
Small corne Gromell.

Lithospermum Germanicum Passerina Tragi.
Germane Gromell or Sparrowort.

joynts with the leaves, ſtanding in rough huskes, which are ſomewhat larger then any of the other, and of a fine blew colour in ſome, in others white or reddiſh, to whom ſucceed ſmall and ſomewhat long pointed hard and white ſeede, two for the moſt part joyned together, the roote is long and wooddy, ſpreading under ground, covered with a rough browniſh red barke.

6. *Lithoſpermum arvenſe radice rubente.* Small corne Gromell.

This ſmall Corne Gromell, ſhooteth forth three or foure rough branches, divided into other ſmaller ones, having many ſmall long narrow hairy darke greene leaves growing on them, very like thoſe of the former Gromell, but not ſo hard or long, but ſet without order in the like manner, the flowers grow at the toppes, with many ſmall leaves among them, conſiſting of five ſmall white leaves, which after they are paſt, there ſucceed ſmall blackiſh ſeede, two, three, or foure ſet together in the ſame huske: the roote is ſomewhat reddiſh, but little or nothing colouring the fingers of them that touch it.

7. *Lithoſpermum minimum Germanicum, Paſſerina Tragi.* The ſmall *Germane* Gromell or Sparrow-wort.

The ſmall Gromell of *Germany* riſeth up for the moſt part, but with one ſlender ſtalke, branched into one or two parts at the moſt, ſcarſe a foote high, ſet here and there with ſmall long and narrow leaves, ſomewhat like unto Line or Flaxe, and whereon ſtand ſmall white flowers up towards the toppe, which turne into ſmall ſmooth round blackiſh ſeede, very like elſe unto Gromell ſeede, the roote is ſmall and threddy and periſheth every yeare.

8. *Lithoſpermum Linariæ folio Monſpelienſe.* *French* Gromell with flaxen leaves.

This kinde of Gromell hath likewiſe but one ſtalke, branched into two or three parts at the toppe thereof, whereon grow long and narrow leaves, ſomewhat larger then the former, and not rough as the other Gromels are: the flowers are ſmall, of a pale whitiſh yellow colour like unto the former, but ſtand many together at the toppes of the branches, and after they are paſt, ariſe ſmall round heads like Coriander ſeede, wherein is contained round hard blackiſh ſeede like unto Gromell, the roote is ſmall and ſtringy.

The Place.

The firſt groweth wilde in ſome places of *Italy*, and the parts of *France* next unto it, and not with us, but is onely nourſed up in the Gardens of thoſe that are lovers, and curious. The ſecond and third grow wilde in many places of our land, in barren or untilled places, and by the way ſides. The fourth *Bauhinus* ſaith was brought out of the Garden at *Padoa*, groweth as *Lobel* ſaith in the rough or ſtony deſcent of the valley of *Oſtia* in *Piemont*. The ſixt groweth in corne grounds in many places beyond the ſea, and in the way from *Briſtoll* to *Bath* as *Lobel* ſaith. The ſeaventh groweth in *Germany*, in the Corne fields by *Altzein*, and the thunder hill as *Tragus* ſaith, and in *Franconia* as *Camerarius* ſaith, betweene *Herbipolis* and *Frankford*. The laſt groweth about *Mompelier* in *France*.

The Time.

They doe all flower from Midſommer unto September ſometimes, and in the meane time the ſeed ripeneth.

The Names.

It is called in Greeke Λιθόσπερμον, *id eſt*, *Lapideum ſemen ob duritiem*, in Latine alſo *Lithoſpermum*. *Pliny* giveth it other names, as *Gorgonium*, *Æginochos*, *Heraclea*, and *Dyoſpiros*, but this name doth more fitly agree with the *Lachryma Iob*, as I ſhowed in the Chapter before, but indeed he confounderh both deſcriptions together, and the names alſo; and of Phiſitions and Apothecaries for the moſt part *Milium Solis*, and *Granum Solis*, *ab aliquibus ita dici putatur, quod ſemen candore ſolis & lucis ſplendore fulgeat*, but *Serapio* ſaith from the authority of *Aben Iulia*, that it ſhould be called *Milium Soler*, becauſe (the ſeedes being ſmall as *Milium*) it grew upon the mountaines called *Soler*, otherwiſe of the *Arabians* it is called *Kilb*, *Cult*, *Colt*, and *Calub*, of the *Italians* *Lithoſpermo*, and the leſſer kinde, *Milio Salvatico*, and *Milium Solis*, as *Caſtor Durantes* ſaith, of the *French* *Gremill*, and *L'herbe aux perles*, of the *Germanes Meerhirſz*, and *Steinſamen*, of the *Dutchmen Perlecruyt ende Steenſaet*, in *Engliſh* Gromell, Peare plant, and of ſome Lichwale. The firſt is called by *Brunfelſius Saxifraga tertia*, and is thought by *Bauhinus* to be the *Lithoſpermum minus* of *Matthiolus*, *Dodonæus*, and others, (and not his *majus*, which he ſeemeth not to know,) and yet calleth it *Lithoſpermum majus erectum*, and referreth it to the *Milium Solis ſativum* of *Tragus*, the *Lithoſpermum legitimum* of *Cluſius*, the *Lithoſpermum alterum fruticoſum* of *Iohannes Thalius*, in his deſcription of *Harcyniaſylva*, which by them all is ſaid to grow upright, and to differ from my ſecond, which *Cluſius*, *Dodonæus*, *Camerarius*, *Lobel*, and *Lugdunenſis* doe all call *majus* and *majus repens*; and yet *Bauhinus* calleth it *Lithoſpermum minus repens latifolium*, contrary to them all, he referreth this alſo to the *Pulmonaria minor Dalechampij*, which *Lugdunenſis* exhibiteth, which how truely I cannot well ſee, the third in my judgement is the *Lithoſpermum minus*, both of *Matthiolus*, *Dodonæus*, *Camerarius*, *Geſner*, *Lobel*, and others: the fourth *Bauhinus* calleth in his *Pinax*, *Lithoſpermum anguſtifolium umbellatum*, and there ſaith, he hath deſcribed it in his *Prodromus*, but I can finde none there expreſſed, but in the Appendix to his *Pinax*, in *folio* 521. it is briefly deſcribed, and more at large with the proper figure unto it by the name of *Lithoſpermum fruteſcens anguſtifolium* in his *Matthiolus*. The fifth is the *Lithoſpermum Anchuſæ facie* of *Lobel*, which *Bauhinus* calleth *Lithoſpermum minus erectum*, but I finde ſo little difference betweene theſe two laſt, that if any would take them to be both but one plant, I ſhould readily agree thereunto: the ſixt is the *Lithoſpermum ſylveſtre* of *Tragus*, *Fuſchius*, and *Camerarius* in his Epitome of *Matthiolus*, and the third of *Dodonæus*, the *Anchuſa degener facie Molij ſolis* of *Lobel*, the *Echium minus Lithoſpermo congener of Geſner* in his Appendix, the *Anchuſa arvenſis alba* of *Thalius*, and *Lithoſpermum arvenſe radice rubra* of *Bauhinus*, who likewiſe ſaith it is the *Lithoſpermum nigrum* of *Lugdunenſis*; but ſurely either *Lugdunenſis* is much miſtaken in his deſcription and figure, or *Bauhinus* in his reference and opinion: for *Lugdunenſis* deſcribeth it, and ſo the figure expreſſeth, to have many ſmall leaves ſet together at ſpaces about the ſtalkes, like as a ſmall Madder hath, which doth not correſpond with any *Lithoſpermum*. The ſeaventh *Tragus* and *Camerarius* call *Paſſerina*, and *Lingua Paſſerina*, and thereupon may be called Sparrw-wort, as well as ſmall Gromell with flaxen leaves, and is the fourth *Lithoſpermum* of *Dodonæus*, the *Paſſerina herbariorum uni caulis* of *Lobel* and *Pena*, *Lingua paſſerina* of *Tabermontanus*, *Paſſerina Linaria* of *Gerard*, reckoning it with the *Linaria's*, *Bauhinus* calleth it *Lithoſpermon Linariæ folio Germanicum*, and referreth it alſo unto the *Linaria altera botryodes montana* of *Fabius Columna*, whoſe deſcription and figure in my judgement doth utterly diſclaime it: the laſt he calleth *Lithoſpermum linariæ folio Monſpeliacum*, and *Lobel* and *Lugdunenſis* *Lithoſpermum linariæ folio*.

The Vertues.

The three firſt kindes are hot and dry in the ſecond degree, as all diuretick things for the moſt part are, and are both moſt (and I thinke onely) uſed, the reſt either not at all or very ſeldome, which if they ſhould, they are not found to be halfe ſo effectuall, as any of them, which are accounted to be of as ſingular force to breake the ſtone, and to avoid it and the gravell, engendred either in the reines or bladder, as alſo to provoke urine being ſtopped, and to helpe the ſtrangury or making of water by drops, as any other herbe or ſeede whatſoever: the ſeede is of greateſt uſe, and chiefly uſed to be bruiſed and boyled in white wine, or in broth or the like, or the powder of the ſeede taken in white wine, or in broth or the like, as a barley creame or Amond milke, made with the kernells of the foure greater cold ſeedes, and the ſeedes of Gromell boyled in the Barly-water, is both a pleaſant, ſafe, and effectuall medicine for the ſtone, to be drunk in the morning faſting, for three dayes together, when you are troubled with the fits thereof, this is *probatum* upon divers; *Matthiolus* ſaith, that if a dramm and a halfe of the ſeed of each of the Gromells (the greater and the leſſer he meaneth,) halfe a dramme of Spleenwort or Miltwaſt, and two ſcruples of white Amber, being all made into powder, mixed together and taken for many dayes together faſting, in the juice of Plantane, Purſlane, and Lettice, is ſingular good to helpe the *Gonorhæa* or running of the reines: two drammes alſo of the ſeede in powder, taken with womens breaſts milke, is very effectuall to procure a ſpeedy delivery, to ſuch women as have ſore paines in their travaile, and cannot be delivered; for with this onely medicine ſaith *Matthiolus*, he hath holpen many women in thoſe caſes: the herbe it ſelfe, when the ſeede is not to be had, either boyled, or the juice thereof drunk, is effectual to all the purpoſes aforeſaid, but not ſo powerful or ſpeedy in operation, the decoction alſo, to be bathed or fomented, as alſo to ſit in, is much commended for an outward remedy.

CHAP. IX.

Filipendula. *Filipipendula.* or Droppewort.

OF this *Filipipendula* or Droppewort, there hath beene formerly knowne but one kind, *Lugdunenſis* ſetteth forth one greater, and *Bauhinus* hath added thereunto another much leſſer; *Dodonæus*, *Lobel* and others, have called another plant *Filipendula montana*, which *Cluſius* calleth *Alectorolophos Alpina*, as a ſpecies thereof, but I dare not allow of their opinions therein, not finding them to agree, in rootes, or flowers, or ſeede, and but a little in leaves: I will therefore ſpeake in this Chapter of the ordinary ſorts, and of the others in the next, but for the *Oenanthes* (as they are ſo called) and by that name knowne to us in theſe dayes, becauſe they be rather umbelliferous plants, I thinke it fitter to ſpeake of them in that Claſſis of umbelliferous plants, with the other Saxifrages that are of that Tribe, then joyne them together with theſe.

1. *Filipendula vulgaris.* Common or ordinary *Filipendula.*

This *Filipendula* ſhooteth forth divers long winged leaves, that is, many ſmall leaves, ſome bigger and ſome leſſer, ſet on each ſide of a middle ribbe, and each of them dented about the edges, ſomewhat reſembling Burnet and wild Tanſy, or rather Agrimony, or betweene them all, but harder in handling, among which leaves ariſeth up one or more ſtalkes, two or three foote high, having ſome ſuch leaves thereon as grow below, and ſometimes alſo divided into other branches, ſpreading at the toppe, into many white ſweete ſmelling flowers, conſiſting of five leaves a peece, with ſome threds in the middle of them, ſtanding together in a tuft or umbell, each upon a ſmall footeſtalke, which after they have abiden a good while open and blowne, doe fall away, and in their places appeare ſmall round chaffy heads like buttons, wherein are the chaffy ſeed ſet and placed, the roote conſiſteth of many ſmall blacke tuberous peeces, faſtened together by many ſmall long blackiſh ſtrings, which runne from one unto another.

2. *Filipendula altera major.* Another great *Filipendula.*

This other *Filipendula* is ſo like the former in the leaves, that it can ſcarſe be diſcerned from the other, the flowers at the toppe of the ſtalke, are of a white enclining to a purple, made of five leaves a peece like the other, after which the heads beare round and blackiſh ſeede within them, the rootes are very many, and ſomewhat longer and whiter, enclining to redneſſe, but faſtned together by long ſtrings and fibres as the former.

3. *Filipendula minor.* Small *Filipendula.*

The ſmall *Filipendula* hath two or three ſuch like leaves as the former, riſing from the roote, but much ſmaller, and more neerely reſembling the wild Tanſy leaves, but not white as they are, but of the ſame darke greene colour with the former; from among which, the ſtalke that is ſcarſe an handbredth high, ariſeth up ſometimes without diviſion therein, and ſometimes alſo parted into two or three other branches; whereon ſtand many ſmaller white ſweeter flowers then the former, but with threds therein like them, and ſet together in an umbell in the ſame manner; after which come the ſeede, many ſet together, formed almoſt like unto a ſmall bunch of grapes, the rootes are many, and glandulous or tuberous like the former, but ſmaller and redder, yet tyed together by ſtrings like them.

The Place.

The firſt is common in many places of this Land, as well upon and about St. *Vincents* rocke, by *Briſtow*, and neare *Sion* in the meddow there, as alſo in the corners of dry fields and meddowes, and their hedges ſides, the ſecond as *Lugdunenſis* ſaith, groweth on the toppes of very cold mountaines, the laſt was found in the ſtony rough grounds about *Mompelier*.

The Time.

They flower in *Iune* and *Iuly*, and their ſeede ripeneth in *Auguſt*.

The Names.

This is taken by many learned writers, and herbariſts in theſe dayes, to be the Οἰναν θη *Oenanthe* of *Dioſcorides*, which he deſcribeth in his third booke and 132. Chapter, and not that *Oenanthe* which he ſaith in his fifth booke is the flower of the wild Vine, that beareth onely flowers and not grapes, and becauſe that *Matthiolus* conteſteth againſt *Fuſchius*, to whom *Brunfelſius* and *Tragus* doe agree, for ſo holding it, *Lobel* in his *Adverſaria* would

ſeeme

1. *Filipendula major.*
The greater common *Filipendula.*

3. *Filipendula minor.*
The leſſer *Filipendula.*

ſeeme to maintaine *Fuſchius* opinion againſt *Matthiolus*, proving as he thinketh, every part of *Dioſcorides* his deſcription to agree thereunto; yet ſtil *Matthiolus* his aſſertions will hold good againſt *Fuſchius* and *Lobel* that this *Filipendula* agreeth not with *Dioſcorides* his *Oenanthe*, eſpecially in the ſeedes, for it is ſuch an eminent marke that none can alter or gainſay. It is called of all moderne writers *Filipendula, quod numeroſi illi in radice bulbilli, quaſi ex filo pendere videantur*, ſome write it *Philipendula*, becauſe *Nicholaus Myrepſus* called it φιλιπένδουλα. Some thinke this to be *Molon* of *Pliny*, whereof he maketh mention in his 26. booke, and 7. chapter, but it is doubtfull: the *Italians* and *Spaniards* call it *Filipendula*, and the *French Filipende* and *Filipendule*, the *Germanes Rotten Steinbrech*, that is, red breakeſtone, from whence came the Latine name among them *Saxifraga rubra*, red Saxifrage; as alſo *wild Garb*, that is *Milleſolium ſylveſtre*: we call it *Filipendula*, and ſome *Filipipendula* and Dropwort. The ſecond *Lugdunenſis* calleth *Oenanthe alia Myconi*, becauſe he ſaith it is ſo like the ordinary *Filipendula*, both in outward forme and face of growing, in rootes and leaves, and in the taſt and relliſh alſo, and not unlikely thereby to be of the ſame vertue and property, but *Bauhinus* referreth it rather to the next *Filipendula montana*, whereof I cannot ſee any reaſon, for in my opinion it is the ſame with the former, and not a ſpecies of the next, let others be judge herein that are judicious. The laſt *Bauhinus* ſetteth forth by the name of *Filipendula minor*.

The Vertues.

The ordinary or vulgar *Filipendula* is ſomewhat bitter in taſte, and thereupon judged to be hot and dry in the third degree, it is very effectuall to open the paſſages of the urine, when it is ſtayed, as alſo to helpe the Strangury, and all other paines of the bladder and reines, helping mightily to breake and expell the ſtone, either in the kidneyes or bladder, and gravell alſo that is not as yet condenſate into a ſtone, whether you will uſe the leaves, flowers, or ſeede, but the rootes are moſt uſuall and moſt effectuall, either taken in powder or in a decoction with white wine, whereunto a little honey is added: the ſame alſo helpeth to expell the *ſecondine* or afterbirth, taken in the ſame manner: an ancient copy of *Dioſcorides* ſaith, it helpeth alſo the yellow Iaundiſe, *Paulus Ægineta* ſaith, it is good for thoſe that have the falling ſickneſſe, and that it will helpe them if they uſe it often: the rootes made into powder, and mixed up with hony, into the forme of an electuary, doth much helpe them whoſe ſtomakes are ſwollen, breaking and diſſolving the winde which was the cauſe thereof, as alſo is very effectuall for all the diſeaſes of the lungs, as ſhortneſſe of breath, wheeſings, hoarſeneſſe of the throate, and the cough, and to expectorate cold flegme therefrom, or any other parts thereabouts.

CHAP. X.

Filipendula montana. Mountaine or Hooded *Filipendula* or Droppewort.

CLuſius and others have made mention of divers ſorts of this kinde of *Filipendula*, (if I may ſo call it, for I doe herein rather pleaſe others than my ſelfe, who thinke them with *Clauſius*, to be as unlike them in forme, as differing alſo in qualitie peradventure) yet becauſe ſuch learned men have ſo accounted of ſome of them, let me in their errour be joyned with them for this time.

1. *Filipendula montana major albida.*

Whitiſh Mountaine or hooded *Filipendula.*

This firſt hooded Mountaine *Filipendula*, ſhooteth forth his round creſted or ſtreaked ſtalkes, of a fingers thickeneſſe and a cubites height, whereon are ſet winges of many cut and divided leaves, on each ſide of them, from the bottome to the toppe, ſomewhat like thoſe of the former *Filipendula*, or betweene them and Yarrow, but hard and ſomewhat rough in handling, whereon are growing a long ſpiked head of whitiſh flowers, formed like the gaping hoodes of the Satyrions or Teſticles, called Cullions or Dogges ſtones, every one ſet in a five leafed huske, which being fallen, there follow round heades, pointed at the toppes, wherein are contained, much ſmall grayiſh ſeede: the rootes are many long and thicke ſtrings, ſomewhat like unto the Aſphodill clogges, but not ſo great, which are ſet together at the heads, and ending in long fibres, abiding many yeares, and ſhooting freſh leaves and ſtalkes in the Spring, although the old die downe to the ground and wither.

Filipendula montana mollior altera.

Filipendula montana.
Mountaine *Filipendula.*

2. *Filipendula montana mollior altera.*

Smooth mountaine or hooded *Filipendula.*

This other mountaine *Filipendula*, hath ſuch like ſtalkes, with long & divided leaves on them, in the like manner, not differing from them, but in that they are nothing hard, but very gentle and ſmooth in handling; the flowers grow likewiſe at the toppes of the ſtalkes, in a long ſpiked head, many ſet together, and in forme hooded like them, but are in ſome of a pale whitiſh yellow colour, and in other of a reddiſh purple: the rootes alſo are not ſo great and thicke, but rather like Aſparagus rootes.

The Place.

Both theſe ſorts grow as *Cluſius* ſaith, on the graſſie places, in the mountaines of *Auſtria* and *Stiria*, in *Flanders* alſo, and in *France* in their Medowes.

The Time.

They flower in *Iune*, and ripen their ſeede in *Auguſt.*

The Names.

Pena and *Lobel* doe call the firſt of theſe *Filipendula altera montana*, and ſo doe alſo *Dodonæus* and *Tabermontanus*, but *Cluſius* doth rather referre both it and the other unto the *Fiſtularia* or *Pedicularis* for that they neereſt reſemble it in forme, excepting the rootes, and thereupon calleth them *Alectorolophus Alpina*: *Bauhinus* calleth it *Filipendula montana flore pedicularię*, and with all maketh it to be that *Oenanthe alia Miconi* of *Lugdunenſis*, which is more probably another ſort, of the former and true *Filipendula*, as I have ſhewed you in the Chapter before. The ſecond *Cluſius* calleth *Alectorolophus Alpina ſecunda vel altera*; and *Bauhinus Filipendula montana altera*; I have, as I ſaid before, followed them in this their errour, and doe call them in *Engliſh* Mountaine or Hooded *Filipendula*, according to the *Latine.*

The Vertues.

I do not finde any vertues appropriate peculiarly to theſe plants, either by *Cluſius* or any other that have mentioned them, and unles they have the ſame qualities that the Yellow or red Rattle have, which ſome call Louſewort, becauſe if ſheepe feede thereon, it will cauſe them to breede lice abundantly: they muſt abide without uſe to us.

CHAP. XI.

Helxine ſive Parietaria. Paritary of the Wall.

THere are two ſorts of Paritary of the Wall, although the ancients have mentioned but one, that is a greater and a leſſer, as ſhall be declared.

1. *Paritaria vulgaris.* Common Paritary of the Wall.

This kinde of Paritary, or (as it is uſually called) Pellitory of the Wall, riſeth up with many browniſh red, tender and weake, cleare, and almoſt tranſparent ſtalkes, about two foote high, upon which grow at the ſeverall joynts, two leaves ſomewhat broad and long, like unto thoſe of *French* Mercury, or

Amaranthus

Amaranthus called Flower gentle, of a darke greene, which afterwards turne browniſh, not dented at all, but ſmooth on the edges, rough and hairy as the ſtalkes are alſo: at the joynts with the leaves, from the middle of the ſtalkes upwards, where it ſpreadeth into ſome branches, ſtand many ſmall pale purpliſh flowers, in hairy, or ſomewhat rough heades or huskes, after which come ſmall blacke and rough ſeede, which will ſticke to any garment or cloath that ſhall touch it: the roote is ſomewhat long with many ſmall fibres annexed thereunto, of a darke reddiſh colour, which abideth the Winter, although the ſtalkes with leaves periſh, and ſpringeth a freſh every yeare.

2. *Parietaria minor.* Small Pellitory of the Wall.

The leſſer Pellitory of the Wall, groweth in the like manner that the former doth, but not ſo great or high, having tender reddiſh rough ſtalkes, and ſmaller and ſhorter, and ſomewhat greener leaves thereon, almoſt like unto Baſſil, and rougher alſo, ſo that they will cleave to any cloth, or otherthing that toucheth it; the flowers and ſeede differ not much from the other, but ſmaller, and the ſeede is more like unto Purſlane ſeede, being rubbed out of the huskes, han the other.

The Place.

The firſt groweth wilde generally through the land, about the borders of fields, and by the ſides of old Walls, and among rubbiſh: it will well endure alſo being brought into the garden, and planted on the ſhadie ſide, where it will ſpring of its owne ſowing, and will not eaſily be gotten out therehence afterwards: The other is rare in our Countrie, and in *Germany* alſo, but neare *Confluence*, where it is naturally found, and not in many other places, neither both of them in one place or very ſeldome, it doth ſometimes hold the greene leaves in the Winter.

The Time.

They flower in *Iune* and *Iuly*, and the ſeede is ripe ſoone after.

The Names.

It is called in Greeke ἑλξίνη *Helxine*, and περδίκιον, *Perdicium*, the one *quod foliorum & ſeminum hirſutie veſtibus adhæreat*: the other *quod perdices ea libenter veſcantur*: in Latine alſo *Helxine*, (but not *Ciſſampelos*, which is deſcribed before,) *Perdicium*, *Perdicaria*, & *Vrceolaris*, *Vitrago* or *Vitriolaris herba*, becauſe the roughneſſe thereof ſerveth to cleanſe either pots or glaſſes; it is called alſo *Muralium*, and *herba Muralis*, becauſe it moſt uſually groweth by Walls ſides, and for the ſame cauſe alſo it is called *Parietaria*, or as ſome doe write it *Paritaria*. *Galen* and *Paulus Ægineta*, who followeth him in moſt things, ſay, that ſome in their dayes called it *Parthenium*, but they doe not underſtand the *Matricaria* for it, but this herbe here entreated of; but there are to be found in the writings of divers, that have written of herbes ſeven ſeverall ſorts of herbes, called by the name *Parthenion* or *Parthenium*; as *Mercurialis*, *Arthemiſia*, *Chamomilla nobilis*, *Amaracus* or *Majorana*, *Marum*, *Matricaria*; and this *Parietaria*; *Cornelius Celſus* alſo, and *Pliny* out of him, doe call it *Parthenium*; and yet *Leonicenus*, *Colmarius*, and *Rudolphus Agricola*, much doubted, whether any did ſo call it: the *Italians* call it *Parietaria* & *Vitriola*; the *Spaniards yerva de muro*; the *French Paritoire* and *Paritari*; the *Germanes San Peters kraut*; as *Tragus* ſaith, & *Tag unnacht* and *Glaſzkraut*; the *Dutchmen Glaſſcruidt*; in *Engliſh* ordinary Pellitory of the Wall, but corruptly as I ſaid, for it hath no correſpondencie with Pellitory; but to follow the Latine name, as moſt other Countries doe, it ſhould be called Paritarie, and of the wall is added according to both the names of *Paritaria* and *Muralis*; all Authors doe call it generally either *Helxine* or *Parietaria*, and *Tragus* calleth the other *Paritaria exigua*.

1. *Parietaria vulgaris.*
Common Pellitory of the Wall.

The Vertues.

The dried herbe Paritary made up with hony into an Electuarie, or the juice of the herbe, or the decoction thereof made up with Sugar or Hony, is a ſingular remedy for any old continuall or dry cough, the ſhortneſſe of breath and wheezings in the throate: the juyce thereof taken to the quantie of three ounces at a time doth wonderfully eaſe thoſe that are troubled with the ſuppreſſion of their urine, cauſing them very ſpeedily to make water, aud to expell both the ſtone and gravell that are engendred in the kidnies and bladder, and therefore it is uſually put among other herbes that are uſed in gliſters, to mittigate paines in the backe, ſides, or bowells, proceeding of winds or the like ſtoppings of urine, or the gravell and ſtone: it worketh the like effect alſo, if the bruiſed herbe ſprinkled with ſome Muskadine be warmed upon a tyle, or in a diſh upon a few quicke coales in a Chaffing diſh, and applied to the belly: the decoction alſo of the herbe being drunke, eaſeth the paines of the mother, and bringeth downe the courſes that are ſtaied; the ſame alſo eaſeth thoſe griefes that ariſe from the obſtructions of the liver, ſpleene, and reines: the ſame decoction alſo may ſerve in ſtead of a bath for men or women to ſit in, for the foreſaid purpoſes: the ſame decoction alſo with a little hony added thereto, will ſerve to very good purpoſe to gargle the throate when it is ſwollen and pained; the juice held a while in the mouth eaſeth the paines in the teeth: the diſtilled water of the herbe drunk with ſome Sugar to make it the more pleaſant, worketh the ſame effects, and moreover cleanſeth the skinne from ſpots, freckles, purples, wheales, ſunburne, morphew, &c. and leaveth the skinne, cleare, ſmooth and delicate: the juyce dropped into the eares eaſeth the noiſe and

hummings in them, and taketh away the prickings and ſhooting paines in them: the ſaid juyce or the diſtilled water, doth aſſwage hot and ſwelling impoſtumes, burnings or ſcaldings by fire or water, as alſo all other hot tumours or imflammations, be it Saint *Anthonies* fire, or any other eruptions of heate, being bathed often with wet cloths dipped therein; or the ſaid juice made into a liniment with *Ceruſſa* & oyle of Roſes, & anointed therewith, which alſo doth clenſe foule rotten ulcers, and ſtaieth ſpreading or creeping ulcers, and the running ſcabbes or ſores in childrens heads: the ſame alſo helpeth to ſtay the falling of the haire of the head; the ſaid ointment or the herbe applied to the fundament, openeth the piles, and eaſeth their paines, and being mixed with Goates tallow, or the *Cyprian Cerote*, doth helpe the gout: the juyce is very effectuall to clenſe fiſtulaes, and to heale them up ſafely, or the herbe it ſelfe bruiſed and applied with a little ſalt: it is likewiſe ſo effectuall to heale any greene wound, that if it be bruiſed and bound thereto for three dayes, you may afterwards take it away, for you ſhall not neede any other ſalve or medicine to heale it further: a pultis made hereof with Mallowes, and boyled in wine with Wheate branne, and Beane flower, and ſome oyle put thereto, and applied warme to any bruiſed ſinew, tendone, or muſcle, doth in a very ſhort time reſtore them to their ſtrength, and taketh away the paines of the bruiſes, and diſſolveth the congealed bloud of any beatings, or falls from high places.

CHAP. XII.

Heliotropium. Turneſole.

THere are divers ſorts of herbes that may be called Sunturners, becauſe their flowers doe oppoſe the Sunne, whereof to ſpeake in this place is not my purpoſe, neither will the method of the worke admit: but properly of that kinde ſo called, whereof there are three or foure ſorts, as ſhall be preſently declared.

1. *Heliotropium majus.* The greater Turnſole.

The grrater Turneſole riſeth up with one upright ſtalke, about a foote or more high, dividing it ſelfe almoſt from the bottome into divers ſmaller branches, of a hoary colour; at each joynt of the ſtalke and branches grow two ſmall broad leaves, ſomewhat like unto thoſe of Calamint or Baſil, but greater than Calamint, and leſſer than the greater Baſill, ſomewhat white or hoary alſo: at the toppes of the ſtalkes and branches, ſtand many ſmall white flowers, conſiſting of foure and ſometimes of five very ſmall leaves, ſet in order, one above another, upon a ſmall crooked ſpike, which turneth inwards like a bowed finger, opening by degrees as the flowers blow open; after wich in their places come ſmall cornered ſeede, foure for the moſt part ſtanding together: the roote is ſmall and threddy, periſhing every yeare, and the ſeede ſhedding it ſelfe, riſeth againe the next Spring.

2. *Heliotropium majus ſupinum.* The greater creeping Turneſole.

This creeping Turneſole according to the judgement of *Cluſius*, is in a manner but the ſame with the former greater Turneſole, becauſe it is in moſt things ſo like it, yet differeth in theſe particulars, that it hath more and ſlenderer ſtalkes, not ſtanding upright as the former doth but leaneth downe to the ground, the ſtalkes and leaves are leſſer, but hoary in the like manner; the flowers are white, and ſtand in crooked ſpiked heads, bowing like a Scorpions taile, as the other, but the ſeede being ſmaller, ſtandeth ſingly, or but two together; the rootes are ſmall and periſh in like manner.

1. *Heliotropium majus.*
The greater Turneſole.

3. *Heliotropium minus.*
The ſmall Turneſole.

3. *Heliotropium minus.* The ſmaller Turneſole.

This ſmaller Turneſole groweth very low, lying almoſt with his ſlender weake branches upon the ground, having thereon many ſmall leaves, like the other in forme, but three times leſſe in ſubſtance, neither ſtalkes nor leaves white nor hoary, but of a darke greene colour: the flowers are much ſmaller and yellowiſh, not growing in long crooked or bowing heads like the former, nor at the toppes of the branches, but ſtanding at the joynts, upon very ſmall ſtalkes, ſome above the leaves and others under them, which afterwards turne into ſmall round heads or buttons, like unto wartes, wherein is ſuch like ſeede as the reſt, but ſmaller and a little rounder.

4. *Heliotropium tricoccum.* The colouring or dying Turneſole.

This dying Turneſole that beareth berries, three alwayes ſet together, riſeth up with an upright ſtalke, branching it ſelfe diverſly to the height of halfe a yeard or there abouts; whereon grow broader and ſofter leaves than any of former, like unto thoſe of the ſleepy Night-ſhade, & whitiſh withall, ſet without order at the joynts up to the toppes, yet leſſer above than below: at the end of the branches come forth ſmall moſſie yellowiſh flowers, which quickly periſh and fall away without giving any ſeede, herein like unto the *Ricinus* or *Palma Chriſti*, called the great Spurge; for in the ſame manner alſo, at the joynts with the leaves come forth the fruit or berries, ſtanding three for the moſt part alwayes joyned together upon ſhort foote ſtalkes, which are of a blackiſh greene colour, and rough or rugged on the outſide, within which is contained aſhcoloured ſeede, which if the heads be ſuffered to grow to be overripe, and be dried with the Sunne, will fall out of themſelves upon the ground, and ſpring againe in their naturall places the next yeare, thereby renewing it ſelfe, for the roote is ſmall, and periſheth after it hath borne ſeede: but theſe berries when they are at their full maturitie, have within them that is betweene the outer skinne and the inner kernell or ſeede a certaine juice or moiſture, which being rubbed upon paper or cloth, at the firſt appeareth, of a freſh and lively greene colour, but preſently changeth into a kind of blewiſh purple upon the cloth or paper, and the ſame cloth afterwards wet in water and wrung forth, will colour the water into a claret wine colour; and theſe are thoſe ragges of cloth, which are uſually called Turneſole, in the Druggiſts and Grocers ſhoppes, and with all other people, and ſerveth to colour jellies, or other things as every one pleaſe.

4. *Heliotropium tricoccum.*
The colouring or dying Turneſole.

The Place.

Theſe doe grow in *Italy*, *Spaine* and *France* in divers places, as *Matthiolus*, *Lobel* and *Cluſius* doe ſet them downe: the two firſt doe well endure with us.

The Time.

The two firſt doe flower and ſeede well with us every yeare, but the other two doe ſcarce beare any ſhew of ſeede with us, in regard we want ſufficient heate to ripen them.

The Names.

It is called in Greeke ἡλιοτρόπιον *Heliotropion*, that is, *Soliſequium* Sunturner, ſo called ſaith *Dioſcorides*, *quoniam folia cum ſole circumagantur*; but herein I thinke he erred, for the leaves doe not turne to the Sunne, onely the head of flowers faceth the Sunne; and is called alſo σκορπιοῦρον *Scorpiurum*, *quia ſpica florum Scorpionis caudæ eſt effigie*; but *Theophraſtus* ſaith, it is called *Heliotropium*, becauſe it flowreth in the Sommer *Solſtice*: the ſmall kinde is called moſt properly in Latine *Verrucaria*, *a tollendis verrucis*, and *Herba Cancri*: the *Italians* call it *Heliotropio*, and the *Spaniards Tornaſolbobo*; but the *Spaniards* and *French* call the laſt *Turnaſol* and *Turneſol*. The firſt is generally called of all Authors *Heliotropium*, and *Verrucaria* of ſome, onely *Geſner in hortis*, calleth it *Scorpioides album*, and *Lonicerus Herba Cancri major*: the ſecond *Cluſius*, *Dodonæus* and *Geſner* call *Heliotropium ſupinum*, *Lugdunenſis Heliotropium humi ſparſum Cluſij*, and *Bauhinus minus ſupinum*: the third is called *Heliotropium minus repens* of *Lobel*, and of *Geſner Heliotropium minus folio ocimi*; *Lugdunenſis* calleth it *Verrucaria altera minor*; the laſt is called *Holiotropium tricoccum* of *Pliny*, and all others ſince his time, yet ſome adde unto it *minus*. *Camerarius in horto*, ſaith it is called *Herba Clitiæ*, and thereupon the Poet hath theſe Verſes;

Herba velut Clitiæ ſemper petit obvia Solem,
Sic pia mens Chriſtum quo prece ſpectet habet.

Lobel calleth it *Heliotropium vulgare Turneſol Gallorum, ſive Plinij tricoccum*, and in his Obſervations, *Heliotropium parvum Dioſcoridis*, being ſuppoſed by many to be deſcribed by *Dioſcorides* under the *minus*, although hee did not particularly name it.

The Vertues.

Dioſcorides ſaith that a good handfull of the greater Turneſole boyled in water and drunke: purgeth both choller

choller and flegme, and being boyled in wine, it is good againſt the ſtingings of Scorpions, to be as well drunke as laid upon the place that is ſtung: the ſame alſo boiled with Cummin and drunke, helpeth them that are troubled with the ſtone in the reines or kidnies or bladder, provoketh urine and womens courſes, cauſeth an eaſie and ſpeedy birth, when they are in travell; it killeth the wormes of the belly both long and round, if the herbe and ſeede of the leſſer kinde be taken with Hyſſope, Creſſes, and Nitar. *Pliny* ſaith that the *Magi* in his time held this opinion, (idle as many other his relations are) that foure graines or ſeedes of his Turneſole drunke in wine, an houre before the acceſſe of the fit of the *quartaine* ague doth cure it, and that three graines drunke in the ſame manner will helpe the *tertian*: the leaves bruiſed and applyed to the places pained with the gout, or that are out of joynt, and being ſet are full of paine, doth give much eaſe, as alſo for children that have the diſeaſe called *Syriaſis*, which is an inflammation of the parts about the braine, and the *tunicles* thereof; the ſeed of the leaſt kinde (but the greater will doe the ſame alſo) and the juice of the leaves alſo being rubbed with a little ſalt upon warts, ſwollen wens, and other hard kernels or excreſſences, in the face, eye-lids, or any other parts of the body, will take them away, by conſuming them a little and a little, with often uſing it: The dying or colouring Turneſole is alſo good againſt all venemous creatures, and chiefly againſt that great Spider *Phalanginm*, and to cauſe the ſting of Scorpions to be without danger or paine, being applyed thereto: it is ſaid alſo that if one make a circle upon the ground, round about a Scorpion with a branch of this Turneſole, it ſhall not be able to get out of the circle, but if any ſhall touch the Scorpion therewith, or caſt any of the herbe upon it, it ſhall preſently dye: we have no other uſe of thoſe clouts that are dyed with the juice thereof, then to colour gellies or tarts, or any other ſuch things which are frequent in many great mens houſes at Feſtivall times.

CHAP. XIII.

Vrtica. Nettles.

I Shall in this place onely ſhew you thoſe Nettles that are ſtinging, as peculiar for this Claſſis or Tribe, but if I were to write an univerſall compacted hiſtory together, which the method I have propoſed doth not permit; I would then in this as in all others, joyne all the *ſpecies* under one *genus*, and ſhew you all the diverſities of them, as well thoſe that are ſharpe and ſtinging, as thoſe that are not, but called Dead Nettles, and in them ſuch as ſmell well, and ſuch as ſtinke, and ſuch as are ſpotted, and ſuch as are without ſpots, and ſo likewiſe their variation of colours in their flowers, which becauſe I cannot in one, I muſt doe in ſeverall places of this worke.

1. *Vrtica Romana.* The Romane Nettle.

The great Romane Nettle groweth up with many round hairy branches, rather leaning downe then ſtanding upright, ſometimes riſing to be of foure or five foote long, ſpreading into many branches, whereon at the joynts

1. *Vrtica Romana.*
The Romane Nettle.

2. *Vrtica major vulgaris.*
The greater wilde Nettle.

3. *Vrtica media ſylveſtris.*
The middle wild Nettle.

4. *Vrtica minor.*
The leſſer wild Nettle.

are two leaves ſet together, very rough, and although it hath no ſharpē prickles, yet it hath a hairy downē thereon, that will ſting the skinne moſt cruelly if it be touched therewith, and raiſe it full of bliſters, as if it were burnt with fire, and dented at the edges ſomewhat deepely; at divers places of the branches come forth ſmall ſtalkes of reddiſh and yellowiſh flowers, made of threds, which fall away without bearing any thing elſe; but at the joynts with the leaves in other places, from the middle of the branches upwards, come forth ſmall, round, rough, greene, prickly pellets or buttons, wherein is contained divers flat browne ſhining ſeede, ſomewhat like unto Linc, or Flax ſeede, but ſmaller and rounder: the roote is yellowiſh and ſpreadeth divers long ſtrings, and ſmall fibres, whereby it taketh faſt hold in the ground, yet periſheth every yeare, requiring a new ſowing every Spring.

2. *Vrtica major ſylveſtris.* The greater wild Nettle.

This other which is the greater of the wild ſorts, hath a pale yellow roote, ſpreading very deepe into the ground, with long ſtrings, and ſmall fibres, and the branches alſo lying on the ground take roote againe, and ſpread a great deale of ground, the leaves are of a darker colour, and ſometimes browniſh or red, as large, rough and ſtinging as the former, but not ſo deepely dented at the edges; at the toppes of the branches, and likewiſe from the joynts with the leaves underneath, come forth ſmall long branches of flowers and ſeedes after them, in faſhion very like the branches of the female Mercury, wherein is contained ſmall flat whitiſh ſeede, the roote periſheth not like the former, but abideth the winter with ſome greene leaves upon it, if it be not too extreame.

3. *Vrtica media ſylveſtris.* The middle wild Nettle.

The middle ſort of Nettle, is thought by divers to be but one and the ſame with the formēr, and differing onely by the place of growing, and not growing fully ſo great: for it hath the like ſtalkes and branches, with the like leaves, but lower and ſmaller, and thinner ſet upon the branches, otherwiſe in ſeede or creeping rootes, it differeth not from the laſt.

4. *Vrtica minor ſylveſtris.* The leſſer wild Nettle.

The leſſer or leaſt Nettle, is in moſt things like the laſt, but riſeth ſeldome above halfe a yard high, and little or nothing branched, the leaves alſo are much ſmaller, and of a freſher greene colour, but little leſſe ſtinging then the former; the ſeed is white like unto it, but the rootes are ſmaller and periſh every yeare, yea twiſe or thrice every yeare, for I have obſerved it to ſhed it ſelfe twiſe in a hot yeare, and ſpring up againe the third time of the ſhedde ſeede, which being neere winter, periſheth with the firſt froſts, but riſeth againe the next yeare.

The Place.

The firſt is moſt uſually ſowen in Gardens where it is deſired, as it is alſo both in the upper and lowēr *Germany*, and moſt places of *France* alſo, but it hath beene found naturally growing time out of minde, both at the towne of *Lidde* by *Romney*, and in the ſtreetes of the towne of *Romney* in *Kent*, where it is recorded *Iulius Cæſar* landed with his ſouldiers, and there abode for a certaine time, which it is likely was by them called *Romania* and corruptly there-from *Romeney* or *Romny*, and for the growing of it in that place, it is reported that the ſouldiers brought

brought ſome of the ſeede with them, and ſowed it there for their uſe, to rubbe and chafe their limbes, when through extreame cold they ſhould be ſtiffe and benummed; being told before they came from home, that the climate of *Brittaine* was ſo extreame cold, that it was not to be endured without ſome friction or rubbing, to warme their bloods, and to ſtirre up naturall heat, ſince which time it is thought it hath continued there, riſing yearely of its owne ſowing. It groweth alſo in the ſtreete of *Bardney* in *Lincolneſhire*. The other three ſorts grow in waſte grounds, by hedges and wall ſides, and many other untilled places, yet they will alſo be found in many gardens, where if they be ſuffered or neglected but a while, it ſhall be hard to rid them out againe.

The Time.

They flower and ſeede in the end of Sommer, and the leſſer is ſo plentifully that it will ſeede and ſhed, and ſpring, and ſeede againe, that is, beare ripe ſeed twiſe in one yeare.

The Names.

It is called in Greeke ἀκαλυφη *Acalyphe, quia tacta aſpera & injucunda eſt*, and κνίδη, *quod vellicet & punget, a verbo* κνίζειν *quod vellicare & pungere ſignificat*, in Latine *Urtica, ab urendo quod pruritum puſtulaſque igni ſimiles excitet.* The *Arabians* call it *Humiuro, Vraith latum Angiara. Tragus* ſaith *Serapio* calleth it *Hamure Vraith*, and the ſeede of it *Bezori Bangora ſeu Ragi.* The *Italians Ortica*, the *Spaniards Ortiga*, the *French Ortie*, the *Germanes Neſſell*, the *Dutch* men *Netteles*, and we in *Engliſh* Nettle. The firſt is called *Urtica Italica* of ſome, and *hortenſis*, and is the firſt kinde of *Dioſcorides*, called of *Cluſius Legitima*, of moſt writers *Romana* and *mas* or *maſcula*; for the ſecond is called *famina*, and of moſt authors *Vrtica major*, and *vulgaris* or *urens*. The third is called by *Tragus*, *Urtica vulgaris urens altera*, and of *Lugdunenſis Urtica Olygophyllos a paucitate foliorum.* The fourth is called *Urtica minor* of all writers, but onely of *Cæſalpinus exigua*, and of *Dodonæus urens minima*, and is the third of *Tragus*, *Matthiolus*, *Lugdunenſis*, and *Caſtor Durantes*: it is the *Cania* of *Pliny*, which *Cornarius* thinketh ſhould be rather written *Canina*.

The Vertues.

Although Nettles doe hurt and ſting the skinne and fleſh, while they are greene, which is cauſed by the haire or rough downe upon them, and might be thought to be cauſticke or exulcerating being otherwiſe applyed, yet it is not ſo, being found to be hot and dry in the ſecond degree; the leaves boyled in wine and drunke, is ſaid to open the belly and make it ſoluble: the rootes or leaves boyled, or the juice of either of them, or both, made into an *Electuary* with Honey or Sugar, is a ſafe or ſure medicine to open the pipes and paſſages of the Lungs, which is the cauſe of wheeſings and ſhortneſſe of breath, and helpeth to expectorate tough cold flegme ſticking in them, or in the cheſt or ſtomacke, as alſo to raiſe the impoſtumated Plureſie, and ſpend it by ſpitting: the ſame alſo helpeth the Almonds of the throate when they are ſwelled, to gargle the mouth and throate therewith, the juice alſo is effectuall to ſettle the pallate of the mouth in its place, and to heale and temper the inflammations and ſoreneſſe of the mouth and throate: the decoction of the leaves in wine and drunke, is ſingular good to provoke womens courſes, and to ſettle the ſuffocation or ſtrangling of the mother, and all other the diſeaſes thereof, as alſo applyed outwardly with a little Myrrhe: the ſame alſo or the ſeed provoketh urine, and expelleth gravell and the ſtone in the reines or bladder; often prooved to be effectuall in many that have taken it; the ſame decoction alſo of the leaves or ſeede, or being beaten and drunke in that decoction, killeth the wormes in the bellies of Children, and is ſaid to eaſe the paines in the ſides, and to diſſolve or breake the windineſſe in the ſpleene, as alſo in the body; but others doe thinke that it being ſomewhat windy of it ſelfe, is not ſo powerfull or availeable to expell wind, but onely to provoke Venery; the juice of the leaves taken two or three dayes together, ſtayeth bleeding at the mouth, which riſeth from the ſtomacke: the ſeed being drunke is a remedy againſt the ſtinging of venemous creatures, the bitings of madde dogs, the poyſonfull qualities of Hemlocke, Henbane, Nightſhade, Mandrake, or other ſuch like herbes, that ſtupify and dull the ſenſes, as alſo the Lethargy, but eſpecially to uſe it outwardly to rubbe the forehead and temples in the Lethargy, and the places bitten or ſtunge with beaſts, uſed with a little ſalt, *Nicander* ſaith, it helpeth them that have taken Quickſilver, and thoſe that have eaten evill Muſhromes, or ſurfet of the good; the diſtilled water of the herbe is very effectuall, (although not ſo powerfull,) as well for all the diſeaſes aforeſaid, as for outward wounds, and ſores, to waſh them, and to clenſe the skinne from Morphew, Lepry, and other diſcolourings thereof; the ſeede (and ſome alſo uſe the leaves) being bruiſed, and put into the noſtrils, doth ſtanch the bleeding of them, and taketh away the fleſh growing in them, called *Polypus*: the juice of the leaves or the decoction of them or of the rootes, is ſingular good to waſh either old rotten and ſtinking ſores, or fiſtulaies and Gangrenes alſo, and ſuch as are fretting eating or corroding ſcabbes, alſo mangineſſe and itches in any part of the body, as alſo greene wounds, by waſhing them therewith, or putting the juice into the ſores or wounds, or applying the greene herbe bruiſed thereunto, yea although the fleſh were ſeparated from the bones; the ſame alſo applyed to overwearied members refreſheth them, or to places out of joynt, after the joynt is ſet in its right place, it ſtrengtheneth, dryeth, and comforteth them, as alſo to thoſe places troubled with aches and goutes, and the defluction of humours upon the joynts or ſinewes, it eaſeth the paines, and dryeth or diſcuſſeth the defluctions: an ointment made with the juice, oyle and a little waxe, is ſingular good to rubbe cold and benummed members, to bring them to their proper activity againe; a handfull of the greene leaves of Nettles, and another of Wall-wort or Dane-wort, bruiſed and applyed ſimply of themſelves to the Gout, Sciatica, or joynt aches, in any part, hath beene found to be an admirable helpe thereunto: it is ſaid that if greene Nettles be put into the urine of a ſicke body, if it be freſh and greene, after it hath lyen foure and twenty houres therein, the party ſhall recover of that ſickneſſe, but if it doe not abide greene, it ſignifieth death or great danger; if you give hennes ſome dry Nettles broken ſmall, with their meate in winter, it will make them lay egges all the winter more plentifully; it is ſaid alſo, that if the herbe be rubbed on the privities of female beaſts, that will not ſuffer the males to cover them, it will cauſe them the more willingly to ſuffer them to doe it: the oyle of roſes or ſallet oyle boyled with the juice, or the juice of the leaves themſelves, is a preſent remedy to take away the ſtinging of the Nettles: to all the purpoſes aforeſaid, the Romane Nettle is held the moſt effectuall, yet where it cannot be had, the other are in a degree next it, as effectuall, yet the leaſt is thought of ſome to be leſſe powerfull, and of others to be as availeable as any of the other two.

CHAP. XIV.

Polygonum majus. Great Knot-graſſe.

THe Knot-graſſes are divided into two kindes, male and female, of the male kindes I ſhall ſpeake in this and the following Chapters, becauſe they are of many ſorts, ſome greater, others leſſer; and ſome Sea plants, the female being called Sharegraſſe, or Horſetaile, ſhall be entreated of in another place; I thinke it fitteſt therefore to divide theſe into three parts, and ſpeake of the greateſt in this Chapter, of the leſſer kindes in the next, and of thoſe kinds that beare fruite or berryes in another following them, that ſo being orderly ſet downe, every one apart, it might yeeld the more profit to the reader.

1. *Polygonum mas vulgare majus.* The greater common Knot-graſſe.

The greater common Knot-graſſe ſhooteth forth many long ſlender branches full of joynts, lying upon the ground, with divers long and narrow leaves ſet thereon, one for the moſt part at a joynt, having moſt uſually a ſmall white skinne that covereth the joynt; whereat, eſpecially from the middle of the branches upwards come forth the flowers, which are ſo ſmall, that they are for the moſt part not ſeene and diſcerned, which in ſome are white, in others of a whitiſh purple colour, which after turne into very ſmall ſquare ſeed: like unto Sorrell ſeede: the roote is reddiſh, ſmall, ſhort and round, abiding the Winter, and ſhooting a new every yeare. I ſaw in Mr. Dr *Foxes* booke of dryed herbes which he received from *Padoa* a greater ſort hereof, whoſe figure I here give you. *Maximis folijs.*

2. *Polygonum vulgare minus.* The leſſer common Knotgraſſe.

This leſſer Knotgraſſe groweth in all things like the former, and differeth from it onely in the leaves, which are ſmaller, and neither ſo broad or long, and the flowers hereof are alwayes white.

3. *Polygonum minus breviore folio.* Small ſhort leafed Knotgraſſe.

This other ſmall kinde, hath likewiſe many ſlender joynted branches, but more wooddy then the former, ſpread alſo into ſome other ſmaller ones, whereon grow ſmall ſhort leaves, leſſer then thoſe of the ſmall St. *Johns* wort: the flowers are ſmall and white like the other.

4. *Polygonum Saxatile.* Stony Knotgraſſe.

The ſtony Knotgraſſe hath many weake trayling branches full of joynts, riſing from a ſmall white fibrous rootes, lying upon the ground, round about it, whereon grow leaves that are ſomewhat round, being of an inch in length, and halfe an inch in breadth, but growing ſmaller to the ſtalkeward, greene on the upperſide, and of a whitiſh mealy colour underneath, at the joynts come forth ſmall pale reddiſh flowers, like unto the other, and after them followeth ſuch like ſeede as in the other.

1. *Polygonum mas vulgare majus.*
The greater common Knotgraſſe.

Polygonum maximis folijs.
The greateſt Knotgraſſe.

5. *Polygonum*

5. *Polygonum marinum majus.*

The greater Sea Knotgraſſe.

The greater Sea Knotgraſſe, runneth out into many and much larger branches then the firſt, lying on the ground, yet full of joynts, ſet very cloſe together, with leaves thereon, ſomewhat like the common kind, but thicker, ſomewhat ſhorter and broader, and of a darke greene colour above, and whiter underneath: the flowers ſtand at the joynts in the ſame manner, having ſmall white skinnes that cover the joynts, which in ſome alſo are of a white, and in others of a purpliſh colour; after which commeth ſmall ſeede, encloſed in whitiſh ſhining skinnes; the taſte of the whole plant and every part thereof is aſtringent, but ſomewhat ſalt withall: the roote is ſomewhat great, thicke, blacke, long, and ſomewhat wooddy.

6. *Polygonum marinum minus.*

The leſſer Sea Knotgraſſe.

This leſſer kind hath longer ſtalkes then the laſt, covered with a reddiſh barke, and more divided into ſmaller branches, having fewer joynts on the greater ſtalkes, but the branches are thicke, ſet with ſmaller leaves then the former, and are ſomewhat fat and thicke, long and narrow like the common kinde: the flowers are ſmall and whitiſh, and the ſeede is not much unlike the laſt, the roote is ſomewhat long blacke and wooddy, with a few fibres ſet thereat.

5. 6. *Polygonum marinum majus & minus.*
The greater and leſſer Sea Knotgraſſe.

The Place.

The firſt two ſorts grow every where, and in every Country almoſt, both by the footewaies in fields, and on the ſides of highwayes that are greene, for in ſome it overſpreadeth them, and by the ſides of old walls. The third groweth upon the higher grounds, and upon hils and mountaines. The fourth in the ſame places alſo, among the ſtones in the rougher parts. The two laſt grow by the Sea ſide in divers places.

The Time.

They ſpring up late in the Spring, and abide all the Sommer untill Winter, when all their branches periſh.

The Names.

It is called in Greeke πολύγονον *Polygonum, quod multis genubus creſcit*, which name is uſuall to it in Latine, yet it is alſo called *Seminalis, Sanguinalis, Sanguinaria* and *Proſerpinaca* of the ſeverall properties it hath to ſtanch blood, or to creepe on the ground: in the Apothecaries ſhops in *Italy* and many other places *Corrigiola*, and *Centinodia*, for the ſeverall reſpect unto the qualities to correct the heate of the ſtomacke and body, or for the joynts and knots that every branch hath. The *Arabians* call it *Baſia trahagi*, the *Italians Poligono*, *Corregiola*, and ſome *Lengua Paſſerina*. The *Spaniards Corriola*. The *Frenche Renovee*, *Corrigiole*, and of the *Walloones Marjolene de Cure*. The *Germanes Weggraſſe*, and *Wegdrit*. The *Dutchmen weghgras oft duyſent knoop*. In *Engliſh* Knotgraſſe, and Swines graſſe, and in the North Country of divers, Birds tongue, from one of the *Italian* names. The firſt three ſorts are uſually of al authors called *Polygonum mas* or *maſculum*, for they are al alike, differing only that the one is bigger or leſſer then another (for the *Polygonum fœmina* or *fœmineum* differeth in forme very much from this, and ſhall be entreated of among the *Equiſeta*, Sheregraſſes, or Horſetailes, as being likeſt unto them, although not rough:) ſome alſo call the firſt *vulgare* or *majus* for diſtinctions ſake from the ſecond and third, which are both called *minus*; yet the third is thought by *Bauhinus* in his *Pinax*, both to be the *Polygonum maſculum fruticoſum* of *Thalius*, in the deſcription of *Harcynia ſylva*, (which *Camerarius* hath ſet forth and joyned it to his *Hortus Medicus*,) and alſo the *Sedum minimum arboreſcens vermiculatum* of *Lobel*, for he ſeemeth doubtfull unto which *Thalius* his *Polygonum* ſhould be referred. The fourth *Bauhinus* calleth *Polygonum Saxatile*, and no other before him that I know hath made mention of it. The fifth is called *Polygonum marinum* by *Lobel* in his Obſervations, and *Polygonum marinum maximum* in his *Adverſaria*, and of *Lugdunenſis Polygonum marinum primum Dalechampij*, as he calleth the laſt *Polygonum marinum alterum Dalechampij*; which *Bauhinus* calleth *Polygonum maritimum anguſtifolium*, calling the former *Latifolium*.

The Vertues.

The common ſorts of Knotgraſſe are cooling drying, and binding, in ſo much that the juice of them is moſt effectuall to ſtay any bleeding at the mouth, being drunke in ſteeled or red wine, and the bleeding at the noſe to be applyed to the forehead and temples, or to be ſquirted up into the noſtrils; it is alſo no leſſe effectuall to coole and temper the heat of blood, or of the ſtomacke, and to ſtay any flux of the blood or humours, either of the belly, as all laskes or bloody fluxes that come by chollericke and ſharpe humours, or the abundant flowing of womens courſes, or the running of the reines alſo, the juice given before the fit of an ague, be it *tertian* or *quartane* doth come, is ſaid to expell it and drive it away, it is alſo ſingular good to provoke urine when it is ſtopped, as alſo when it paſſeth away by droppes, and with paine, which is called the Strangury, as alſo the heate and ſharpneſſe therein; and to expell powerfully by the urine, the gravell or the ſtone in the reines or bladder, to take a dramme of the powder of the herbe in wine for many daies together; which effects as *Dioſcorides* doth affirme, ſo *Galen* ſeemeth not to deny, but onely ſaith that *Dioſcorides* hath not ſufficiently expreſſed himſelfe in the manner of the diſeaſe and how it ſhould be given: being boyled in wine and drunke, it is profitable to thoſe that are ſtung or bitten by venemous creatures, and the ſame is very effectuall to ſtay all defluxions of rheumaticke humours upon the ſtomacke, and killeth likewiſe the wormes in the belly or ſtomacke, and quieteth all the inward

paines

paines of the body, either in the ſtomacke or belly or other parts that ariſe from the heate, ſharpeneſſe and corruption of bloud and choller: the diſtilled water hereof taken by it ſelfe, or with the powder of the herbe or ſeede, is very effectuall to all the purpoſes aforeſaid: the ſaid water or the juyce of the herbe, is accounted as one of the moſt ſoveraine remedies to coole all manner of inflammations, even Saint *Anthonies* fire, or any other breaking forth of heate, all hot ſwellings and empoſtumations, all gangrenous, that is eating and fretting or burning ſores and fiſtulous cancers, or foule filthy ulcers being applied or put into them, but eſpecially for all ſorts of ulcers and ſores happening in the privy parts of men or women, reſtraining the humours from falling to them, and cooling and drying up the hot and moiſt inflammations, that are apt to follow ſuch ſores in ſuch places: it no leſſe helpeth all freſh and greene wounds, by reſtraining the bloud, and quickly conſolidating the lippes of them: the juyce dropped into the eares helpeth them wonderfully, although they are foule, and have running matter in them: the ſea kindes of Knotgraſſe, are not thought to be ſo cooling and operative for the griefes aforeſaid, in regard they have gotten more heate by their ſalt habitation; yet effectuall in many of the other properties, the ſalt qualitie cauſing ſomewhat the more penetration.

CHAP. XV.

Polygona minora. Divers ſorts of ſmall Knotgraſſe.

OF theſe ſmaller kindes, there are many more than of the former, differing the one from the other, as ſhall be declared hereafter: and firſt I will ſhew you thoſe that come neareſt in outward face and forme unto the other, next going before, and the ſmalleſt afterward.

1. *Polygonum montanum niveum.* White Mountaine Knotgraſſe.

This Mountaine Knotgraſſe is ſo fine a white ſilverlike plant, eſpecially in the hotter countries, and when it is growne old, that it giveth much delight to the beholders of it: for it ſpreadeth many weake trayling branches upon the ground, in ſome places not paſt an hands breadth, in others a foote long, as full or fuller of joynts than any of the former, and thicke ſet alſo with ſmaller branches; whereon are placed very ſmall long leaves, lying almoſt like ſcales upon the whitiſh hard ſtalkes, theſe leaves are greene at the firſt and tender, but when they are growne old, they will be of a ſhining ſilver colour, and hard like skinnes or parchment, the toppes of the ſtalkes and branches being thicke ſet, with ſmall white ſilver-like leaves: and at the joints alſo come forth very ſmall white flowers ſcarſe to be diſcerned, where alſo afterward there is the like ſeede, but ſmaller; the roote is ſmall long and white, not periſhing neither the branches nor the leaves in the Winter in his naturall place, but will not endure our cold blaſtes and nights, and therefore periſheth unleſſe it have more eſpeciall care and proviſion to preſerve it.

1. *Polygonum montanum niveum.*
White Mountaine Knotgraſſe.

2. *Polygonum montanum Vermiculatæ foliis.*
Mountaine Knotgraſſe with Stonecrop leaves.

This ſmall herbe (or Knotgraſſe for unto this family *Bauhinus* doth referre it) groweth not much more than an hand breadth high, ſending forth many ſlender whitiſh round ſtalkes full of joynts which doe a little bend themſelves downe againe to the ground; at the joynts are ſet ſmall long round fat leaves like unto thoſe of Stonecrop pointed but not pricking at the ends, and with the leaves; at the ſaid joynts towards the toppes riſe ſingle flowers, that is one at a joynt ſomewhat large that it doth ſeeme many, of a greeniſh colour, laid open like a Star, with divers whitiſh ſmall threds in the middle ſcarſe to be diſcerned, after which commeth a ſmall round ſeed veſſell and ſmall ſeede therein: the roote is ſmall white and threddy; this hath neither taſte nor ſent much to be perceived therein, onely it is a little harſh and drying and ſomewhat bitter withall: it ſeemeth to partake in face with the Stonecroppes, and in taſte, with Knotgraſſe, and the title riſeth from both.

3. *Polygonum Valentinum ſive Anthyllis Valentina Cluſij.* *Spaniſh* Knotgraſſe.

This ſmall plant which *Cluſius* found in *Spaine*, and thought might be referred to the *Anthyllides*, is by divers the beſt Herbariſts ſince, accounted a kinde of Knotgraſſe, or more neerely reſembling them, for it ſhooteth forth many ſmall weake reddiſh branches, lying upon the ground, and not able to ſtand upright, about a foote long, parted into many other ſmaller branches, whereon grow at ſeverall joynts and ſpaces many ſmall leaves together, like unto thoſe of Time ſpurge; whereon, as well as on the ſtalke there groweth a ſhew of mealineſſe, as many ſea plants have; with the leaves come forth ſmall purpliſh white flowers, conſiſting of foure leaves apeece; the ſeede hath not beene obſerved: the roote is ſmall long and blackiſh on the outſide.

4. *Polygonum minus Monſpelienſe.* Small knotgraſſe of *Mompelier.*

This ſmall *French* Knotgraſſe hath divers ſmall branches lying upon the ground, full of joints, whereat are ſet ſmall greene leaves, being ſomewhat round and like unto thoſe of the ſmall Lentilles: the flowers are very ſmall and of a whitiſh colour, tending unto greene, ſtanding at the toppes of the branches onely, and many ſet there together, which afterwards give very ſmall ſeede: the roote is ſmall, but very long, growing downe deepe into the ground: this plant is very like *Cluſius* his *Anthyllis Valentina*; but *Bauhinus* conteſteth ſeriouſly againg them that would ſo take it; for that *Cluſius* his *Anthyllis* hath reddiſh branches, and this hath greene, his hath much ſmaller leaves, and more ſtore of flowers, and that of a purpliſh colour, and none at all ſtanding at the toppes of the branches: all which conſidered, he determineth that this is a differing ſort from the other.

2. *Polygonum montanum Vermiculatæ foliis.* Mountaine Knotgraſſe with Stonecrop leeves.

5. *Polygonum Creticum Thymi folio.* *Candy* Knotgraſſe.

This ſmall *Candy* Knotgraſſe lieth likewiſe with his ſmall branches upon the ground, not paſt an hand breadth in length: the leaves ſtand at the joints, ſometimes but one or two, and ſometimes three or foure, differing in bigneſſe and length one from another; with the leaves ſtand alſo many ſmall white flowers together, as it were in a knot or bunch: after which commeth the ſeede, which is ſmall and plentifull.

6. *Polygonum Serpylli folio Lobelij.* *Lobels* Knotgraſſe with Mother of Time leaves.

This Knotgraſſe that *Lobel* hath ſet forth in his *Adverſaria*, hath very long threddy ſtalkes ſpread upon the ground, branched forth in divers places, with many ſmall long and round leaves ſappie or full of juyce, ſomewhat like unto Stonecroppe, ſet together at the joints: the whole plant ſomewhat reſembleth *Serpyllum Narbonenſe*, *French* mother of Time: the roote is long and woodie, of a bitteriſh taſte, ſomewhat hot upon the tongue.

3. *Polygonum Valentinum.* *Spaniſh* Knotgraſſe.

7. *Polygonum Germanicum ſive Knawell Germanorum.* *Germane* Knotgraſſe or Knawell.

The *Germanes* Knawell ſendeth forth from a ſmall ſlender threddy roote, divers ſmall branches, not fully lying downe on the ground, halfe a foote long full of joints, thickly ſet together, at every one whereof, ſtand many very ſmall and long pointed leaves, of a grayiſh greene or aſh colour, which are of an unequall length, two for the moſt part longer than the other: at theſe joynts with the leaves grow out divers ſmall herby or greene Starre-like flowers, thicke ſet together, which being fallen there appeare very ſmall huskes, no bigger than Millet ſeede, great ſtore of very ſmall ſeede, like duſt, or the ſeede of *Herniaria* Rupturewort, which are of a quicke hot ſent, ſomewhat ſweete.

8. *Polygonum alterum Germanicum.* Another *Germane* Knotgraſſe.

This other Knotgraſſe of *Germany*, doth very much reſemble the former, both in the manner of the growing, with ſlender trailing branches, and ſmall long hoary, or grayiſh greene leaves, many ſet together at a joint, but that they are longer than they, ſome of them two inches long, eſpecially thoſe next the roote: the flowers hereof ſtand not at the joints with the leaves, but at the toppes of the ſtalkes and branches, many cluſtering together which are very ſmall and white on the inſide, but of a browniſh red colour on the outſide, which after turne into very ſmall ſeede, and in a plentifull manner: the roote is ſmall long, and white.

9. *Millegrana major ſive Herniaria vulgaris.* Rupturewort.

The Rupturewort ſpreadeth very many threddy branches, round about upon the ground, about a ſpanne long, divided into many other ſmaller parts, full of ſmall joints, ſet very thicke together, whereat come forth two verie ſmall leaves, of a freſh yellowiſh greene colour, branches and all, where at grow forth likewiſe a number of exceeding ſmall yellowiſh flowers, ſcarſely to be diſcerned from the ſtalkes and leaves, which turne into ſeede as ſmall as the very duſt: the roote is very long and ſmall, thruſting downe deepe into the ground: this hath neither ſmell nor taſte at the firſt, but afterwards it hath a little ſtiptive or aſtringent taſte, without any manifeſt heate, yet a little bitter and ſharpe withall.

10. *Herniaria major Africana.* The greater Rupturewort of *Africa.*

This *African* kinde groweth greater, larger, and more upright than the laſt, and fuller of beanches, in other things little differing.

11. *Millegrana*

11. *Millegrana minima ſive Herniaria minor.*
Rupturewort with longer leaves.

This other kinde of Rupturewort, hath likewiſe ſmall threddie ſtalkes, but with fewer joints, and long narrow leaves, ſomewhat rough or hairy ſet at them, fuller of branches towards the toppes, where the flowers and ſeede doe grow like unto the other, and in a plentifull manner alſo: the roote is ſmall but not ſo long. *Bauhinus* maketh mention in his *Pinax* of one which he calleth *fruticoſa* with wooddie low ſtalkes, and ſome long leaves growing thicke thereon.

The Place.

The firſt groweth both about *Arles* and *Marſeilles* in *France*, and in *Valentia*, *Marcia*, and *Salamanca* in *Spaine*, as *Cluſius* and *Pena* doe record: the ſecond in *Naples* as *Columna* ſaith: the third *Cluſius* ſaith, groweth likewiſe about the Caſtle of *Valentia* in *Spaine*: the fourth both on the mountaines of *Eſcuriall* in *Spaine*, and in the barren grounds about *Mompelier* in *France*, as *Bauhinus* alſo ſaith: the fift in *Candy*, as *Bauhinus* ſaith, who had the ſeede from thence: the ſixt upon the hills neare the ſea in *Provence* of *France*, as *Pena* alſo ſaith: the ſeventh in the Weſt countrie about *Chipnam*, if *Lobel* his figure be true; and in many places of *Germany* by the wayes ſides; and ſo doth the eight likewiſe in drie ſandy and rockie places: the ninth groweth in many places of our owne Land, as well as in others, in drie barren grounds, where it will be ſmall, and in the moiſter places alſo, but not boggie or moriſh, that are not ſhadowed: the tenth in *Africa* neare *Tunice* where *Guillame Boel* gathered it: the laſt in the drie chalke or ſtony grounds of *Kent*, and other countries.

7. *Polygonum Germanicum ſive Knawell Germanorum.* *Germanè* Knotgraſſe or Knawell.

Fruticoſa.

9. *Herniaria vulgaris.*
Rupturewort.

10. *Herniaria major Africana.*
The greater Rupturewort of *Africa.*

The Time.

They all are freſh and greene in the Summer, and unto the Winter, which cauſeth the moſt of them to withet and drie, and in the meane time they perfect their ſeede.

The Names.

The firſt is called of *Lobel* and *Pena* in their *Adverſaria Polygonum montanum minimum niveum, & ſericeum*, of *Cluſius Paronychia Hiſpanica*; of *Lugdunenſis Polygoni Hiſpanici genus Cluſij*: *Tabermontanus* and *Gerard* call it *Polygonum montanum*; and *Bauhinus Polygonum minus candicans*: the ſecond *Columna* calleth *Vermiculatá montana nova*; and *Bauhinus Polygonum montanum Vermiculatæ foliis*: the third *Cluſius* calleth *Anthyllis Valentina*, becauſe he ſaith *Plaza* and other the learned Phiſitions of the Vniverſitie of *Valentia* in *Spaine* did ſo account and call it; which as he ſaith, although it might be a kind thereof, yet it could not be *Dioſcorides* his fifth *Anthyllis*, becauſe it hath upright ſtalkes, which this hath not; but all other Herbariſts doe account it a kinde of ſmall Knotgraſſe, and ſo have I called it, although ſomewhat differing from him; *Bauhinus* maketh it an *Anthyllis* among his *Anthyllides* and a *Polygonum* alſo among theſe, calling it *Polygonum gramineo folio majus erectum*, which in my opinion is not fitting unto it, in that it neither groweth upright, nor hath ſuch long leaves, that they ſhould reſemble graſſe: the fourth *Bauhinus* in his *Pinax*, maketh to be both his ninth ſmall Knotgraſſe, calling it *Polygonum minus tenuifolium*; and alſo his twelfth by the name of *Polygonum minus lentifolium*; and in both places referreth us to the fourth *Polygonum* deſcribed in his *Prodromus*, whereby he filleth up the number of ſorts without reaſon: the fifth *Bauhinus* ſo calleth, as it is in the title: the ſixt *Lobel* calleth *Polygonum alterum puſillum vermiculata Serpilli*

folio; and *Lugdunenſis*, *Polygonum alterum Serpilli folio*; but *Bauhinus Polygonum maritimum minus folio Serpilli*: the ſeventh *Tragus* accounteth to be a kinde of *Polygonum*, which they of his countrie called *Knawel*; hee alſo thinketh it might be called *Polioarpon* of the abundance of ſeede, and *Polycnemon* of the vertues. *Lugdunenſis* alſo calleth it *Polycarpon*, and *Dodonæus* in his *Pemptades* taketh it to be a *Polygonum exiguum*. *Gerard* calleth it *Pologonum Selinoides ſive Knavel*, wherein hee is deceived many wayes. Firſt, in that he giveth the name *Selinoides* unto *Knawel*, when as his owne deſcription and figure thereof might have plainely convinced that errour in him, in that *Knawel* hath not leaves like *Selinum* or Parſly: ſecondly, that he maketh *Knawel* and Parſly pert to be one, whereas they are two plants; then againe that he thinketh, that *Saxifraga Anglicana* of *Lobel*, which he ſaith he found about *Chipnam* in the Weſt countrie to be Parſly pert, when as *Lobel* and *Pena* their deſcription and figure doth contrary alſo that opinion, although their figure be ſomewhat like, as *Gerard* himſelfe confeſſeth, which he calleth *Selinoides*: againe, that he thinketh the Parſly pert, that was ſhewed by a country Empericke, to Mr. *Bredwell*, was *Knawel*, which as it is likely Mr. *Bredwell* ſhewed him, and yet he could not diſcerne the face of the one herbe from the other; and laſtly he findeth fault with the name Parſly pert, calling it a barbarous word, and would amend it with his owne fine Latine word *Petra pungens*, not underſtanding the true Etymologie of the word being corrupted, as for the moſt part all unuſuall or hard words are to the vulgar ſort, for the uncorrupted word is *Percepierre*, a true *French* word, and ſignifieth the ſame that *Lithontribon* in Greeke, *Saxifraga* in *Latine*, or *Gerard* his *Petra pungens*, if ye like it; Breakeſtone in *Engliſh*, of all which I ſhall ſpeak more fully in the next Chapter: but I have here before given you my opinion of the *Saxifraga Anglicana* of *Lobel*, neither can I thinke the *Knawel* of *Tragus* to be it as many might imagine by the likeneſſe of their figures being compared together; but ſurely it may be a kinde thereof: the forme and ſtrong ſweet ſmell, which *Tragus* ſaith it hath, inducing me in part ſo to thinke, but that the ſmall greene flowers and ſeede in them be much differing from the Pincke-like white flower in that: the eight, I call *Polygonum alterum Germanicum*, another *Germane Knawel*, becauſe it is ſo like thereunto, and that *Bauhinus* ſaith, the *Germane Knawel* hath many varieties, whereof I thinke this to be one, and it is probable alſo, that both the *Polygonum montanum niveum*, and the *Anthyllis Valentina* may be a ſpecies thereof; *Bauhinus* himſelfe calleth it *Polygonum litoreum minus floſculis ſpadiceo albicantibus*: the ninth is called *Empetron* by *Tragus* and *Lonicerus*, but not truely; *Polygonum minus* by *Matthiolus* and *Caſtor Durantes* that followeth him, *Herba Cancri minor* by *Cordus* in his *Scholiaſtes*, and *Millegrana* in his hiſtory of plants, *Epipactis* by *Anguillara*, *Herba Turca* by *Lobel* and *Cæſalpinus*, *Herniaria multigrana Serpylli folio*, by *Pena* in his *Adverſaria*, and generally *Herniaria*, and ſo by *Geſner in hortis Germaniæ*, and *in libello de collectione ſtirpium*, by *Camerarius Dodonæus*, *Thalius*, *Lugdunenſis*, *Tabermontanus*, and *Gerard*, and by *Bauhinus Polygonum minus, ſeu Millegrana major*; the tenth we have impoſed the name as it is in the title and moſt ſuting thereunto: the laſt is called *Millegrana minima* by *Lobel* in his *Dutch* Herball, and in his *Icones ſtirpium*, by *Thalius Herniaria altera*; and therefore I call it *Herniaria minor*, *Bauhinus* calleth it, *Polygonum minimum, ſive Millegrana minima*.

The Vertues.

All or moſt of theſe ſorts of Knotgraſſe, doe participate with the former in the binding qualities, although not altogether ſo much in the cooling, ſome of them having a little bitterneſſe or ſharpeneſſe in them, which declareth ſome heate, and therefore hath not that abundant moiſture, which *Galen* ſaith, is in the former, whereby as he ſaith, they have their cooling qualitie: they ſerve to provoke urine, and helpe to breake and expell the ſtone and gravell by urine, as the others doe, yet wee have not ſo evident teſtimony of the operations of the five firſt ſorts, (howſoever the delicacie of forme in ſome of them doe argue in mans judgement ſome ſingular vertue, which yet doth not alwayes follow, for in many deformed, there is found much more helpe) as we have of the reſt, which are theſe in particular; *Tragus* ſaith that *Knawel* hath the ſame properties that Knotgraſſe hath, and may ſerve in the ſtead thereof to all purpoſes, as well inward as outward remedies, when the other is not at hand, and that it is very powerfull to breake the ſtone, being boyled in wine and drunke, which our owne people doe averre alſo: the other *Germane Knawel* or Knotgraſſe being of the ſame kinde, worketh the like effects. Rupturewort hath not his name in vaine, for it is found by daily experience in a number that have taken it, to helpe and cure the rupture, not onely in children, but in elder perſons, ſo as it be not too old and inveterate; by taking either a dramme of the powder of the dried herbe, every day in wine for certaine dayes together, as the ſtrength of the diſeaſe and age of the patient doe require; or the decoction made of the herbe in wine and drunke, or the juice or diſtilled water of the greene herbe taken in the ſame manner; and helpeth all other fluxes, either of men or women, vomitings alſo and the Gonorrhea, being taken any of thoſe wayes aforeſaid; it doth moſt aſſuredly helpe alſo thoſe that have the ſtrangurie, and have their urine ſtopped, or are troubled with the ſtone or gravell in their reines or bladder, cauſing them that take it to urine plentifully, and thereby to remove and waſh downe, whatſoever ſticketh or is offenſive in the paſſages thereof: *Vide Hollerium de morbis internis, lib.* 1. *c* 62. *fol.* 268. the ſame alſo helpeth much all ſtitches in the ſides, all griping paines or torments in the ſtomacke or belly, cauſed by collericke or ſharpe or ſalt humours; it helpeth the obſtructions of the liver, and cureth the yellow jaundiſe likewiſe; it killeth alſo the wormes in children: being outwardly applied it conglutinateth wounds very notably, and helpeth much to ſtay defluxions of rheume from the head to the eyes, noſe or teeth, being bruiſed greene and bound thereto, or the decoction of the dried herbe, to bathe the forehead and temples, or the nape of the necke behinde, it doth alſo drie up the moiſture of fiſtulous ulcers, or any others, that by the much acceſſe of ſharpe humors are growne foule and ſpreading: the leſſer Rupturewort is not much wanting, in all the faculties of the other.

CHAP. XVI.

Polygonum Selinoides. Parſly pert, or Parſly Breakeſtone.

HAve as you ſee ſeparated this kinde of Knotgraſſe from all the other in the laſt Chapter, and not without juſt reaſon as I take it, becauſe the face and forme thereof, is ſo much differing from them, as the enſuing deſcription will declare: the roote is very ſmall and threddy, but abiding divers yeares in the naturall places, from whence come many leaves, ſpread upon the ground, each ſtanding on a ſmall long foote ſtalke

ſtalke, and being as broad as the naile of a mans finger or thumbe, is very much jagged on the edges, making it ſeeme ſomewhat like unto a Parſlye leafe, whereof came the name, but of an overworne or dusky greene colour: from among which riſeth up weake and ſlender ſtalkes about three or foure fingers long, ſet full of the like leaves but ſmaller up to the toppes, that almoſt no part of the ſtalkes can be ſeene, and all for the moſt part ſtanding cloſe thereunto, few of them having any footeſtalke at all, or very ſhort: among theſe leaves come forth very ſmall greeniſh yellow flowers, ſcarſe to be diſcerned, where afterwards groweth the ſeede, as ſmall as any of the former.

Sive Percepierre Anglorum Polygonum Selinoides.
Parſly pert, or Parſly breakeſtone.

The Place.

This groweth naturally in moſt countries of this land, if it be obſerved by any that have skill, but eſpecially in ſuch barren and ſandy grounds as doe not want moiſture, for it joyeth much more in the wet places then in the dry, I found it upon *Hampſteed* Heath by the foote pathes, where being a dry ground, and in a dry time, it was very ſmall, which elſe in a moiſter time, and in a moiſter place upon the ſame Heath, was much greater, as alſo neare unto the meereſtones by *Lambeth*, which divide the liberties of *London* from *Surrey*.

The Time.

It is to be found all times of the Sommer, Spring, and Harveſt, even from *Aprill* unto the end of *October*, in ſeverall places, for in the open and Sunny places it will be withered, when in the ſhadowy and moiſt it will continue.

The Names.

This plant (being of long continuance in our land and knowledge to us, by the properties, for it hath not beene mentioned, by any the moſt curious ſearchers and writers of herbs beyond ſea, as being onely peculiar I thinke to our Country, before *Lobel* came to us, who called it *Percepierre Anglorum* and *Lugdunenſis* from him) hath received no Latine name at all, and therefore I have transferred the name *Polygonum Selinoides* hereunto, as more proper unto it, then *Gerards* Knawell is unto it; for it may moſt fitly be reckoned a *Polygonum*, by the manner of the growing, and the name *Selinoides* may moſt fitly agree unto it from the forme of the leaves, being derived from the Greeke word *Selinon*, for *Knawel* hath no likeneſſe with *Selinum* Parſly. In the former Chapter, I ſhewed you *Gerard* his errours herein, now let me ſhew you mine alſo (if peradventure I ſpeake not *per Antiphraſim*) concerning theſe names of *Percepier* or *Perch pier*, as ſome call it, and Parſly pert, or Parſly breakeſtone, as they are uſually called in *Engliſh*; I ſhewed you before that the word Parſly pert, was but a corruption of time in the vulgar ſort, and *Percepier* alſo, derived from the *French* word *Percepierre*, which as I ſaid before, ſignifieth as much as *Lithontribon* in *Greeke*, *Saxifraga*, *Petriſindula* an old outworne word, and *calculum frangens* in Latine, pierce ſtone, or breakeſtone in *Engliſh*; ſome call it Parſly pert and derive it from *petra*: but the more proper Engliſh is Parſly breakeſtone. Now concerning this and *Lobel* his *Saxifraga Anglicana*, both of them are affirmed by *Lobel* to grow in the Weſt Country, and both are uſed for one purpoſe, (yet *Lobel* ſeemeth to referre the *Percepier* unto the *Cerefolium*, & *Scandix ſive Pecten Veneris*, or partaking of both of them, but moſt unproperly in my minde, which hath cauſed *Bauhinus* in his *Pinax*, following his opinion to make it a ſpecies of *Cerefolium*, calling it *Chærophyllo nonnihil ſimilis planta*, and *Tabermontanus* thereupon calleth it *Scandix minor*; and *Columna* was alſo much deceived in thinking this to be an *Alchymilla*, calling it *minima montana*.

The Vertues.

This herbe hath properly with the vulgar ſort, both men and women leeches, who have had moſt practice of it, not found any other operation then to helpe to provoke urine, and breake the ſtone in thoſe that are troubled therewith, for which purpoſes it is moſt availeable; for they uſe to eate it familiarly as a Sallet herbe, and pickle it up as a *Sampire* to eate in winter, but is uſed alſo more Phyſically, either by it ſelfe or with other things, and either in powder or in juice, decoction or water diſtilled from it; whoſe ſeverall wayes, that I may declare them a little more amply are theſe. Take of the juice of the herbe about three ounces, put this with ſo much white wine, as is fit to make a poſſet, take hereof every morning and evening a draught, or ye may adde hereto Wild Time, or Mother of Time, and ſome Camomill: You may alſo boyle theſe herbes aforeſaid, in white wine, or in water if wine be not at hand, and drinke it when it is ſtrayned in the ſame manner, the powder alſo of the dryed herbe, to the quantity of a dramme or leſſe, in white wine, or in other drinke where wine is wanting, for divers dayes firſt and laſt, and the diſtilled water of the herbe taken with a little Sugar in the ſame manner, is found to be a ſingular remedy to provoke urine, when it is ſtopped wholly, or paſſeth away by drops with paine, or unſenſibly without paine, expelleth ſtore of gravell in thoſe that breede it, and the ſtone alſo in the reines or kidneyes, in waſhing it downe by the aboundant paſſage of the urine, and helpeth alſo to expulſe it out of the bladder, if it be not growne too great for the paſſages; otherwiſe it is held very probable, that the aboundance of urine brought downe into the bladder by the vertue of the medicine, and there abiding, worketh ſo much upon the ſtone, therein confirmed and growne great, that it waſteth it by degrees, avoyding it in gravell with the urine. If you will have the receipt of the Country *Empericke* given to Mr. *Bredwell*, a Chirurgion of *London*, who practiſed phyſicke in *London* where he dwelt, as well as in all the Countries where he travelled, it is this. Take of the dryed herbes of Parſly *pert*, and Mouſeare, Bayberries, Turmericke, and Cloves, the ſeeds of the Burre Docke, the ſeede in the heppe or Bryer berries, and the ſeedes of Fenugreeke of each one ounce;

of the ſtone in an Oxes gall twenty foure graines weight; let all theſe be beaten into fine powder and kept by you, in a dry box, or pot, to uſe upon occaſion: whereof the quantity to be taken at a time, is from halfe a dramme to a dramme, as the age and neceſſity of the party, who is to take it ſhall require: but aſſuredly it would worke as effectually in other diſeaſes, either inward or outward, as either the Knotgraſſes, or Knawell, or Rupture-wort doe, if it were ſeriouſly applyed, for being alike in the temperature of the qualities, and working the ſame effects in ſome of the diſeaſes, why not in many of the other, whereunto they are tryed to doe good: I may here deplore the careleſſe courſe of many that are learned, who are content onely to ſucke the hony that other Bees before them have gathered, but make none for others, whereas if they would be induſtrious, they might by their good judgement apply things to much better effect then the bold, blind bayards of our time, who dare to doe any thing, eſpecially when under colour of giving Phyſicke to their pockie patients, they may paſſe without impunity, and without controll.

CHAP. XVII.

Polygona. Baccifera. Berry bearing Knotgraſſe.

THere remaineth of all the ſorts of Knotgraſſes, to ſpeake of thoſe that beare berries, ſome whereof are ſhrubby plants, whoſe berries are their fruite, bearing ſeede within them, whereby they are propagated: others are the excreſſences of the herbe, accidentall onely as I ſuppoſe to the ſoyle, that breedeth them, being not the naturall ſeede, whereof I entend to ſpeake firſt, becauſe it commeth neereſt unto ſome of the former ſmall Knotgraſſes.

1. *Polygonum cocciferum Polonicum,* The Polonian Scarlet Knotgraſſe.

The Scarlet Knotgraſſe is as ſmall a plant as the Knawell, or white mountaine Knotgraſſe, ſpreading in the ſame manner with ſundry ſmall ſtalkes, full of joynts, whereat are ſet divers very ſmall and long leaves, pointed, but not ſharpe at the endes, which with the ſtalkes are of a grayiſh aſhcolour, or more whitiſh, at the toppes of the ſtalkes ſtand a number of ſmall white flowers, yet not ſo ſmall as in the mountaine kinde of Knawell, but ſuch as may be better deſcerned, comming forth of grayiſh greene huskes, wherein after they are paſt, groweth the ſeede, which is as ſmall as duſt, the roote is ſmall and ſomewhat long, at the toppe whereof, and on the ſtalkes next thereunto groweth very ſmall berries, leſſer then thoſe of the *Ilex Coccigera*, or Scarlet Oake, but of as orient a ſcarlet colour as they, and give as precious a dye as they doe, and but that it cannot be had in that quantity (every roote, yeelding but a few berries in compariſon of the other) it would leſſen the price, if not abate the uſe of the other; but howſoever it ſerveth that Country of *Polonia*, in ſome meaſure, to dye ſome of the cloathes that they weare. *Æmatus Luſitanus* in his Commentaries upon *Dioſcorides*, *folio* 623. ſaith that

1. *Polygonum cocciferum Polonicum.* Polonian Scarlet Knotgraſſe.

3. *Polygonum bacciferum ſive Vua marina major.* The greater Sea grape.

theſe

theſe berries grow at the rootes of a kind of Saxifrage like unto Burnet or Burnet Saxifrage, as alſo at the rootes of Cotlsfoote, Pelletory of the Wall, and other herbes likewiſe, and that not onely in *Poland* but in *Italy* and other Countries.

2. *Ephedra ſive Anabaſis.* Climing Knotgraſſe or Sea Grape.

This kinde of Sea Grape groweth in the warme Countries where it is naturall, into a thicke trunke or ſtemme as bigge as a mans arme at the bottome; from whence riſe many very long branches, full of joynts like unto the other Sea grapes, climing up to the toppes of the higheſt plane trees, or others againſt which it groweth, otherwiſe if it ſtand neare unto a lower tree or ſhrubbe, it ſeldome riſeth above their height, yet hath it no claſpers to winde about any thing, nor doe the branches winde themſelves, as the nature of *Apocynum* or *Periploca* Dogs bane doth; yet as the Ivy by ſending forth rootes at the joynts, into the barke of the trees that groweth next thereunto, it thereby climeth unto the toppe of them: at theſe joynts grow no leaves for it is wholly deſtitute of them, but from them ſhoote forth divers other branches, and at the ſame joynts upwards, ſtand many ſmall moſſy flowers, of a pale or whitiſh yellow colour, ſomewhat like unto the bloſſomes of the male Cornell tree, which afterwards turne into ſmall red berries when they are ripe, like unto ſmall Mulberries, full of juice, of a ſowre taſte, wherein lye ſmall yellow ſeede like Millet, the roote ſpreadeth divers wayes under ground, being hard and wooddy.

4. *Vva marina minor.*
The leſſer Sea Grape.

3. *Polygonum bacciferum ſive Vva marina major.*
The greater Sea Grape.

This greater Sea Grape is ſo like unto the former, except in the long and climing branches, that it is verily thought of divers to be but the ſame, not growing neare any ſhrubbe or tree to cauſe it to aſcend as the other doth, and as it is ſaid before that the ſame kinde uſeth to doe, by the report of *Bellonius*, in his third booke of Obſervations, and the 41. Chapter, for this alſo hath a ſtubbed ſtocke, from whence riſe many ſlender branches about a foote long, ſet with joynts like unto an Horſetayle graſſe, up to the toppes, which doe a little bow or hang downe againe, altogether without leaves, and with many moſſy pale flowers, but *Anguilara* ſaith reddiſh ſet together at the joynts, which afterwards turne into ſmall red berries like *Raſpis*, of a ſowriſh taſte, as the other doth, wherein lie the like yellowiſh ſeede: the roote is likewiſe hard and wooddy.

4. *Polygonum bacciferum minus, ſive Vva marina minor.* The leſſer Sea Grape.

The ſmaller Sea Grape riſeth up immediately from the roote, with many ſlender weake, reddiſh, ruſh like ſtalkes, ſixe or ſeaven foote long ſometimes, lying for the moſt part upon the ground, wooddy at the bottome of them, with the like joynts and branches iſſuing from them, as in the former, and without any leaves at them alſo; the flowers are many and pale alſo, and moſſy like them, but ſtanding upon ſomewhat longer footeſtalkes, and the red berries are likewiſe like unto *Raſpis* or Mulberries, of a ſowriſh taſte, wherein is contained a ſmall blackiſh three ſquare ſeede or two, like unto the former: the ſtalkes and branches are no leſſe aſtringent in taſte then the laſt, the roote is ſmaller, and ſendeth forth divers ſuckers, which creeping under ground ſpreade farre.

The Place.

The firſt groweth in many dry, barren, and ſandy grounds, in *Polonia*. The ſecond *Bellonius* in his third booke and 41. Chapter of his Obſervations, ſaith groweth in the valleies or lower plaine grounds, at the foote of the mountaine *Olympus*, and in *Illyricum* betweene *Eaſtello novo*, and the old *Epidourus*. The third *Cluſius* ſaith he found onely in *Spaine*, in the Kingdome of *Murcia*, by the Sea ſide, and no where elſe. The fourth *Lobel* ſaith groweth not onely neare the Sea ſide, about *Cape de Sete*, *Per aul* and *Magulona* not farre from *Mompelier*, but at *Rochell*, alſo about the Sea ſide, and in other places, but *Cluſius* ſaith, he found it not farre from *Salamanca*, which is the heart of *Spaine* in great plenty upon a ſmall hill, whereof he wondreth much, not having found it or hearing of any other to have found it, in any other places then the Sea coaſts. *Anguillara* ſaith in *Dalmatia*, about the river *Sabenicus*.

The Time.

Theſe flower late, and ripen their fruite in the naturall places ſeldome before *October*, and never in theſe colder climates, as hath beene often prooved true: yea the rootes will hardly without eſpeciall care and keeping, be preſerved in the Winter with us.

The Names.

The firſt is mentioned of *Camerarius*, by the name of *Polygonum cocciferum Polonicum* in his Epitome of *Matthiolus*, and as I ſaid before by *Ælmatus Luſitanus*, yet as not growing on *Polygonum* but other herbes. The ſecond is recorded by *Bellonius* in his third booke and 41. Chapter, *fol.* 197. by the name of *Ephedra*, that was full of red ſeede like unto *Androſace*, by *Dodonæus*, under the name of *Ephedra ſive Anabaſis*, as alſo by *Rauwolfius*. *Pliny* calleth it *Caucon ſive Ephedra*. *Bauhinus* calleth it *Polygonum bacciferum ſcandens*. The third is called by *Cluſius* *Polygonum quartum Plinij majus*, and ſaith the *Spaniards* call it *Belcho*: by *Tabermontanus* *Polygonum minimum ſive cocciferum primum*: by *Bauhinus* *Polygonum bacciferum maritimum majus, ſive Uva maritima major*. The fourth is called by *Cluſius* *Polygonum, quartum Plinij minus* who thinketh it to be the *Androſace* of *Bellonius* but I thinke *Bellonius* rather meant the greater ſorts, by *Lobel Uva marina Monſpelienſium*, and conteſteth with *Matthiolus*; (why this ſhould not be *Tragon* or *Traganon* of *Dioſcorides*, (as they of *Mompelier* formerly called it, and afterwards *Androſace* as *Bellonius* did) in that he made *Theophraſtus* his *Scorpio* to be *Tragos*; by *Ruellius Tragos*, by *Lugdunenſis Tragus*, *ſive Scorpius maritimus Dalechampij*, yet in another place he calleth it *Equiſetum quartum*, as *Pena* doth *Equiſeti facie racemoſa planta*; by *Anguillara* it is thought to be *Croton* of *Nicander*, by *Camerarius Tragum* and *Uva marina*, by *Geſner* in *hortis Germaniæ Tragium*, by *Tabermontanus* *Polygonum marinum ſecundum*, and by *Bauhinus* *Polygonum bacciferum maritimum minus*. *Lugdunenſis* taketh it to be *Oſteocollum Hieroclis & Abſirti*.

Abſirti. The *French* call it *Rayſins de mer*, from whence came the name of *Vva marina*.

The Vertues.

The *Polonians* with whom the firſt groweth, doe uſe the herbe in the ſame manner that the *Germans* doe their *Knawel*, that is to expell urine and to breake the ſtone: the ſecond is not knowne, whether the people where it groweth doe uſe it as the two laſt ſorts are, which may well perſwade us, is of the ſame operation, being ſo like in the outward face and forme; for the Sea-grapes are both of one qualitie, and ſerve for the ſame diſeaſes that the Knotgraſſes are uſed by the *Spaniards* where they grow, as *Cluſius* ſaith, but eſpecially to cure the ulcers of the privy parts in men or women: they are alſo very effectuall to provoke urine plentfully, and are exceeding aſtringent and drying, ſo that they powerfully ſtay all fluxes of the belly, or of womens courſes, reſtraine vomitings of the ſtomacke, and the defluxions of thinne rheume from the head: they are alſo very conſolidative to ſoder together the lippes of greene wounds, or to knit broken bones, and to ſettle and ſtrengthen thoſe that have beene out of joint: it is held to be ſo powerfull to knit diſſevered parts, that being boyled with peeces of fleſh, or with other things, it will cauſe them to be ſo glued or ſodered together, that one cannot pull them in ſunder againe; in all ſorts of ruptures alſo, it is moſt effectuall.

CHAP. XVIII.

Caſſia Poetica Monſpelienſium. The red berried Shrubbe Caſſia.

I Have been bold to inſert this plant in this place, becauſe ſome have made it a kind of *Polygonum*, and although we cannot find it to be a Saxifrage or breakeſtone, yet it hath the other drying & aſtringent qualities of *Polygonum*. This ſhrubbe riſeth up to the height of two foote or there abouts, ſpreading many ſlender twiggie greene branches, whereon grow ſmall long leaves like unto Line or Flaxe, or ſomewhat reſembling thoſe of Lavander, but thinnely ſet all along upon the branches; the flowers are moſſie or threddy, and of a pale yellowiſh gerene coluor, like unto thoſe of the Olive tree, or of the Male Cornell tree; where afterwards come ſmall round berries, greene at the firſt, but red as Corrall, or like the berries of Aſparagus when they are ripe, of an aſtringent glutinous taſte, with ſome ſharpeneſſe joyned therewhith, wherein is contained an hard ſtone, having a white ſweete kernell within it: the roote is hard and wooddy.

Caſſia poetica Monſpelienſium.
The red berried ſhrubbe Caſſia.

The Place.

It groweth by the high wayes, in many places of *Spaine*, both in the countries of *Granado* and *Valentia*, and *Sivill*, as alſo in divers places of *Provence* in *France*, about the hedges and bordres of the Olive yeards: by the bankes alſo of the river *Lanus*, and about the village *Peraul*, not farre from *Mompelier*, as alſo in a ſmall Wood or Coppiſe neare unto the Priory of *Egremont*, neere there adjoyning.

The Time.

It flowreth about *Iune* and *Iuly*, and the berries ripen not untill *September*.

The Names.

Cluſius ſaith that it was accounted for *Oſyris* of *Pliny*, while he lived at *Mompelier*, whereunto hee ſaith, it doth agree in many things, but afterward they called it Caſſia, but by what reaſon or 'cauſe it is not knowne, for it neither agreeth with that *Caſia* of *Dioſcorides* and *Galen*, which is like Cinamon, and is of a ſpicie taſte, called in Apothecaries ſhoppes *Caſſia lignea*, whereas this is nothing ſo: nor can it be the *Cneoron* of *Theophraſtus*, which as *Pliny* ſaith *Hyginus* called *Caſſia*, neither is it the ſweete ſmelling *Caſſia* of *Virgil*, whereof he ſpeaketh both in his *Bucolicks* and *Geargicks*; yet as I ſaid they of *Mompelier* did call it *Caſia*; and *Lobel Caſia Poetica Monſpelienſium*: *Cluſius* calleth it *Caſia quorundum*, and ſaith that *Placa* a Phiſition and profeſſor in *Valentia*, called it *Polygonum Plinij*; and ſo doth *Dalechampius* upon *Pliny* call it *Polygonum 4. Plinij*: *Lugdunenſis* calleth it *Caſia lignea maritima*: *Cæſalpinus Caſia lignea*, and *Geniſta rubra*, becauſe the ſtalkes and the leaves will ſometimes grow red towards the end of Summer: and *Bauhinus Oſyris fruteſcens baccifera*, numbring it among the *Linarias*, becauſe of the leaves; and that he would make it to be the *Oſyris* of *Pliny*, *lib. 27. cap. 12.* as they of *Mompelier* at the firſt did, which hee there ſaith, hath ſmall gentle or pliant branches, with blacke leaves thereon like Lin, and a ſeede blacke at the firſt, and becomming red afterward, and citing *Galen* in his eigh Booke of Simples, that ſaith, of *Oſyris* is made κορήματα for women, which ſome interpret *Smegmata*, but *Pliny* ſaith *Scopas*, *alij* κόσμησεως χάριν καλλωπίσματα: but in my mind *Pliny* hath not truely, related the words of *Dioſcorides* and *Galen*, who both ſay that the leaves of *Oſyris* are firſt black and then red, which he inverteth to the berries, which make a great alteration of ſenſe; and *Bauhinus*, to make this plant his *Oſyris*, taketh him thus corrupted, which yet is not found, that the berries ſhould be blacke before they be red.

The

The Vertues.

We have little recorded of any especiall cure this hath performed, or that it is applied to those that are sicke of any disease; for although all doe agree that it is of a drying, glutinous and astringent taste, and might no doubt be effectuall for laskes and fluxes of bloud and humours in men and women, and to performe whatsoever the astringent and drying propertie might, as in *Polygonum* promise to performe, yet there is nothing determined, and therefore I dare not play the Phisition to invent new receipts, for the cure of old diseases: it is sufficient to declare the temperature and what others have used or approinted, when I have no new thing to shew.

CHAP. XIX.

1. *Asperula repens Gesneri, sive Saxifraga altera Cæsalpini.* Breakestone Woodroofe.

THis small plant which is accounted a kinde of Saxifrage in some places of *Italy*, resembling in the outward face and forme *Rubia minor*, *Asperula*, *Gallium*, and such other like herbes, doth cause me to joyne it with them, as being a *congener* of one tribe and family; how therefore to know this plant is in this manner. It spreadeth upon the ground for the most part (and yet in some places standeth more upright) divers small tender stalkes, separated into other smaller branches, of about a foote high, full of joynts, at which come forth three, foure, or more sometimes, small and narrow smooth leaves: the flowers stand at the toppes of the branches, many set together in a tuft, which are long small and reddish, and after they are past groweth, rough, crooked seede, which is small and blackish; the roote is small and threddie, and browniſh on the outside.

2. *Rubia Cynanchica saxatilis.* Stone Woodroofe.

This other small Woodroofe, is very like unto the former, but that it is smaller and lower, not past an hand breadth high, and the leaves much smaller, the flowers also of a pale red colour, many tufting together, and every one standing upon a short foote stalke: the seedes and rootes are like the other.

3. *Iuncaria Salmaticensis.*
Small stone Woodroofe of *Spaine.*

This small plant is likewise very like unto the first, growing more upright with square, rough rushlike branches, spreading forth into many small sprayes, almost like unto an Horsetaile grasse full of joints, with two leaves and sometimes with more at a joint, somewhat long & narrow like unto Line or Flaxe, but rough: at the toppes of the branches come forth many small white flowers set in spikes, and foure or five standing upon a short foote stalke together, which stand in rough huskes, wherein commeth the seede, which is blacke and small; the roote is white and threddy like the other.

The Place.

The first groweth in shady Woods in many places of *Italy*, and *Germany*; the second about *Valentia* in *Daulphine* in *France*: the last about *Salamanca* in *Spaine* as *Clusius* saith; but I found it on the right hand of *Bradford* bridge at the lower end of *Grayes Inne-Lane* by *London*, neare the water course that passeth along thereby.

The Time.

They doe all flower and seede in the end of Sommer.

The Names.

The first is called by *Gesner in libello de collectione stirpium Asperula herba repens*, and is the second Saxifrage of *Cæsalpinus*; *Bauhinus* referreth it to the *Synanthyca* of *Ludgunensis*, and to the *Gallium montanum latifolium cruciatum* of *Columna*, and calleth it himselfe *Rubia Cynanchica*: the second he setteth forth in his *Prodromus*, under the title I have here expressed it; the last is called by *Clusius Iuncaria Salmaticensis*, and *Synanchicæ species* of *Lugdunensis*, by *Tabermontanus Iuncaria*, but by *Bauhinus Rubia linifolia aspera.*

The Vertues.

The *Italians* as I said in divers places of their countrie doe use the first kinde to helpe those that are troubled with the stone or gravell in their kidneyes, by provoking urine, which washing or passing by the uritories, carrieth with it small gravell, and fretting the stone into gravell, sendeth it forth with the urine: it conferreth likewise much helpe to those that are troubled with the Quinsie, which is an inflammation of the kernells of the throat, which by the extreme paine thereof is ready to stoppe the breath, and doth sometimes suddenly happen so indeede: it is a disease that Dogges and Wolves, are much subject unto, for it is derived from the Greeke word ἀγχόνη *laqueus*, in that we usually hang up such Dogges that are troubled therewith, or else that the disease

is

is as a gibbet to hang them; or from the Greeke word συνάχειν, *quod ſpiritum continendo reſpirationem inhibeat*: Of the other two ſorts, there is not any that hath mentioned any uſe they are put to in Phyſicke, or otherwiſe.

CHAP. XX.

Aſparagus. *Aſperagus* or Spërage.

I Have in my former Booke ſet forth thoſe ſorts of garden Sperage or Aſparagus, whoſe young buds are moſt uſually eaten with us, as a ſallet herbe of great eſteeme, whereof I ſhall not neede to make any repetition, but proceede and ſhew you the reſt of that kinde, whereof there are three or foure ſorts more.

2. *Aſparagus marinus craſſiore folio.* Sea or wild Aſparagus with thicker leaves.

This kinde of ſea or wild *Aſparagus* riſeth up with many, but ſhorter ſtalkes then the garden kindes doe, ſtronger alſo and thicker, branching forth in the ſame manner, and having ſuch like winged leaves, but ſhorter, thicker, harder, and of a blewiſh greene colour; the bloſſomes are like the other, and ſo are the berries or ſeede that follow, but greater than they, and not of ſo freſh a red colour: the roote ſpreadeth in the ground.

3. *Aſparagus ſylveſtris folijs acutis.* Wilde Aſparagus with ſharpe leaves.

This Aſparagus with ſharpe leaves, riſeth up from a head of rootes, whoſe ſtrings are thicker and ſhorter than any of the former kindes, with three or foure ſtalkes, which are ſhorter, ſtronger and whither then the other, diverſly ſpread and branched into many wings, whereon are ſet at ſeverall diſtances, many ſmall, ſhort, hard and ſharpe pointed leaves, five or ſixe ſtanding at a joint together: at theſe joints likewiſe with the leaves come forth the flowers, many ſet upon a long ſtalke, which are yellow, conſiſting of ſixe leaves apeece, ſmelling as ſweete as a *March* Violet; after which come ſmall berries, greene at the firſt, and of a blackiſh aſh colour when they are ripe, wherein is contained a hard blacke ſeede.

4. *Aſparagus petræus ſive Corruda aculeata.* Prickly rockë Aſparagus.

This kinde of thorny Aſparagus, that groweth in ſtony and rockie places, hath very thicke and ſhort rootes or ſtrings, many jointed together at the head, from whence riſe ſundry branched greene ſtalkes, having three or foure ſharpe greene thornes, more likely than leaves, they are ſo hard, ſmall, long, and ſharpe pointed, ſet together all along the ſtalkes and branches; whereat come forth, ſmall moſſie yellowiſh greene flowers, and after them ſtore of berries, greater than in the former, and of a blackiſh greene colour, when they are ripe, full of a greeniſh pulpe, wherein lieth uſually but one blacke hard ſeede, or at the moſt two, having a white kernell within it.

2. 3. *Aſparagus marinus craſſis, & folijs acutis.*
Aſparagus with thicke, and with prickly leaves.

4 *Aſparagus petreus ſive Corruda aculeata.*
Prickly rocke Aſparagus.

5. *Aſparagus*

5. *Asparagus spinosus, sive Corruda spinis horrida.* Asparagus with cruell sharpe thornes.

This thorny Asparagus shoot: th out from such a short, thicke, stringy roote as the last, but yellowish on the outside, two or three white crooked or bended stalkes, branched forth on every side, and at every joynt there, where the branches are bending and divided, and whereof the leaves are set also, standeth a most cruell sharpe thorne, growing downeward, and together with the thorne upon the younger branches, stand five or sixe small long, narrow and soft leaves, clustering together, which are of a sweetish clammie or gummie taste: at the joints likewise with the leaves, come forth the flowers, of a yellowish greene colour, each of them standing upon a long and slender foote stalke, hanging downeward: after which come in their places large roundish berries, red when they are ripe, seeming to be three square, full of a tough or clammie juyce, containing with it one blacke graine or seede, and seldome two.

5. *Asparagus spinosus sive Corruda spinis horrida.*
Asparagus with cruell sharpe thornes.

The Place.

This first kinde by transplanting is thought to become the garden kinde, and groweth in many low medowes that are nere the sea, as also in many other places further of, the coasts as I doe heare; for it is thought that it is this kinde that groweth in the Marshes of *Tidnam*, neare *Chipstoll*, and in *Apleton* medow in *Glostershire*, which is about two miles from *Bristow*, from whence the poore people doe gather the buddes or young shootes, and sell them in the markets of *Bristow*, much cheaper then our garden kinde is sold at *London*: the second groweth in stony and rockie places, neare unto *Salamanca* in *Spaine*, and not onely under the hedges, but in the very fields also in *Castile* and *Ganado*, and about *Narbone* and *Mompelier* in *France*, and in *Candy* also: the third groweth both by hedges side, and in many stony and ragged places, both in *Spaine* and *Portugall*, and in *Candy* also as *Bellonius* saith: the last groweth also in rough uneven places, very plentifull about *Lisshborne*, in the common wayes, and by the river *Tagus*, and in many other places, both in *Spaine* and *Portugall*, and in *Candy* likewise; but it will hardly endure our cold climate.

The Time.

They doe for the most part all flower, and beare their berries late in the yeare, and scarse at all with us, although they be housed in Winter.

The Names.

It is called in Greeke ἀσπάραγος and ἀσφαράγος, *Asparagus* and *Aspharagus*. *Varro* saith, *quia ex asperis virgultis ligetur*; *Pompeius Grammaticus*, *quod in aspera virgulta nascitur*; but as *Galen* saith the first budding of any herbe that was used to be eaten, after it was sprung from the seede, was called *Asparagus*, as in Cabbage, Lettice, and the like buddes, or shootes of herbes; but in speciall, and as most deserving this hath kept the name peculiar to it selfe. It is called also in Latine *Corruda, quod ubi adolevit facile corruat decidatq;*. *Pliny* saith the *Athenians* called it ὁρμινον *Horminion*, ἀπὸ τῦ ὁρμῶ, *quod est ruo*, say some, but others thinke it to be derived ἀπο τῦ ὀρμᾶν, *nam & decoctum & semen Veneris causa bibitur*: the *Arabians* call it *Halion* or *Helion*, the *Italians Asparago*; the *Spaniards Asparagos*; the *French Asparge*; the *Germans Spargen*; the *Dutch Corallcraut*, in *English* Sperage or Asparagus: the first sort is to be understood of that kind which is set forth in my former Book: the second is called by *Matthiolus*, *Anguilara*, and *Tabermontanus*, *Asparagus palustris*; by *Lobel* and *Pena* in their *Adversaria*, *Asparagus maritimus Dioscoridis*, by *Clusius* and *Camerarius*, *Asparagus marinus*, and by *Bauhinus Asparagus maritimus crassiore folio*: the third is generally thought to be the *Asparagus petræus* of *Dioscorides* and *Galen*, which he saith is also called *Myacanthus*, in his sixth Booke of Simples or simple medicines, and of *Pliny Corruda*, or *Sylvestris Asparagus*. *Theophrastus* in his sixth Booke and first Chapter, saith that *Asparagus* (without giving it any another Epithite, which it must be understood of this kinde) and *Scorpio* are nothing but thornes, for they have no leaves. *Matthiolus* and *Tabermontanus* call it *Asparagus petræus*, and *Corruda*; *Gesner*, *Dodoneus*, *Camerarius*, and others, call it *Asparagus Sylvestris*; *Clusius Corruda prior*. *Cordus*, *Lobel*, *Lugdunensis* and others *Corruda*, and *Bauhinus* as I doe, *Asparagus foliis acutis*: the fourth is called by *Clusius Corruda altera*, by *Lobel Corruda Hispanica*; and so doe *Lugdunensis* and *Tabermontanus*, by *Dodoneus Asparagus Sylvestris*; and by *Bauhinus Asparagus aculeatus alter tribus, aut quatuor spinis ad eundem exortum*: the last is called by *Clusius*, *Corrudatertia*: *Bellonius* in his first Book of Observations, and 18. Chapter, saith, that they of *Creete*, called it *Polytricha*; by *Dodoneus Asparagus Sylvestris tertius*; *Lobel* and *Lugdunensis* call it as *Clusius* doth, *Corruda tertia*, and *Bauhinus aculeatus spinis horridus*.

The Vertues.

The young buds or shootes or branches of any of these sorts of Asparagus boyled, are more powerfull in Physicke to helpe diseased persons then the Garden kinde: the buddes or branches boyled in ones ordinary broth helpeth to open the belly, and to make it soluble, and either they or the rootes boyled in wine, provoke urine being stopped: and is good also against the hardnesse or difficulty to make water, or the Strangury when it commeth by drops, and to expell gravell and the stone out of the kidneyes, and helpeth also other paines in the reines

reines and backe; it is very good to be given to ſuch as are troubled with the jaundiſe, and taken in wine, helpeth thoſe that are bitten by the *Phalangium*, or great poyſonous ſpider, and other Serpents; being boyled in wine or vinegar, it is good for thoſe that have their arteries looſened, and are troubled with the hippe-gout, or Sciatica: the rootes boyled in wine and taken, are ſaid to helpe the frenſy, and the falling ſickneſſe, and to eaſe the paines of the mother in women; the decoction thereof likewiſe is good to cleare the ſight that is dimme and miſty, and being held in the mouth warme, eaſeth the tooth-ache; the ſame alſo healeth the paines of the breaſt, ſtomacke, and bowels, and taken every morning faſting for certaine daies together; ſtirreth up bodily luſt in man or woman, although ſome have written the contrary, that it hindereth conception and cauſeth barrenneſſe, *Chryſippus* ſaith that three ſcruples of the ſeed of Aſparagus, Smallage and Cummin, being given in three or foure ounces of wine, for five dayes continually, to them that make a bloody water, it will helpe them; and he ſaith alſo that it is not good for any that hath a dropſie to take thereof, but rather is an enemy and will doe them harme, although it be powerfull to provoke urine. *Avicen* ſaith, that it cauſeth the body to have a ſweete ſavour, to take the buds as meate, but it doth render the urine ſtincking: it diſſolveth the wind in the ſtomacke, liver, and guts, and the paines of the chollicke, which riſe of pituitous and thicke flegmaticke humours: the Garden Aſparagus nouriſheth more then the wilde kindes, yet hath it alſo his effects, both in the urine, reines, and bladder, in opening the body gently, and many other the forenamed diſeaſes, but this inconvenience happeneth by all medicines that ſtrongly provoke urine, if they be too frequently uſed, they doe exulcerate the bladder: many doe uſe the ſeede of Aſparagus, for all the purpoſes before written, and hold them as effectuall as the rootes; the decoction of the rootes or ſeede made in wine, and the backe and belly bathed therewith, or to ſit therein as in a bath, but kneeling or lying low that they may ſit the deeper therein, hath beene found to be effectuall againſt the paines of the reines kidneys and bladder, the paines of the mother and of the chollicke, and generally all thoſe paines and torments that happen to the lower members of the body, it is no leſſe effectuall alſo againſt ſtiffe and benummed ſinewes, or thoſe that are ſhrunke by crampes, or convulſions, and the paines of the hippes called Sciatica; it is ſaid that whoſoever ſhall moiſten their hands, face, necke, or any other part of the skinne, with the decoction or juice of Aſparagus, there ſhall no Bee, Waſpe, Hornet, or other ſuch like flye ſting them. *Dioſcorides* ſaith, that divers did affirme in his time, that if the decoction of it be given to a dogge to drinke it will kill him, divers fabulous things have beene obtruded for truth, in the writings of the ancient, and the moderne writers alſo, if they either follow the traditions of their elders, without conſideration of the probability, or examination of the verity, or elſe are led by vulgar reports, whereof this is one in the text of *Dioſcorides*, which himſelfe holdeth to be falſe, and untrue, becauſe it is ſo unlike in reaſon and nature, that if Rammes horne be beaten or bruiſed, and buried in the ground, from thence ſhall riſe Aſparagus; ſome have affirmed alſo, that if you ſow the ſeede of Aſparagus in canes ſtucke in the ground, they will grow the ſweeter and more pleaſant in taſte, becauſe they ſay the Aſparagus, and the Cane or Reede, have a great ſimpathy one unto another, which how true or likely it is, I leave to every one to beleeve as they liſt; but the practiſe of many Gardiners that nurſe Aſparagus for their profit, is to have canes cut of ſeverall lengths, ſome ſhorter ſome longer, which they ſticke over the heads or ſhootes of the Aſparagus, whereby they ſay the buds are made the tenderer, and more delicate to be eaten; which peradventure may be likely in ſome part, as all other ſallet herbes that are whited by covering them, or keeping them from the ayre, and are thereby cauſed to be the tenderer, onely by concocting the ſuperfluous moiſture in them, but I cannot beleeve that it commeth from any vertue or ſimpathy of the cane thereunto; if this be not true and probable, let others bring more probability, and I will yeeld unto it.

CHAP. XXI.

Linaria. Tode Flaxe, or Flaxeweede.

OF the *Linaria* or Todeflaxe, there are many ſorts, ſome whereof (that is the moſt beautifull) I have ſet forth in my former booke, which are theſe. *Linaria purpurea ſive cærulea*, Purple or blew Todeflaxe. *Linaria purpurea odorata.* Sweete purple Todeflaxe. *Linaria Valentina.* Todeflaxe of *Valentia.* And *Linaria magna ſive Scoparia Belvidere dicta Italorum.* Broome Todeflaxe, which I ſhall not neede againe to deſcribe here, but of the reſt not there expreſſed. And becauſe of the great variety I would uſe this method in ſetting them forth, firſt to place thoſe that grow upright, and have broader leaves, then next, thoſe that have narrower leaves, and yet grow upright, and laſtly of the ſmalleſt kinds, that creepe upon the ground.

Linariæ erectæ Latifoliæ. Vpright broad leafed Flaxeweedes.

1. *Linaria latifolia Dalmatica.* The great *Dalmatian* Flaxeweede.

THe great Flaxeweede of *Dalmatia*, hath divers faire large greene leaves, ſpreading upon the ground, being about two inches long, and one broad, ending very ſharpe pointed, without any footeſtalke at them, but riſing up with the ſtalke, which is firme hard and round, about two or three foote high, hath the like leaves ſet thereon, without any order up to the toppe, but leſſer as they grow higher: the ſtalke is branched at the toppe, having at every one of the branches, ſuch like ſpikes of deepe or gold yellow flowers, as are in the common wild kinde, with ſpurres behind them; but each of them are three or foure times larger then the common; the ſeed is like the wilde kind, and encloſed in the like heads, but larger alſo, the roote is white, and ſpreadeth ſome branches under ground, and periſheth not as the wild kinde doth, but abideth in the winter, with both roote and ſtalke, ſhooting freſh leaves every Spring.

2. *Linaria Latifolia Cretica major.* The great broadleafed Flaxeweede of *Candy*.

This Flaxeweede of *Candy* ſendeth from the roote a round thicke ſtalke, two or three foote high, ſpread into many

many branches, whereon are ſet ſometimes two and ſometimes three leaves together, on a ſmall footeſtalke, on each ſide of them, ſometimes one againſt another, and other times keeping no order, each whereof is larger and longer then the former, and of a grayiſh greene colour, with three veines or ribbes in every one of them: at the tops of the branches grow flowers, made for the forme like the other kinds, but of a differing colour, for the gaping mouth is of a pale blew colour, and more yellow underneath, with a pale or blewiſh, and ſometimes more purpliſh ſpurre behind; the heads and ſeede are like the wild kinde; the roote is hard and white, bigger at the head and ſmall below with ſome fibres thereat.

3. *Linaria Americana parvo flore.* The yellow Flaxeweede of *America*.

This Indian kinde ſhooteth forth divers ſlender ſmall reddiſh ſtalkes, ſpread into many branches, whereon grow on both ſides of them, yet without order, many darke greene leaves, much narrower but not much ſhorter then the former, ending alſo in a ſharpe point; the flowers grow at the toppes of the ſtalkes, in the ſame manner that the common wilde kinde doth, and of a gold yellow colour, but much leſſer then they.

4. *Oſyris ſive Linaria alba.*
White flowred Flaxeweede.

4. *Linaria ſive Oſyris alba.*
White flowred Flaxeweede.

The white Flaxeweede riſeth up with many tough pliant ſtalkes with long narrow leaves ſet thereon, ſomewhat like thoſe of the common ſort, at the toppes whereof ſtand ſundry pale whitiſh flowers reſembling the ordinary kinde, but with a wider and more open mouth: the ſeede is not unlike the other, the rootes are white, long, thicke and great, abiding divers yeares and not periſhing.

5. *Linaria triphylla cærulea Apula.*
The blew Flaxeweede of *Naples*.

This blew Flaxeweede of *Naples*, hath at the joynts of the white ſtalkes which are ſometimes but one, and ſometimes more, three leaves ſet together, divided almoſt like Rue leaves but greater, deeper cut in, and pointed at the ends, of a grayiſh greene or aſh-colour; the toppe of the ſtalkes are furniſhed with ſuch like flowers, but ſmaller and of a blew colour wholly, except the mouth which is yellow, after which come ſmall round heads, conteining large flat and blackiſh ſeed, the roote is ſmall and white.

The Place.

The firſt according to the title you may know came from *Dalmatia*, but from what place there, is not ſignified. The ſecond from *Candy*. The third from *America*. The fourth, in gardens: the laſt from *Naples*.

The Time.

They doe all flower in the Sommer moneths, yet ſome ſooner or later then others, for thoſe of *America* flowreth very late, and ſcarſe give ripe ſeede any yeare.

The Names.

It hath no Greeke name that I can finde mentioned by any author, but in Latine it is called P*ſeudo Linum*, and *Linaria*, for the reſemblance that the leaves of the wilde common kinde have with Line or Flaxe, and *Vrinalis* and *Vrinaria* from the effects. Some have called it *Eſula adulterina*, for the reſemblance it hath with the little *Eſula*; whereupon came this verſe, *Eſula lacteſcit, ſive lacte Linaria creſcit*. Divers have taken it to be the *Antirrhinum* of P*liny*, it may be *Oſyris* both of P*liny*, *Dioſcorides*, and *Galen*, whereunto in moſt mens judgements it doth in many things agree; and ſome as *Matthiolus* ſaith, would make *Belvidere* to be *Oſyris*, which is called by ſome *Herba ſtudioſorum* the Schollers herbe, but becauſe they make their *Oſyris* to have foure or five leaves onely on the ſtalkes, and that they ſerve for broomes to ſweepe withall; for the Greeke word κορήματα (but καχορήματα, as ſome copies have it is falſe,) doth as well ſignifie *ſcopas* broomes, as *Coſmetica*, ſuch things as beautifie the skin, I cannot ſee well how it ſhould agree thereunto: the *Italians* and *Spaniards* call it *Linaria*, the *French Lin Sauvage*; the *Germanes Lin kraut*, *Horn kraut*, and *Flachs kraut*. The *Dutch Wilt Vlas*. In *Engliſh* we call it Wildeflaxe, Todeflaxe, and Flaxeweede. *Bauhinus* in his P*rodromus* maketh mention of the third, but calleth it himſelfe in his P*rodromus* and *Pinax Linaria latifolia triphylla*; but referreth the ſecond to the *Cretica Latifolia* of *Cluſius*. The fourth is called *Oſyris alba* by *Lobel* in his *Dutch* Herball. The laſt *Fabius Columna* mentioneth.

Linariæ erectæ anguſtifoliæ. Vpright and narrow leafed Flaxeweedes.

1. *Linaria vulgaris noſtras.* Our common wilde Flaxeweede.

OVr common Flaxeweede that groweth wild in all countries of this Land as well as beyond Sea, is ſo well knowne unto all, that are never ſo little converſant in herbes, that it were almoſt needeleſſe to deſcribe it to have divers ſtalkes, full fraught with long and narrow, blew or aſhcoloured leaves; and from the middle of them almoſt upwards, ſtored with a number of pale yellow flowers, of a ſtrong unpleaſant ſent, with deeper yellow mouthes, and blakiſh flat ſeedes in round heads, the roote is ſomewhat wooddy and white, eſpecially the maine downeright one, with many fibres, abiding many yeares, ſhooting forth rootes every way round about, and new branches every yeare.

2. *Linaria Pannonica major.* The great Flaxeweede of *Hungary.*

This is in many things like the former, but that the leaves are larger and the flowers greater and fewer then it, and of a pale yellow colour, but a deeper yellow in the mouth, with some hairineſſe therein.

3. *Linaria Cretica anguſtifolia.* The narrow leafed Flaxeweede of *Candy.*

This Flaxeweede of *Candy*, hath at the three lower joynts of the ſtalkes, which are many, and of a foote and a halfe high, foure long leaves a peece, but narrower by the halfe then the former, but at the reſt of the joynts, they ſtand without order, growing ſtill ſmaller as they riſe higher upon the ſtalkes, which are much divided towards the toppes, whereon ſtand ſuch like flowers as the former, but ſmaller and of a whitiſh aſh colour, the ſpurre behind them being of the ſame colour, the ſeede and ſeed veſſels are not unlike the former, but quickly fall away, even while the plant remaineth greene.

4. *Linaria Hiſpanica tertia Cluſij.* *Cluſius* his third Spaniſh Flaxeweede.

The third Spaniſh Flaxeweede of *Gluſius* ſheweth from the roote many ſmall ſtalkes, about a foote high or more, whereon grow very plentifully many narrow leaves, of a grayiſh or aſh colour, and at the toppes of them ſtore of ſmall flowers, that are of a whitiſh colour on the outſide, and more purpliſh inwardly, about the gaping mouth, being of a more yellow colour, but yet pale alſo, the ſpurre behinde being of a purpliſh colour; the ſeede that followeth, when it hath any, for it ſeldome beareth, is like the other, but doth recompence that defect, in that the roote periſheth not, but abideth and encreaſeth every yeare.

5. *Linaria Caryophyllata albicans.* The ſweete white Flaxeweede.

This ſweete Flaxeweede hath upright ſtalkes ſomewhat wooddy, wherein are ſet without order, divers narrow and ſomewhat long leaves, yet ſhorter then the common kinde, and of a pale greene colour; the flowers ſtand not ſo thicke at the toppe of the ſtalkes and branches, nor fully ſo large, but are of a very pale yellow colour, almoſt white, and in other of a pale blew and white mixt, with a yellow mouth, the ſeede is like the common, and the roote periſheth not.

6. *Pſeudo-linaria montana alba.* The baſe white Mountaine Flaxeweede.

This baſe mountaine Flaxeweede hath ſlender ſtraked ſtalkes, with divers long and narrow leaves on them, both ſtalkes and leaves of a yellowiſh greene colour, diverſly ſpread into branches, from the bottome to the top, bearing on every one of them, a ſmall white flower, ſtanding on a ſmall footeſtalke, after which come darke grayiſh flat ſeede, in greeniſh yellow round heads, but very ſmall.

7. *Linaria tenuifolia Lugdunenſis.* Todeflaxe with very narrow leaves.

This Todeflaxe hath as narrow ſmall leaves as any other ſort, ſet very thicke on the low round ſtalkes, ſeldome above a foote high, of a bitteriſh auſtere taſte, that one cannot well tell which hath the predominancy, the branched ſtalkes have nothing ſo many flowers on the toppes of them, nor ſo cloſely ſet together, ſomewhat reddiſh while they are in the bud, but of a whitiſh red when they are open; after which commeth the ſeede which is ſmall and flat, contained in ſmall and long heads, the roote is blacke and full of threds.

1. *Linaria vulgaris noſtras.*
Our common wilde Todeflaxe:

2. *Linaria Pannonica major.*
The greater Flaxeweede of *Hungary.*

6. *Pseudo-linaria montana alba.*
The base white mountaine Flaxeweede.

Linaria odorata.
Sweete Flaxeweede.

Linaria Valentina Clusij.
Spanish Flaxeweede.

9. *Linaria minor cærulea.*
Small upright blew Flaxeweede.

8. *Linaria minima erecta.* The leaſt upright Todeflaxe.

This Todeflaxe, being the leaſt of all the former, and but that it doth not creepe, might elſe have beene ſet in the next ranke; hath one ſmall ſtalke not above halfe a foote high, whereon grow very many ſmall narrow blewiſh greene leaves, like the common wilde kinde, and at the toppe many ſmall pale yellow colour, with a ſpot in the jaw or mouth; the ſeede is exceeding ſmall blackiſh and flat, the roote is ſmall and periſheth every yeare, riſing againe from its owne ſowing.

9. *Linaria minor cærulea recta.* Small upright blew Flaxeweede.

This ſmall plant hath ſundry ſmall ſtalkes, of very ſmall ſhort leaves ſet one againſt another, of the ſame blewiſh greene colour with the laſt, from among which riſe up two or three ſtalkes, ſcarſe halfe a foote high, bearing longer and narrower leaves thereon, with larger flowers then the laſt, and of a blewiſh colour; after which come ſmall ſeede like the laſt: the roote is threddy and periſheth every yeare.

The Place.

The firſt as I ſaid groweth every where throughout the whole land, both in the way ſides in medowes, as alſo by hedge ſides, and upon the ſides of banks and borders of fields: the ſecond in many places in *Germany* and *Hungary*; the third in *Candy*, the fourth in *Spaine*, the fifth is not certainely knowne where: the ſixt on the hils in *Saxony*, as *Iohannes Thalius* ſaith: the ſeaventh in barren dry and open places, the eight and the laſt we know not whence their originall are, but came with divers other ſeedes that were ſent us from beyond the Seas.

The Time.

Theſe flower in Sommer, and their ſeede is ripe uſually before *Auguſt* be paſt.

The Names.

The firſt is called *Linaria* and *Pſeudolinum* by *Brunfelſius*, *Lonicerus* and *Dodonæus*; of *Matthiolus*, *Fuſchius*, *Cordus*, and *Lobel*, *Oſyris*. The ſecond *Camerarius* mentioneth in his *hortus Medicus*: The third, *Cluſius* ſaith the ſeede came from *Candy*, and grew in *Iohn Hogheland* his Garden; and is very probable to be both the *Linaria tetraphylla* of *Columna*, and the *arvenſis cærulea* of *Bauhinus*. The fourth is *Cluſius* his *Hiſpanica tertia*. The fifth *Camerarius* in *horto medico* ſaith it was ſo called in his time. The ſixth is mentioned by *Iohannes Thalius*, in the deſcription of *Harcynia ſylva*, by the name of *Linaria montana ſive ſylveſtris*, and as *Bauhinus* thinketh, is the *Anonymo Linifolio* of *Cluſius*, and the *Linaria adulterina* of *Tabermontanus*. The ſeaventh *Lugdunenſis* calleth *Linaria tenuifolia*, and *Bauhinus Linaria capillaceo folio*. The eighth is called *minima* not having any other epithite. And the laſt *minor cærulea recta*.

Linariæ minimæ repentes. The leaſt and creeping Flaxeweedes.

1. *Linaria pumila Hiſpanica.* The dwarfe Spaniſh Flaxeweedes.

THis dwarfe Todeflaxe of *Spaine*, ſhooteth up many tender weake branches, not able to ſtand upright, and riſing to be about an handbreadth or halfe a foote high, whereon grow many long and narrow leaves very like unto the common wilde kind, as well for forme as colour, and ſo are alſo the flowers at the toppes of the ſtalkes, but leſſer by much; the heads and ſeed are alſo like it, and the roote ſmall and white, and creeping under ground.

2. *Linaria parvà Hiſpanica altera.* Another ſmall Spaniſh Flaxeweede.

This other ſmall Spaniſh Flaxeweede hath divers weake ſlender branches, with many ſmall narrow leaves ſet about them, but fatter or thicker in handling, and ſomewhat leſſer alſo then the laſt, and of an aſh colour; the toppes of the ſtalkes are furniſhed with a great many ſmall flowers, of a pale blewiſh or aſh colour, with a yellow ſpot in the mouth or gaping place, the ſeed and ſeede veſſels are ſmall according to the proportion of the plant, the roote is ſmall and white, and periſheth every yeare.

3 *Linaria Hiſpanica atro purpurea repens.* The creeping darke purple Spaniſh Flaxeweede.

This Spaniſh kinde alſo hath many weake trayling branches, whereon grow many ſmall ſoft aſh coloured leaves; at the toppes of the ſtalkes grow many flowers, ſomewhat larger then the laſt, of a ſad purple colour, almoſt

1. *Linara pumila Hiſpanica.* The dwarfe *Spaniſh* Flaxeweede.

blackiſh

blackish, with pale yellow spots in the mouthes of them, of a pretty sweete sent, the seedes and rootes are alike perishing every yeare.

4. *Linaria cærulea repens.* The small blew creeping Flaxeweede.

This small Flaxeweede sendeth from the roote, a number of small weake stalkes, leaning downe to the ground, scarse being able to stand upright, set without order, with many small and very narrow ashcoloured leaves up to the toppes, where they grow into divers other smaller branches, having a long head or spike of flowers, very small, and of a fine blewish purple colour, with a yellow spot in the mouth of them: the seede is not unlike the former; but the roote shooteth forth many fibres, and abideth, not perishing in the Winter.

5. *Linaria quadrifolia Alpina.* The Mountaine blew Flaxeweede.

This Mountaine Flaxeweede shooteth forth his small weake stalkes, lying almost upon the ground, diversly divided into many smaller branches, even from the bottome: upon which are set small short whitish greene leaves, very orderly at the severall joints, one above another, that is, at some but two leaves, at others three

4. *Linaria cærulea repens.* The small blew creeping Flaxeweede.

5. *Linaria quadrifolia Alpina.*
The blew mountaine Flaxeweede.

Linaria Africana pinnato Helxines folio.
African Flaxeweede with black: Bindeweede-like leaves.

or foure, not keeping alwayes proportion in the number, especially below, but rather upward; the flowers that ſtand at the toppes of the branches, are in forme like the other, and ſomewhat great, but ſtand not ſo thicke cluſtering together, being of a daintie purple blew colour, with a yellow ſpot in the mouth: the heads for ſeede that follow, are ſomewhat great, having blackiſh flat ſeede within them: the roote is ſmall and white, ſpreading divers wayes under ground, and periſheth not in the Winter.

6. Linaria lutea Moravica Cluſij. The ſmall yellow *Moravia* Flaxeweede.

This ſmall kinde of Todeflaxe, is ſomewhat like unto the laſt kinde in the precedent ranke, but that it hath more ſtore of ſtalkes, that doe not ſtand upright, having many ſmall aſh coloured leaves, ſet upon them, which are rounder and more ſappy: the ſtalkes beare at the toppes of them many yellow flowers, with yellower ſpots in them, but the leaſt of all theſe in this third ranke: the ſeede is ſmall and blacke, and the roote periſheth every yeare.

The Place.

The firſt groweth about *Salamanca* in *Spaine*: the ſecond and third in ſome other parts of *Spaine*; it is not certainely knowne where: the fourth on the hills in *Moravia*, as the laſt doth alſo; the fift groweth as well in *Stiria* as *Cluſius* ſaith, as among the *Switzers* and the hills in *Rhætia*.

The Time.

They doe all flower in Sommer, and give their ſeede quickly after.

The Names.

The firſt is the fift *Spaniſh* kinde of *Cluſius*, which *Bauhinus* calleth *Oſyris flava ſylveſtris*, and *Tabermontanus Oſyris minor*: the ſecond is the fourth *Spaniſh* kinde of *Cluſius*, as the third is his ſecond *Spaniſh* kinde: the fourth is *Cluſius* his ſecond *Linaria* of *Moravia*, as the laſt is his firſt *Moravian* kinde: the fift is called by *Cluſius Linaria Stiriaca*, by *Geſner in hortis Germaniæ*, and in his Epiſtles *Linaria Alpina & Helvetica*: by *Tabermontanus Linaria Alpina pumila*, and by *Bauhinus*, *Linaria quadrifolia ſupina*: the laſt is called by *Cluſius Linaria Moravica prima* in his Hiſtory.

The Vertues.

All theſe ſorts are in ſome degree, more or leſſe effectuall, but the moſt common kinde is the moſt uſed, to provoke urine, both when it is ſtopped, as alſo in thoſe that are troubled with the dropſie, to ſpend the abundance of thoſe watery humours by urine, and by the drawing downe of much vrine, doth in ſome ſort helpe to waſh the reines and uritory parts from gravell or ſtones gathered therein: the decoction of the herbe, both leaves and flowers in wine, taken and drunke doth ſomewhat move the belly downewards, openeth the obſtructions of the liver, and helpeth the yellow jaundiſe, expelleth poiſon, provoketh womens courſes, driveth forth the afterbirth and dead child: the diſtilled water of the herbe and flowers is effectuall for all the ſame purpoſes, and in eſpeciall being drunke with a dramme of the powder of the ſeedes, or barke of the roote of Wallwort, and a little Cinamon for certaine dayes together, is held to be a ſingular remedy for the dropſie, to ſpend the water and humors: the juice of the herbe or the diſtilled water dropped into the eyes is a certaine remedy for all heate, inflammation and redneſſe in the eyes: the juice or water put into foule ulcers, whether they be cancrous or fiſtulous with tents rowled therein, or the parts waſhed or injected therewith, clenſeth them throughly from the bottome, and healeth them up ſafely: the ſame juice or water alſo clenſeth the skinne wonderfully of all ſorts of deformity thereof, as lepry, morphew, ſcurffe, wheales, pimples, or any other ſpots and markes in the skinne, applied of it ſelfe, or uſed with ſome powder of *Lupines*.

CHAP. XXII.

Halicacabum ſive Alkakengi. Winter Cherries.

IN the reare of this Claſſis commeth the Winter Cherrie to be declared, whereof there are ſome other ſorts knowne to us more than in former times, as I ſhall preſently ſhew you.

1. Halicacabum ſive Alkakengi vulgare. The ordinary Winter Cherry.

The ordinary Winter Cherry is deſcribed unto you in my former Booke, therefore I doe here but onely make mention of it that you may take knowledge, the next is differing from it.

2. Halicacabum ſive Alkakengi Virginenſe. Virginian Winter Cherries.

This *Virginian* ſpreadeth the branches with leaves on the ground, ſcarſe raiſing it ſelfe up ſo much as the former, but the branches are greater, and ſo are the leaves alſo and more unevenly dented about the edges, of a ſad or ſullen greene colour, at the joints, come forth the flowers ſingly, that is one at a place and more toward the bottome than upwards to the height of the branches, which are rather ſmaller than the former, compoſed of five ſmall whitiſh leaves with a circle of red, or every leafe ſpotted circlewiſe towards the bottomes of them: the fruite that followeth is a ſmall berry, encloſed in a thinne skinne or bladder as the former, but greene and not red when it is full ripe, ſmaller likewiſe than it, the berrie filling the skinne or bladder more than it, and not leaving ſo much void roome in the bladder, as the former, yet hath it ſmall whitiſh ſeede within it as the other: the roote ſpreadeth under ground not very farre and periſheth in Winter. I have here onely given you three or foure leaves and a flower hereof with the figure of the former.

3. Halicacabum Indicum rectum. Vpright *Indian* Winter Cherries.

This *Indian* kinde riſeth up to be about foure foote high, with ſtrong upright ſtalkes, knotty and cornered, ſhooting out many branches, whereon grow faire greene leaves, like unto thoſe of the ordinary Winter Cherrie, but ſomewhat larger, and dented about the edges: at the joints with the leaves come forth the flowers, of a whitiſh colour as it is in the ordinary ſort, every one by it ſelfe, which are compoſed but of one leafe, having five corners, ſomewhat crumpled about the edges, and although they be not divided into five leaves, yet in the bottome of them there doth appeare five blackiſh purple ſpots in the bottome of every flower, with divers other purpliſh threds in the middle, tipt with blackiſh blew chives: after the flowers are paſt, there commeth in their places the fruit which are bladders or thinne skinnes, with berries in them like unto the ordinary Winter Cherrie,

rie, but that the berrie hereof is larger than the other, not onely filling the whole skinne or bladder, but oftentimes breaking it, and opening into foure parts, which when it is ripe, will be greene as well as the bladder; saving sometimes that part that hath the Sunne beames most upon it will be of a darke greenish purple colour; the whole plant is without taste, yet yeelding forth at the joints a certaine glutinous matter or juyce of a strong sent, like unto that of the *Poma amoris*, or Love apples: this perisheth every yeare in these colder climates, at the first approach of Winter; and whether it abideth in the naturall places, wee know not, nor to what physicall use it is applied, or whether it be used to be eaten.

1. 2. *Alkakengi sive Halicacabum vulgare & Virginense.* The ordinary and *Virginian* Winter Cherry.

The Place.

The first groweth by the hedge sides in moist and shadowie place, but is with us onely as I thinke cherished in gardens: the second came to us from *Virginia*, and grew with Mr. *Tradescant*; the last groweth in the West *Indies*, and was first brought into *Spaine*, and *Italy*, and from thence communicated first to *Camerarius* as I thinke, (for he first set it forth) and afterwards to others.

The Time.

They flower not untill the middle or later end of *Iuly*, and the fruit is ripe about the end of *August*, or beginning of *September*.

The Names.

Iosephus de Casa bona, sent the last sort from *Florence* to *Camerarius*, and called it *Halicacabum, sive Solanum Indicum*; some others have called it *Arborescens*, and *Solanum vesicarium Indicum*; I have added thereunto *rectũ* to distinguish it from the *Virginian* Winter Cherrie: but the ordinary kind, is one of the foure sorts of *Solana* or Nightshades, set forth and spoken of by *Dioscorides* and *Galen*, and one of the two of *Theophrastus* called *Solanum Halicacabum*; and by *Pliny Vesicarium*; either of the bladder wherein the berrie groweth, or of the vertues, against the diseases of the bladder and stone. Of the *Arabians Alkakengi*, which name the Apothecaries doe retaine to this day in their shops. *Brunfelsius* calleth it his *Saxifraga quarta* terming it *rubra*.

The Vertues.

Neither the *Virginian* nor *Indian* kinde are knowne to be used to helpe any griefe or disease. But our ordinary Winter Cherries are of great use, the leaves being cooling and may be used in all inflammations but not opening, as the berries or fruit are, which by opening the uritorie parts, and drawing downe the urine, provoke it to be avoided plentifully when it is stopped, or when it groweth hot, sharpe and painefull in the passage: and is good also to expell the stone and gravell out of the reines, kidnies, and bladder, helping to dissolve the stone, and avoiding it by greete or gravell, sent forth in the urine: it helpeth much also to cleanse inward impostumes or ulcers in the reines or bladder, or in those that avoid a bloudie or foule urine. It helpeth the jaundise also, by opening the passages of the gall and liver, and expelling it by urine. The distilled water of the fruit, or the leaves together with them, or the berries greene or drie, distilled with a little milke, is effectuall to all the purposes before specified, if it be drunke morning and evening with a little Sugar, and in speciall against the heate and sharpenesse of the urine. *Pliny* recordeth, that the roote hereof is so powerfull to stupifie the venome of the Scorpion, that if it be but put unto them, they will utterly lose all their strength; and being boiled in oyle and applied is powerfull against their sting. But because divers have appointed severall wayes, for the preparing and ordering of the berries hereof, to be helpefull for urine and the stone, I thinke it not amisse to remember some of them unto you. And first they appoint the berries to be put into new wine when it is new made and put up, that the wine working with the berries therein, may have their vertue therein, and serve them to drinke that are troubled in the manner aforesaid: but because our Land affordeth not wine to be made therein, I doubt not but our Beere or Ale will be as effectuall, having the same proportion of berries, that is three or foure good handfulls, either greene and fresh or dried, bruised and put thereinto, that is, into three or foure gallons when it is new tunned up, and after drunke in the same manner, and this drinke taken daily, hath beene found to doe much good to many, both to ease the paines and expell urine, and the stone in whom it is confirmed, and to cause it not to engender. Another way *Matthiolus* much commendeth, having used it many times himselfe, which is, to take some of the juyce of the berries in *Ptisane* drink made into a creame with Poppie seede, & the kernells of *Melon* or Pompion seede: also a decoction of Mallowes with some of the berries therein, or some of the juyce drunke in it: also sixe or nine drammes of the inward pulpe of *Cassia fistula*, drawne forth with the water or decoction of the berries, and given in a cupfull of the broth of fat flesh, wherein also some of the berries have beene boiled, is accounted an excellent remedie to cleanse the backe and reines, in those griefes of the stone and urine: the decoction of the berries in wine or water, is the most usuall way to be taken, and the powder of them taken in drinke or broth, I hold to be more effectuall.

Thus

Thus have I ſhewed you all the ſorts of Saxifrages or Breakeſtones, that are properly ſo called, for of divers herbes and plants that conduce to the ſame purpoſe, I have ſpoken in my former Booke, as you ſhall finde particularly quoted in the Table of remedies, under the name of *For the ſtone in the reines and kidnies*. There are divers other herbes alſo, availeable for the ſame purpoſe, but could not fitly be placed in this *Claſſis*, in that many of them are umbelliferous plants, ſome Thiſtles and ſome of other Tribes: all which could not without much confuſion be brought out of their owne ſtations, to fill up another. Take the reſt therefore of thoſe Breakeſtones, as you ſhall find them diſperſed throughout this whole Worke.

Now it behoveth me to intreate of other herbes, whoſe vertues are to heale wounds, and therefore called *Vulnerary* in the next *Claſſis*.

PLANTÆ

PLANTÆ VVLNERARIÆ ET FERRVMINANTES, *ID EST*, CONSOLIDANTES.

VVLNERARY OR VVOVND *HERBES.*

CLASSIS QVINTA, *THE FIFTH TRIBE.*

CHAP. I.

Centaurium majus. The greater Centory.

THE Dare not incline to the opinion of ſome of the *Arabian* Phiſitions and Writers that have ſaid the roote hereof is bitter, and thereby have added ſtrong purging qualities unto this kinde of Centory, which properly belong unto the leſſer kinde, thereby confounding them both together; for if I did, I muſt have placed it in the ſecond Claſſis among the purging plants. Neither dare I hold with the moderne errour of many, that hold the roote of this great Centory, to be the *Rhaponticum* of *Dioſcorides*, *Galen*, and others, they being ſo much differing one from another, as I ſhall ſhew you by and by. But as the qualities therein are moſt certaine to be Vulnerary, I have placed it here. Of this kinde there are three other ſorts knowne in theſe dayes, which were not formerly, which together therewith, ſhall be entreated of in this Chapter; and firſt of that which was firſt and commonly knowne.

1. *Centaurium majus vulgare.* The common great Centory.

The common great Centory, hath many large and long ſoft leaves, deepely cut in on the edges into many parts, notched or dented about the edges, of a pale greene colour on the upper ſide, and whitiſh underneath: the ſtalke is ſtrong and round, three or foure foote high, divided at the toppe into many branches, whereon ſtand large round ſcaly greene heads; ſhooting forth at their toppes, many ſmall threds or thrummes, of a pale blewiſh aſhcolour; wherein after they are fallen doe grow large whitiſh ſmooth ſhining ſeedes, ſomewhat like unto the ſeedes of Thiſtles, but larger, and lying among a great deale of downy matter: the roote groweth to be more than two foote long, and as great, as a reaſonable great Raddiſh or Parſneppe roote, blackiſh on the outſide, and ſomewhat reddiſh yellow within, abiding many yeares, ſending forth freſh leaves every Spring; thoſe dying for the moſt part, that were greene all the Sommer.

2. *Centaurium majus Pyrenæum.* The *Pyrenæan* great Centory.

This *Pyrenæan* kinde hath larger leaves than the former, and more jagged or cut in deepely on the edges, ſomewhat reſembling an Artichoke leafe in the diviſions, greene above and gray or as it were hoary underneath: the ſtalke riſeth to be about three foote high, cornered and hoary, having ſundry ſmaller leaves and leſſe jagged ſet thereon, and parted at the toppe into ſome branches, each bearing ſome ſmall leaves; under the heads which are much greater and more ſcaly alſo, with ſharpe prickes at their ends, like a little wilde Artichoke head: the tufts of threds which are the flowers, as in the other, are more purple: the ſeedes are white wrapped in downe like it, and the roote great and blacke on the outſide, but longer and of the bigneſſe of ones wreſt.

3. *Centaurium majus alterum ſive Luſitanicum.* The great Centory of *Portugall.*

This other great Centory hath many leaves, riſing from the head of the roote, lying almoſt upon the ground, which are as long and as large almoſt as the former, but without any jagge or diviſion at all in them, yet ſomewhat deepely dented about the edges, and of a deeper greene colour: the ſtalke is round and great, but riſeth not up ſo high, nor divided it ſelfe at the toppe into ſo many branches, but bearing onely two or three heads on a ſtalke, which are ſcaly in the ſame manner, & in it ſuch like thrums, of a pale whitiſh colour or threddy flowers; which being paſt, there groweth ſuch like ſeede alſo in thoſe heads, lying in a flockie or downie ſubſtance, but a little blacker, every one bearded in the ſame manner; the roote groweth to be as great, or greater than the former, blacke alſo on the outſide; and yellowiſh within, yeelding forth a yellowiſh red juice like the other, which is ſomewhat bitter, but a little more aromaticall than it.

4. *Centaurium*

1. *Centaurium majus vulgare.*
The common great *Centory.*

2. *Centaureum majus Pyrænium.*
The *Pyrenean* great Centory.

3. *Centaurium majus alterum sive Lusitanicum.*
The great Centory of *Portugal.*

4. *Centaurium majus luteum.*
The great yellow Centory.

4. *Centaurium majus Luteum.* The great yellow Centory.

This yellow Centory ſendeth forth many more, both larger and longer leaves from the roote then the former, ſome of the loweſt having fewer diviſions in them then others; but thoſe that grow upon the ſtalk, as wel as ſome of the other below, are very much divided into many parts, making every winged leafe to conſiſt of a dozen or ſixteene leaves, the ribbe in the middle betweene them being whitiſh, each for the moſt part ſet againſt another, with an odde one at the end, and every of them being narrow and long, without any dents on the edges, and of a whitiſh greene colour; the ſtalkes are many, ſtrong and round, ſomewhat ſtraked downe the length of them, each divided into ſome other branches, which beare ſomewhat greater ſcaly heads then any of the other and larger ſpread thrumbs or threds, of a fine lively pale yellow colour, which abide in their beauty a long time without decaying, but ſeldome giveth ſeede in this Country, becauſe as I thinke the ſcaly heads are ſo full of moiſture, that it hindereth ſeede to grow ripe therein; for if they be but a little preſſed betweene the fingers, there will iſſue forth on all ſides, ſmall cleare drops of water, as ſweete as Sugar almoſt, and that not onely at noone dayes as *Bauhinus* ſaith, but at any time of the day, and not for once onely and no more, but oftentimes; yea every day if ye will, it will yeeld ſtill ſome, as long as the flowers are freſh, and not quite withered, but when it doth perfect his ſeede, it is ſomewhat like the laſt great Centory, yet leſſer, blacker, and more ſhining: the roote groweth in time, to be greater then either of the other, having many heads, that ſhoote forth in the Spring, the old leaves dying downe to the ground every yeare, which is wrinkled and blacke on the outſide, and yellowiſh within, full of a ſlimy moiſture in them, running downe deepe into the ground with ſome greater branches, and but a few ſmall fibres.

The Place.

All theſe ſorts grow upon mountaines, the fifſt and third upon the *Alpes* and Mount *Baldus*; the ſecond on the *Pyrenean* hils; *Cluſius* ſaith, he found the third upon ſome ſtony hils, beyond *Liſborne* in *Portugall*, neare the river *Tagus*, and the laſt there likewiſe and on Mount *Baldus* as *Pona* ſaith.

The Time.

They doe all flower about the end of *Iune*, and in *Iuly*, yet the *Portingall* kinde doth leaſt endure our cold aire, ſeldome ſhewing forth his flower, nor yet abiding unleſſe well preſerved.

The Names.

It is called in Greeke κενταύριον τὸ μέγα *Centaurium magnum*, and as *Pliny* ſaith, tooke the name from *Chiron* the *Centaure*, who was healed herewith of the hurt he received in his foote, by one of *Hercules* his arrowes that fell from his owne hand thereon, in overlooking them, when hee received *Hercules* as his gueſt, and therefore of ſome was called *Chironium*. The firſt is called of all writers *Centaurium magnum* or *majus*, and *vulgare* of ſome, as a difference from the others. It hath beene in the former ages of the world (yet long ſince *Galen* his time, for many yeares, and yet continueth in many parts) called *Rhaponticum*, and uſed in the ſtead thereof in all thoſe medicines, that the ancients appoint *Rhaponticum* to be put, which is an errour growne ſo old by cuſtome, that many obſtinately perſiſt therein, becauſe they have received it from their elders, but learning and diligence in reading and ſcanning the writings of the ancient authors, hath not onely diſcuſſed this opinion, but many others alſo; for as I have ſhewed before in the ſecond Claſſis, in the Chapter of *Rubarbe*, *Dioſcorides* ſaith that the *Rhaponticum* is a roote like unto the roote of the great Centory; how then can it be the ſame, when it is but like it, and although the roote of this Centory be yellowiſh, which encreaſed their error, yet will it not colour the ſpittle like unto Saffron. *Braſavolus* in his time, did thinke that thoſe rootes called *Rhaponticum* in the Apothecaries ſhops, were not the rootes of this great Centory; whom *Matthiolus* contradicteth, ſhewing them to be the ſame. Some alſo as *Matthiolus* ſaith, did in his time take the *Lyſimachia purpurea*, to be *Centaurim magnum*. The *Arabians*, *Meſues*, *Avicen*, and *Serapio*, have much confounded the Centories, both the greater and the leſſer together, giving both the face and qualities of the one unto the other, and *Pliny* alſo in his 25. Booke, and 6. Chapter runneth into the ſame error with them, who although he agreeth with *Dioſcorides* in the deſcription of it, yet ſaith it hath a certaine bitterneſſe in it, which is not found in this greater but the leſſer kinde. The ſecond is called by *Cornutus* among his *Canada* plants, *Centaurium foliis Cynaræ*: *Pona* ſaith in the deſcription of the plants growing upon Mount *Baldus*, that the third kind, was called of divers there about *Rheu Baldenſis*, and *Cluſius* ſaith, the *Portugals* where he found it, called it *Raponti*. *Bauhinus* ſaith, that the laſt he received from out of the garden at *Padoa*, by the name of *Rhaponticum Luſitanicum*.

The Vertues.

The roote of the great Centory ſaith *Matthiolus* being ſteeped in wine, or the powder thereof given in wine, is with great good ſucceſſe and profit, uſed for thoſe that are fallen into a dropſie, or have the jaundiſe, or are troubled with the obſtructions of the liver: two drammes of the rootes beaten to powder, and taken in wine or in water, helpeth thoſe that ſpit blood, or that bleede much at the mouth, if they have an ague to take it in water, or elſe in wine, it is likewiſe uſed for ruptures, cramps, and pleuriſies, and for thoſe that have an old or long continued cough, and for thoſe that are ſhort winded, or can hardly draw their breath: it is good alſo to eaſe the griping paines in the belly, and thoſe of the mother: being ſcraped and put up as a peſſary into the mother, it procureth womens courſes, and cauſeth the dead birth to be avoided; the juice thereof uſed in the ſame manner, worketh the ſame effect: ſome copies of *Dioſcorides* have this, it is called *Panacea*, becauſe it helpeth all diſeaſes and ſores, where there is inflammation or bruiſes cauſing it; it helpeth the Strangury or piſſing by droppes, if it be injected, as alſo the ſtone: the decoction or juice of the roote, or a dramme in powder thereof drunke, and the wound waſhed therewith, taketh away all the paine and danger of the bitings or ſtingings of venemous creatures; it helpeth to ſharpen the eyeſight, if it be ſteeped in water and dropped into them. *Galen* in 7. *ſimp.* ſheweth that it hath contrary qualities in it, and therefore worketh contrary effects, the ſharpe taſte ſhewing an hot quality, whereby it provoketh womens courſes, &c. and the aſtringent a cold groſſe earthly quality, glueing or ſodering the lippes of wounds, and ſtaying the ſpitting of blood; and by all the qualities joyned together, helpeth ruptures, crampes, and the diſeaſes of the Lungs: the ſharpeneſſe procuring evacuation, and the aſtriction, the ſtrengthning of the parts: the whole plant as well herbe, as roote, is very availeable in all ſorts of wounds, or ulcers, to dry, ſoder, cleanſe, and heale them, and therefore is a principall ingredient, or ſhould be in all vulnerary drinkes and injections.

CHAP.

CHAP. II.

Iacea. Knapweede.

THere are a very great many of herbes that beare the name of *Iacea*, which I muſt to avoide confuſion diſtribute into ſeverall orders; that ſo the memory being not confounded, with a promiſcuous multitude, each may be the better underſtood in their ſeverall ranckes.

Iaceæ non Laciniatæ, Knapweedes with whole leaves.

Ordo primus. The firſt ranke or order.

1. *Iacea nigra vulgaris.* Our common Matfellon or Knapweede.

THe common Knapweede hath many long and ſomewhat broad darke greene leaves, riſing from the roote ſomewhat deepely dented about the edges, and ſometimes a little rent or torne on both ſides, in two or three places, and ſomewhat hairy withall, among which riſeth up a ſtrong round ſtalke, foure or five foote high, divided into many ſmall branches; at the toppes whereof ſtand great ſcaly greene heads, and from the middle of them thruſt forth, a number of darke purpliſh red thrums or threds (and ſometimes white but very rarely) which after they are withered and paſt, there is found divers blacke ſeede, lying in a great deale of downe, ſomewhat like unto Thiſtle ſeed, but ſmaller, the roote is white, hard and wooddy, with divers fibres annexed thereunto, which periſheth not but abideth with leaves thereon all the Winter, and ſhooting out freſh every Spring.

2. *Iacea nigra anguſtifolia.* Narrowleafed Knapweede.

This Knapweede hath a round rough greene ſtalke, about a foote and a halfe high, whereon are ſet on each ſide, narrow rough, ſhort and ſomewhat hoary greene leaves, compaſſing it at the bottome, and divided into ſome other branches above, on each whereof ſtandeth a ſcaly whitiſh greene head, out of the middle whereof riſe many ſmall long threds, like unto the former, but ſmaller, and of a pale reddiſh colour; after which followeth ſmall blacke ſeede like the other: the roote is blackiſh and parted into many ſmall fibres. Of this ſort alſo there is one, whoſe ſtalke and leaves are longer, ſmooth, and all hoary ſoft and woolly.

3. *Iacea nigra humilis.* The ſmaller dwarfe Knapweede.

This low Knapweede hath ſmall weake and round hoary ſtalkes, about a foote high, bending to the ground

1. *Iacea nigra vulgaris.*
The common wild Knapweede.

6. *Iacea Auſtriaca latifolia villoſo capite.*
The greater hairy headed Knapweede.

with

with leaves thereon, of an inch in breadth, and two in length, not divided or dented about the edges at all, but being a little rough and hoary, as it were thereabouts, compaſſing the ſtalkes at the bottome; at the toppes whereof ſtand ſuch like ſcaly heads, as in the others, with purpliſh threds or thrummes riſing thereout, as in the reſt.

4. *Iacea montana Auſtriaca major.* The greater mountaine *Hungarian* Knapweede.

This greater mountaine Knapweede, is very like unto the former common wilde kinde, being ſomewhat broad and long, dented about the edges, and rough and hairy alſo, and of a darke greene colour, but thoſe that grow upon the ſtraked ſtalkes, are ſtill up higher ſmaller, and more cut in on the edges: the heads that ſtand at the toppes of the ſtalkes, are not rough or hairy, but ſmooth and ſcaly, crackling if they be lightly touched, brow-niſh upward and whitiſh lower: the flowers conſiſt of many purple whitiſh leaves, cut in the ends into five ſlits or diviſions, like as thoſe of the *Cyanus*, with many purpliſh long threds in the middle, and a purple ſtile in the middle of them, beſprinkled at the head, with a mealely whiteneſſe: the ſeede that followeth is like unto the other, but ſomewhat larger: the roote alſo is blackiſh and ſtringy like the former, and abideth as the reſt doe.

5. *Iacea montana Auſtriaca minor.* The leſſer mountaine *Hungarian* Knapweede.

The leſſer *Hungarian* kinde is in moſt things like the laſt, but that it groweth lower, and the leaves and ſtalkes are nothing ſo hairy and rough, but ſmooth and hoary; the flowers alſo are of a paler purple colour, and the ſeede is not blacke, but of a whitiſh gray or aſh colour.

6 *Iacea Auſtriaca latifolia villoſo capite.* The greater hairy headed Knapweepe.

This greater hairy headed Knapweede, hath many long and broad leaves, larger than any of the former, ſofter and whiter alſo, ſomewhat, but not much dented about the edges, of a certaine clammy or gummy taſte. *Io. Thalius* ſaith it hath both ſharpeneſſe in taſte, and tenuitie of parts, ſo that he maketh it hot and drie in the ſecond degree, not without much bitterneſſe; from among which riſe up divers cornered or ſtraked ſtalkes, about two foote high, branched forth at the toppes, whereon ſtand uſually three or foure heads cloſe together, and ſome times but one; whoſe ſcales end in ſuch ſmall whitiſh crooked tangling threds, that they ſeeme like a net, caſt over the heads, out of which ſtart purple flowers like the fift, but larger: the ſeede is not blacke but grayiſh like the laſt.

7. *Iacea anguſtifolia Auſtriaca flore albo.* The white flowred Knapweede of *Auſtria*.

This other Knapweede differeth not from the laſt in any thing, but in the flower which is wholly white, and the ſeede a little grayer.

8. *Iacea anguſtifolia Auſtriaca villoſo capite.* The leſſer hairy headed Knapweede.

This leſſer kinde differeth not from the ſixth, onely in that it is lower, and the leaves narrower, the heades are netted like it but hairy withall; the flowers are purple, and the ſeede blacke, and not gray like it.

The Place.

The firſt groweth with us in moſt fieldes and medowes, and about their borders and hedges, and in many waſt groundes alſo, almoſt every where; the ſecond groweth about *Mompeliar* and *Padoa* alſo: the third in *Auſtria* neare unto Saint *Hippolitus*; all the reſt on the hills in *Hungary* and *Auſtria*, and in the paſture grounds upon them.

The Time.

They all flower in *Iune* and *Iuly*, and in *Auguſt* ſometimes: the ſeede is ripe ſoone after.

The Names.

The ancient Greeke or Latine Authors, have not mentioned this kinde of herbe in any of their Writings, as farre as can hitherto be imagined, and therefore wanteth a Greeke name, whereby it may be called: this latter age likewiſe, hath ſcarſe found a fit name, whereby to call it, yet all doe agree it is a kinde of *Scabions*, and therefore *Tragus* maketh it his fourth kinde of *Scabions*. *Geſner in hortis Germaniæ*, taketh it for a kinde of great Centory of the Medow, and further thinketh it to be that plant, that *Scaliger* calleth *Gethya nigra*. *Thalius in Harcynia ſylva*, calleth it *Cyanus ſylveſtris anguſtifolius*: but generally it is called *Iacea, ſic dictum ut Pena & Lobelius volunt a Ianthino-colore florum*, and *nigra*, as a diſtinction, both from the *Iacea alba Monſp.* of *Pena* and *Lobel*, which they in their *Adverſaria* call *Ocimoides, ſive Ocimaſtrum*; and from the Panſie, which of ſome is alſo called *Iacea*, or *Viola tricolor*: ſome alſo would make it a kinde of *Stæbe*. Many likewiſe call it *Matrefillon*, but very corruptly from *Aphylanthes, quaſi* ἀφύλλὸς ἀνθὸς as ſome would call it, becauſe the flowers are without leaves, being nothing in a manner but threds and thrummes. The firſt is called *Iacea nigra* of divers, and by *Bauhinus Iacea nigra pratenſis latifolia*, and doubteth whether it be not *Solidago Saraſenica altera* of *Lonicerus*: the ſecond is called by him alſo *Iacea nigra anguſtifolia, vel Lithoſpermi arvenſis folijs*: the third he calleth likewiſe *Iacea integrifolia humilis*. The fourth and fift *Cluſius* firſt made known to the world, as it is thought, and called them *Iacea ſquammato capite montana prima & ſecunda*, or *major & minor*: the ſixt *Cluſius* alſo calleth *Lacea Auſtriaca villoſo capite elatior*. *Thalius in Harcynia ſylva*, calleth it *Cyanus ſylveſtris montanus integrifolius*, & ſaith it might be called *Cynogloſſophyllos* from the forme of the leaves. *Bauhinus* calleth it *Jacea latifolia capite hirſuto*: the ſeventh *Bauhinus* ſaith, is a ſpecies of the former, varying onely in the flower, and therefore calleth it *Iacea alba hirſuto capite*, which he ſaith Dr. *Furerus* of *Northuſa*, ſent unto him by the name of *Iacea Auſtriaca major villoſo capite flore albo*: the laſt *Cluſius* calleth *Iacea montana villoſo capite humilis*, and *Bauhinus Iacea anguſtifolia capite hirſuto*: we call it in *Engliſh* Bullweede, and Knapweede, as alſo Matfellon.

The Vertues.

This Knapweede being ſo neare of kindred unto the *Scabions*, are in ſome part equall to them in their properties: for being of an aſtringent and drying taſte, it thereby helpeth to ſtay fluxes, both of bloud at the mouth, noſe, or other outward parts, and thoſe veines that are inwardly broken, or inward wounds, as alſo the fluxes of the belly and of the ſtomacke, provoking caſtings; it ſtaieth likewiſe the diſtillations of thinne and ſharpe humours from the head, upon the ſtomacke and lunges: it is good alſo for thoſe that are bruiſed by any falls, beatings and other caſualties: it is very profitable for them likewiſe that are burſten, and have the rupture, by drinking the decoction of the herbe and rootes in wine, and applying the ſame outwardly to the place: it is ſingular good in all ſorts, of running and cankarous ſorts and fiſtulous alſo, drying vp the moiſture, and healing them up gently without any ſharpeneſſe or biting: it doth the like alſo in the running ſores and ſcabbes of the head or other parts; it is of eſpeciall uſe for the ſoreneſſe of the throat, the ſwellings of the *Vvula* and jawes, it is

alſo excellent good, for all greene wounds, to ſtay the bleeding and to cloſe the lippes of the wounds together.

CHAP. III.

Iaceæ non ſpinoſæ Laciniatæ. Knapweedes with divided or torne leaves and without prickly heads.

1. *Iacea nigra vulgaris Laciniata.* The other common wilde Knapweede.

THis other wild Knapweede that commonly groweth with us among corne very much, as well as in the Meades, groweth with greater and taller ſtalkes, the leaves both below and above upon them, are much divided on both ſides, even to the middle ribbe, almoſt like the great *Scabions* of *Matthiolus* but of a darke greene colour, and as rough or rougher, then the former firſt or common kinde, the ſcaly heades on the toppes of the branches are greater, and the flowers larger, and of a deeper red colour; the ſeede is like the other, and ſo are the rootes, blackiſh and hard with many fibres.

2. *Iacea Cretica.* The Knapweede of *Candy*.

This *Candy* Knapweede hath many leaves lying on the ground, very much cut in on both ſides of them, unto the middle ribbe, and each of thoſe againe cut into other ſmaller peeces; from among which riſe up creſted hard ſtalkes two foote high, whereon are ſet at ſeverall joints, leſſer and leſſe divided leaves than thoſe below; the toppe of the ſtalke is ſevered into ſundry ſmall branches, with every one of them, a ſcaly head on them, thruſting forth the flower compoſed of many long threds of a purpliſh, and ſometimes of a white colour, each of them much jagged at the ends, with a pale ſtile or pointell in the middle of them, which being paſt, the ſeede lieth in the like downy matter, and is not unlike the former: the roote is thicke and ſomewhat great, with fibres thereat.

3. *Iacea montana Narbonenſis.* The *French* mountaine Knapweede.

This *French* Knapweede hath divers long leaves, very much divided on both ſides, into other ſmall long, and narrow ones, but they little or nothing againe divided, of a light greene colour on the upperſide, and hoary white underneath, and a little rough or hard withall, ſomewhat like unto the yellow Knapweede with prickly heades, among which riſeth up a round ſtalk, ſomewhat rough alſo, about a foote high, without many branches, but bearing three or foure ſcaly heads at the toppes, with each of them, a long narrow divided leafe at the foote, with divers purple threds in the middle, ſmelling ſweete; after which commeth the ſeede, not unlike the reſt but leſſer: the roote is long and ſlender and of a bitter taſte.

4. *Iacea montana candidiſſima.* The hoary white mountaine Knapweede.

This hoary white Knapweede, ſendeth forth, from a thicke wooddy roote, divers winged leaves lying upon

3. *Iacea montana Narbonenſis.*
The *French* mountaine Knapweede.

4. *Iacea montana candidiſſima.*
The hoary white mountaine Knapweede.

the

the ground round about it, very much rent or torne on both ſides into many ſmall leaves, which are each of them deepely dented on the edges, ſomewhat like unto the leaves of *Stæbe* or jagged *Scabions*; all covered over, with a hoary white cotten or wooll, or as it were ſprinkled with flower or meale; from whence riſeth up a creſted white hoary ſtalke, about a foot or a cubite high, ſcarſe having any leaves thereon to the top, where it beareth only two or three ſcaly heads like the others with purple threads riſing out of the middle of them: the ſeede is like the reſt.

5. *Iacea humilis Hieracij folio.* Low Knapweede with torne leaves.

This ſmall Knapweede hath many ſmall and narrow long leaves, unevenly cut in or gaſhed on the edges, but blunt or ſomewhat round at the ends of every diviſion, as at the point end alſo, from among which riſe up weake ſtalkes, not able to ſtand upright, but leane downe to the ground, of about a foote high, with ſome ſmaller leaves on them; and at the toppes ſmall ſcaly heades, like unto the others, out of which thruſteth the flower, very like unto the *Cyanus* or Corne-flower, but of a whitiſh blew purple colour, ſomewhat obſcure or ſullen, and ſometimes white, the ſeede that followeth is not unlike the reſt: the roote is thicke and long.

6. *Iacea pumila Narbonenſis.*
Pineapple headed Knapweede.

6 Iacea alia pumila Narbonenſis.

The Pineapple headed Thiſtle or Knapweede.

This ſmall *French* plant groweth ſometimes in the naturall places, without any ſtalke, bearng his Cone or Pineapple-like head, ſo neare the ground, that ſcarſe any part of a ſtalke can be ſeene under it, and ſometimes, and in the ſame grounds alſo, it will beare a round hollow ſtalke, of an handbreadth or two, or a foote high, having divers leaves thereon, cut on both ſides, into many narrow ſhort peeces, greene on the upperſide and hoary underneath: at the toppe of the ſtalke ſtandeth only one large round and long great head, bigger than beſeemeth the ſmallneſſe of the plant, reſembling a Cone or Pine apple, delicately ſet with ſcales, blackiſh at the toppes, and forked or cut into two or three notches at the end, and bright ſhining white fromthence to the bottome of them; from the middle whereof riſeth up divers purple threds, as in the other ſorts, after which come ſmall ſeeds wrapped in much down, as the reſt are, and like unto the former ſmall Knapweedes, but blackiſh: the roote is blackiſh on the outſide, and whitiſh within, of the bigneſſe of ones little finger.

7. *Iacea Laciniata alba.*
Iagged white Knapweede.

7. *Iacea Liciniata alba.*
Iagged white Knapweede.

This white Knapweede hath the ſtalke ſet with many very much jagged leaves, from the bottome branching forth on all ſides, with leſſer & leſſe jagged leaves up to the tops, where on the ſeverall ſmall ſtalkes ſtand ſuch like ſcaly heads as the other before have, but with fine white threds riſing out of them: the roote is long and threddy, and ſpreadeth ſomewhat under ground.

8 *Iacea montana minima lutea.*
Small yellow mountaine Knapweede.

This mountaine Knapweede, hath divers leaves next the roote, about three inches long, cut into many diviſions on both ſides, and each of them againe into ſmaller, but ſomewhat thicke and fleſhie, ſmooth alſo, but ending in a ſharpe point: the ſtalke is ſmall ſcarſe a foote high, bearing a greater ſcaly head, then the ſmallneſſe of the plant ſhould ſeeme to beare, with a gold-yellow flower in the middle, having many upright threds in the middle, and the outward leaves, lying downewards and compaſſing them: after which come ſmall ſeede, wrapped in downe like others, but ſmaller: the roote is ſomewhat thicke, hairy at the head, and parted into fibres.

The Place.

The firſt, as I ſaid groweth in many places of this land, among corne as well as in other fields, eſpecially about *Coventry*: the ſecond groweth in *Candy*, from whence the ſeede being ſent, hath ſprung in divers parts: the third groweth upon the hills of *Caſtrum novum*, neare *Mompelier*: the fourth neare *Capua* in *Italy*; the fift about *Mompelier* alſo, in the borders of fields; the ſixt there alſo, but among the *Ciſtus* and skarlet Oakes; the ſeventh is found in ſundry places of our owne land; the laſt, as *Fabius Columna* ſaith on the hills *Æquicoli* in *Naples*.

The Time.

The firſt five ſorts flower in Sommer, and their ſeede ripeneth ſhortly after, but the two laſt flower not untill *September* in their naturall places.

The Names.

Divers would referre ſome one or other of theſe *Iacea's*, either going before or following after, unto *Hyoſciris* or *Hyoſiris* of *Pliny*, (*quaſi Iovis Seris* as *Pena* ſaith) whereof he maketh mention in his 27. Booke, and 11. Chapter, which he ſaith is like unto *Seris* or *Intibum Endive*, or *Succory*, but leſſe and rough in handling, and good for wounds; of which ſhort deſcription it is hard to determine that *Pliny* meant this plant, for if *Hyoſciris* be a kinde of *Succory*, or belonging to that Tribe, as the name aforeſaid ſhould declare, this cannot be it, for none of the *Succoryes*, or of that ſtocke are found availeable for wounds as theſe are. The firſt here ſet downe, is the *Iacea major* of *Lobel*, the ſixt *Iacea* of *Cluſius*, which he calleth *montana hirſuto capite*, as *Camerarius* doth; and by *Bauhinus Iacea nigra laciniata*. The ſecond *Cluſius* calleth *Iacea ſquammato capite Cretica*, and *Bauhinus Iacea lacinata ſquammata*. The third is called by *Lobel*, *Iacea montana Narbonenſis*, by *Tabermontanus Iacea muſcata & quinta*, and by *Bauhinus Iacea montane incana odora*. The fourth is ſo called by *Bauhinus*, as it is in the title, which he called both in his *Phytopinax*, and in his *Matthiolus Iacea montana Laciniata*. The fifth is called by *Lobel Iacea pumila humilis ſerpens*, *&c.* by *Lugdunenſis Iacea humilis Hieratij folio*; and by *Bauhinus Iacea humilis alba Hieracij folio*. The ſixth is called by *Lobel* and *Pena* in their *Adverſaria*, *Iacea montana*, and *Carduus pineus Narbonenſium*, and thinke it alſo to be the *Chamæleon non aculeatus* of *Theophraſtus*, and by *Camerarius* in *horto Iacea alia pumila ſive nana*, It is very likely to be that *Iacea*, that *Lugdunenſis* calleth *montana Acanophor*, or very like unto it; and by *Bauhinus Iacea montana incana capite pini*. The ſeaventh is mentioned by *Gerard* only as I thinke. The laſt *Fabius Columna* calleth *Iacea montana minima tenuifolia*, but *Bauhinus* calleth it *Iacea laciniata lutea*.

The Vertues.

The firſt of theſe eſpecially, is equall in property with any of the other Knapweedes, both for inward and outward diſeaſes, and therefore whatſoever is ſaid of any of them, may be effectually found herein, the reſt of them that are ſet downe in this Chapter, are in ſome ſort like unto it, although there is no certaine author, hath appropriated them in ſuch manner as the former.

CHAP. IV.

Iaceæ Laciniatæ capitulis ſpinoſis. Thorny headed Knapweedes.

1. *Iacea lutea capitulis ſpinoſis.* Yellow Knapweede with prickly heads.

THis yellow Knapweede hath a few leaves next the ground, much rent or torne on the edges into many unequall parts, ſome bigger and others leſſer, of a grayiſh or overworne greene colour, and of a little acide or ſower taſte, among which riſeth up a ſtalke about two or three foote high branched forth into ſome few, but not into very many branches, ſet with ſome ſmaller and more divided leaves on them, and at the foote of the branches; the toppes of the branches and ſtalkes are each of them furniſhed with a great ſcaly head, ſet round about with ſmall and ſharpe white prickles, and out of the middle thereof many threds, of a pale but ſullen yellow colour, which abide in flower a good while, and when they are paſt, the ſeede is wrapped in a deale of white flockye or downy matter, of a whitiſh or aſh colour, the roote is long and white, and as ſweete almoſt as the roote of *Eringus* or Sea Holly, but creepeth very much and farre underground, ſpringing up againe in divers places. This in the hotter Countryes yeeldeth forth among the flowers, a ſmall reddiſh graine like unto *Gum Tragacant*, but I could never obſerve it in our land.

2. *Iacea lutea ſpinoſa Apula.* The thorny headed Knapweed of *Naples*.

This yellow Knapweede of *Naples*, is in moſt things ſo like the former yellow, that if it be not the ſame, it differeth but little from it, which conſiſteth chiefly in theſe things, the roote is wooddy, as *Columna* who ſo deſcribeth it ſaith, covered with a rugged barke, whoſe head hath many blackiſh haires, as the ribbes and veines of the laſt yeares leaves, the firſt leaves that ſpring up are ſmooth and whole, like unto a Docke, but thoſe that follow after are divided into many parts, like unto Radiſh leaves, but larger and ſomewhat like unto the great Centory leaves: the creſted or ſtraked ſtalke riſeth to be three foote high, ſomewhat hairy as the latter leaves are, at the head whereof which divideth not it ſelfe into above two or three branches, groweth on every one a ſcaly greene head, the edges and toppes of whoſe ſcales are ſomewhat cut in, and ſet with ſharpe yellowiſh thornes, and many yellowiſh threds comming out of the heades; the ſeed that followeth is white and flat, lying in a purpliſh downe.

3. *Iacea purpurea ſupina capitulis ſpinoſis.* The purple flowred Knapweede, with prickly heads.

This purple Knapweed trayleth with his great long branches upon the ground, having whitiſh filmes or skins on each ſide of them, extending to two or three yeards in length, branched forth againe into ſundry other ſtems or ſtalkes, whereon grow large and long leaves, much cut in on the ſides, and of a whitiſh greene colour; at the ends of the branches, ſtand larger ſcaly heads then the former, and greene, with cruell ſharpe thornes or prickes upon them, ready to pierce their legges that improvidently paſſe by it, out of the middle whereof ſtart forth many purple threds, and in them after the flower is paſt, ſmall whitiſh ſeede, little bigger then the ſeede of *Cyanus* or the Bottles, of ſome called the Corne flower, the roote is very great, thicke, white and fleſhy, ſpreading divers great and long branches, but not creeping within the ground as the former doth.

4. *Iacea montana purpurea echinato capite.* The purple mountaine thorny headed Knapweede.

This mountaine Knapweede of *Auſtria*, hath divers ſoft narrow greene leaves, not hard or rough like the common wilde ſorts, more cut in on the edges, and into leſſer parts, ſomewhat like unto the leaves of *Calcitrapa*, or *Carduus ſtellatus*: the ſtalke that riſeth up about two foote high, being creſted or ſtraked, is divided at the toppe into divers branches, ſpreading in breadth more then in length, with many long ſcaly heads, here and there ſet thereon, the toppes or end of whoſe ſcales end in ſmall prickes, but not ſo long and ſharpe as thoſe of the foreſaid thiſtle, and more forked or divided; the flowers whereof are purple threds, like the other Knapweedes;

weedes; the roote thrusteth downe deepe into the ground, like as that Thistle doth, with many small fibres hanging thereat.

5. *Iacea flore albo capite longis aculeis spinoso.* The white thorny headed Knapweed.

This prickly Knapweede sendeth forth a rough hoary stalke, about two foote high, whose first leaves at the bottome are set with thicke white soft haires, but the rest that follow are somewhat long, and two inches broad, thicke, rough, and deepely dented about the edges, and long also, cut into many peeces with white veines running through them, at the toppes of the branches stand the heads, made of many scales, sharpe up to the toppe, like unto a Pineapple, the ends of whose scales are long, straight, sharpe yellowish thornes, and the edges of them, set with white haires like bristles; from the middle of the head starteth up many long whitish leaves, divided or cut in at the ends: the seede is like to that of the Spanish Saffron, but greater then the ordinary: the roote is white and brittle, easie to be broken, made of many strings or thicke fibres, foulding one within another, yet covered with a browniſh skinne or barke.

1. *Iacea lutea capitulis spinosis.*
Yellow Knapweede with prickly heads.

6. *Iacea laciniata Sonchi folio.*
Thorny Knapweede with Southistle leaves.

The leaves that first shoote forth of this Knapweede, are very variable, for some of them are round, standing upon long footestalkes, others afterwards are more and more gashed on the edges, and those especially upon the branches, much more divided, and are so hard and rigid, that if they be a little bowed or foulded together, they will breake with a noyse or cracke, the stalke for the most part is round, and standeth in part upright, but being loaden with heads, bendeth downe to the ground, divided into sundry branches, and set with scaly heads, whose points being greene at the first, are purplish afterwards, and on every of them seaven small thornes, set together on the one side, somewhat like an halfe starre, the middle one being the largest and the longest: the flower after a long time sheweth it selfe, to consist of many long and hollow threds, of an excellent purple colour, whose toppes are broad and parted into some dents, the bottome being very small, narrow and whitish, the broad cut open endsof the flowers are of the deepest purple or red colour, the seed is small gray and long, like unto thoseof the *Cyanus*, or the blew Bottle; the roote is long and threddy, covered with a browniſh skinne or barke, and very brittle withall, this doth somewhat resemble the *Iacea marina Batica* following.

9 *Iaceæ marinæ Beticæ capitulum.*
The head of the Spanish Sea Knapweede.

7. *Iacea montana incana Laciniata capitulis hispidis.*
Hoary mountaine Knapweede.

This small Knapweede hath a round hoary stalke, halfe a foote high, with many hoary, rough, or prickly narrow and long leaves, somewhat torne on the edges at the foote or bottome thereof, but those that rise up with the stalke, are deeper cut in, and the ends sharpe and prickly, at the toppe whereof, which is sometime divided, standeth a small head, composed of prickly scales, whose ends are crooked threds; the flower is purple like the common sort, but much lesser, the roote reddish and threddy.

8. *Iacea tomentoso capitulo spinoso.*
The woolly white Knapweede.

This woolly Knapweede, hath a white woolly stalke, scarse a foote high, but divided into branches from the very bottome, having short and narrow leaves thereon, cut or divided into three, or five or seaven parts, or peeces, somewhat round pointed, so white and woolly, that it seemeth as if it were all strowed over with meale, the small heades at the toppes of the branches are composed of many scales, ending in sharpe reddish thornes; what flower it bore was not observed.

9. *Iacea marinæ Batica.* The Spanish Sea Knapweede.

This Spanish Knapweede hath many long narrow leaves, unevenly dented or waved on the edges, thicke fleshy and brittle, with a little hairinesse, and of an overworne darke greene colour, among which rise low weake stalkes with such like leaves as grow below but smaller, bearing at the toppe but very few flowers, of a bright reddish purple colour, like in forme unto the Corne flowers, but much larger, with many threds or thrummes in the middle, of the same colour, standing up higher then any of the former, which riseth out of a scaly great head, set all over with small sharpe (but harmelesse) white prickes many growing together; the seedes are blackish like the Knapweedes but larger: the roote is great and thicke growing downe deepe, fleshy and full of a slimy juice easie to be broken, blackish without, whitish within and enduring long.

10. *Iacea Babylonica.* The great prickly Knapweede of *Babylon.*

Becauſe we cannot yet give you a full deſcription of this plant, take for the preſent, ſo much thereof, as hath come to our knowledge; for a leafe or two onely being ſent, ſeemed upon the view thereof, like unto a leafe of the *Acanthium*, the White-way, or Cotten Thiſtle, being about a foote and a halfe long, and more than an hand breadth broad, in the middle thereof; ſomewhat hoary and rough in handling, compaſſed all about the edges with ſmall ſharpe prickles, having at the bottome of the leafe ſome torne peeces, on each ſide thereof, three or foure inches long, which growing ſmall to the point, ended in a pricke: the middle ribbe being ſomewhat great and rough, from whence many veines ranne through the leafe. Thus much and no more, wee can yet ſay thereof.

The Place.

The firſt groweth in many places about *Salamanca* in *Spaine*, as *Cluſius* ſaith, and about *Mompelier* as *Lobel* ſaith: the ſecond in *Naples* as *Columna* ſaith: the the third in *Spaine* alſo not farre from the ſea ſide: the fourth at the foote of certaine mountaines in *Auſtria* and *Styria* as *Cluſius* ſaith: the fift in ſome other parts of *Spaine*: the ſixt by the ſea ſide in *Spaine*, about *Porta Sancta Maria*, and *Cales*: the ſeventh on the mount *Calcar* by *Mompelier*: the eight by *Murena* in *Spaine*: the ninth about *Cales* alſo: the laſt about *Babylon*, as the name ſhould intimate, but grew in the garden of *Signior Contarini*, a *Clariſſimo* of *Venice*.

The Time.

They doe all flower in the Sommer, ſome earlier or later than others, and their ſeede is ripe accordingly, onely the ſixth is the lateſt.

The Names.

Cluſius calleth the firſt *Iacea luteo flore ſive Carduus muricatus luteo flore*; *Lobel* and others call it, *Iacea lutea major*: yet in his *Icones* and Obſervations uſeth but one figure, for *Iacea lutea*, which he ſaith is *Cardui ſtellati varietas*, and for *Carduus ſtellatus ſeu Calcitrapa altera*, whereunto in the deſcription he giveth purple flowers. *Lugdunenſis* hath placed this figure of *Cluſius*, under the title of *Carduus Eriocephalus Ddoonæi.* It is by *Dodonæus* called *Spina Solſtitialis altera*; by *Lobel Carduus Stellatus capitulis ſpinoſis ſeu Calcitrapa altera*, as *Bauhinus* ſaith; but I finde it doth better agree with my third ſort here ſet downe, he calleth it *Iacea lutea capite ſpinoſo*: the ſecond *Columna* calleth, *Iacea lævis maxima Centauroides Apula*, and *Bauhinus*, *Iacea lutea ſpinoſa Centauroides*; the third is very probable to be the ſame, that *Cluſius* calleth, *Iacea purpurea Valentina muricato capite*, and *Bauhinus Iacea folijs Seridis candicantibus purpurea*: but I have altered it in the title, his name not fully anſwering the deſcription in all things: the fourth *Cluſius* calleth *Iacea montana echinato capite*, *Dodonæus Cyanoides flos*, whoſe figure *Cluſius* taketh for his *Stæbe Salamantica ſecunda*; *Bauhinus* calleth it *Iacea Cyanoides echinato capite*: the fifth *Bauhinus* calleth *Iacea capite longis aculeis ſpinoſo*: the ſixt he alſo calleth *Iacea laciniata Sonchi folio*, and as I ſaid is very like unto the *Iacea marina Batica*, which is the ninth here: the ſeventh, eight and tenth, have their titles as *Bauhinus* in his *Prodromus* ſetteth them downe: the ninth was ſent among others by *Boel* often before remembred; the laſt is remembred onely by *Bauhinus* in his *Prodromus* to come from *Signior Contarini* his garden.

The Vertues.

All theſe Knapweedes are no doubt of the ſame qualitie with the former, being binding, and many of them glutinous, eſpecially the roote of the ſixt and ninth which as they are of a very clammy juice and ſubſtance, ſo can they not be, but very conſolidative, to knit and ſoder whatſoever needeth ſuch properties.

CHAP. V.

Serratula. Sawēwtor.

THere are ſome other herbes called *Iacea*, by *Lobel* and *Pena*, *Bauhinus* and others, which I darē not ſo doe, not finding them in my judgement worthy to beare that name, and therefore I thought good to joyne this and the next unto them, in ſeverall Chapters as neareſt unto the *Iaceas*, and then thoſe under the name of *Ptarmica*, for that they doe beſt reſemble them alſo, as you ſhall heare when I come unto them. Of this that is neareſt unto the *Iacea*, there is two or three ſorts, differing as well in the colour of the flower, as the leaves, being more or leſſe divided.

1. *Serratula vulgaris flore purpureo.* Common Sawwort with purple flowers.

This Sawwort riſeth up with many of his firſt leaves, ſomewhat broader and longer than thoſe of Betony, and ſharper dented and pointed, all of them ſet upon long foote ſtalkes; but thoſe that riſe up after them are longer and broader, and deepely cut in or gaſhed on the ſides into many parts, and each part finely dented alſo in the ſame manner; from among which ſpring many browniſh ſtalkes, with divers leaves on them, the lowermoſt whereof are divided in the manner aforeſaid, and ſo the higher they grow upon the ſtalkes, the leſſe divided they are unto the toppes, which are branched forth into many parts, bearing ſcaly heads like the former Knapweedes, but nothing ſo great, round and hard, with divers purple threds or thrummes in the middle like unto them, but ſhorter: the ſeede is ſmall and blacke like the *Iacea*, but leſſe lying in downe, which ſheddeth and falleth away: the roote is a buſh of many ſtrings, which encreaſeth into many heads, and ſhoote forth many like leaves, every one of them, whereby it quickly groweth to be a great tuft or buſh. I know ſome doe make foure diſtinctions of thoſe: that is to ſay, one ſort that bringeth all his leaves, dented onely about the edges, and none of them cut in or gaſhed: another ſort, part hath them dented, that is, the firſt leaves, and the reſt that grow upon the ſtalkes, cut in or gaſhed: a third that hath but one or two, of the firſt or loweſt leaves whole, and dented about the edges, all the reſt being divided, ſome more ſome leſſe; and a fourth, that hath all the leaves in generall divided into gaſhes or parts, but yet dented and none whole: which diſtinction of theſe foure ſorts as is ſaid; I confeſſe I could never obſerve to be conſtant in any one plant, more than this, I have here formerly deſcribed, which while it is young, will have many of the loweſt leaves whole, and when it groweth elder, will have many of them divided: but for the firſt ſort, that ſhould have all whole leaves, and none divided, I could never find ſuch a one, and if I, or any other body ſhould, I doe not thinke it would be ſo every yeare.

2. *Serratula*

2. *Serratula flore albo.*
White flowred Sawewort.

This Sawwort is in all things like the former, for I never could obſerve any other diſtinction, but onely that the flower, or the threds in the midddle of the knappes are white, and the heads themſelves, and the ſtalkes, of a freſh greene colour.

3. *Serratula flore rubro.*
Red flowred Sawewort.

This alſo as farre as I could learne or heare, is wholly like the firſt, and not ſingularly to be found by that marke, that it ſhould have all his leaves divided, and none whole, as the fourth ſort, before ſet downe is ſaid to be: the difference betweene them, chiefly conſiſting in the flower, which is of a deeper red colour, which is not eaſily found, or in many places, and is often miſtaken for the other,

The Place.

The firſt is moſt common in the corners of Fields and Wood-ſides, both open and ſhadowed; but that with a white flower groweth at the further end of *Hamſteed* wood, neare unto a rill of water, running by the ſide of a cottage there; as alſo upon *Water downe* Forreſt in *Suſſex*, neare unto the path that leadeth from *Eridge* unto *Ivy Bridge*, by a brooke ſides; the laſt is ſeldome found, and not without good obſervation.

The Time.

They flower in the end of Sommer, and their ſeede ripeneth quickly after.

1. *Serratula vulgaris flore purpureo albo vel rubro,*
Common Sawewort with purple white or red flowers.

The Names.

It is moſt generally now adayes called *Serratula a folijs minutim ſerratis*; yet there be ſome other herbes alſo called by this name, as Betony and Germander, but becauſe each of them is knowne by a more proper name, this of *Serratula* holdeth to this, and is given but *a forma*. Some doe thinke that it was alſo called, (eſpecially by thoſe of *Germany* and *Italy*) *Serratula tinctoria* or *tinctoris*, becauſe it was uſed by them in dying and ſetting of a greene colour; for which purpoſes they in former times, untill they had learned things of better reſpect, uſed it much; but I rather thinke it was called *Tinctoria*, by the miſtaking of *Tragus*, his *Flos Tinctorius*, in *Fol.* 252. which he calleth *Scharten kraut* to be this; for his is the *Aſter Italorum purpureus*, as by his figure under that title may well be perceived; into which errour, *Bauhinus*, as hee ſaith himſelfe, was miſled by *Thalius*, who did ſo thinke it to be, and called it in his *Hercynia ſylva Centauroides, aut Centaurium majus ſylveſtre Germanicum*, untill he found his errour, and reclaimed it in his *Pinax* in the title of *Aſter Atticus cæruleus*, and *Serratula*. I cannot finde any other *Greeke*, *Arabian*, *Italian*, *Spaniſh*, *French*, *German*, or *Low-Dutch* name given it, than according to the *Latine*, as we in *Engliſh* Sawewrot. And for other Latine name, *Thalius* onely, as I before ſaid, accounteth it a kinde of great Centory, and *Lonicerus Solidago Saraſenica*, from the effects.

The Vertues.

It is commended to be ſingular good for ſuch as are bruiſed by any fall, and thereby have ſome veine broken within them; or that are much bruiſed by cruell blowes, and much beating, or otherwiſe much bruiſed by caſualty, for it wonderfully ſtayeth ſuch bleeding, and eaſeth the paine and ſoreneſſe that commeth thereupon, if ſome of the greene or dryed leaves be boyled in white wine, or the powder of them be put into the ſaid wine and drunke. It is no leſſe effectuall alſo, in all inward torments and paines, in the guts and bowels, if both leaves and rootes be boyled in wine and drunke. It is wonderfull good alſo for all wounds, whether they be freſh, to conſolidate and heale them, or being old and filthy ſores, to clenſe and heale them alſo; if the wine of the decoction of the herbe be often uſed to waſh them withall. It is alſo commended for burſtings or ruptures, by often bathing the places, and applying the greene herbe and roote, as a plaiſter outwardly; it is good alſo for the piles, or hemorrhoides, when they grow full of blood and are very painefull, after the applying of leeches, by fomenting the part, with the decoction of the herbe in wine.

CHAP. VI.

Stæbe. Silver Knapweede.

THis herbe *Stæbe*, that is uſually ſo called with all Herbariſts now a dayes (but not that which was ſo formerly of the ancient Writers, & which is quite differing from it) being ſo like unto the *Iaceas*, as none other more; is of divers ſorts, differing both in the leaves and heads of flowers, and ſome other things, as ſhall be preſently ſhewed you.

1. *Stæbe Salamantica prima Cluſij. Cluſius* his firſt *Spaniſh Stæbe.*

This firſt *Spaniſh Stæbe* of *Cluſius*, hath divers large leaves lying on the ground, very much cut in on both ſides, into

into large peeces, but each of them ſet cloſer together than the next, of a ſad greene colour on the upperſide, and ſomewhat whitiſh underneath, very hairy all over, as alſo the ſtraight ſtrong ſtalkes, that riſe up to be three or foure foote high or more, with divers ſuch like divided leaves on them as grow below, but much leſſer, and every one ſharpe at the points, divided at the toppe into ſundry branches, bearing upon long bare or naked ſlender ſtalkes, and ſomewhat long, ſmall ſcaly, ſmooth, round, greene heads, but ſeeming more neatly contrived together, than any of the heads of the former Knapweedes: from the ſmall toppes whereof riſe many fine, purpliſh, or crimſon threds or thrummes, or of a colour betweene both, ſtanding round together, ſomewhat whiter at the bottome of them, which ſo ſtand in the flower neare a moneth before they fade; in the meane while, the ſeede ripeneth in the heads, which is ſmall, not much bigger than the *Cyanus*, and not ſo great as the ordinary Knapweede: the roote is white, long and wooddy, when it is growne above two yeares old, and then oftentimes periſheth in the Winter, elſe it abideth well, and will uſually flower and ſeede two Winters, if they be not too extreme, or they doe not ſtand too much upon the weather.

2. *Stæbe Salamantica ſecunda Cluſij.* *Cluſius* his ſecond *Spaniſh Stæbe.*

This other *Spaniſh Stæbe* of *Cluſius*, hath alſo many divided hairy and ſomewhat hoary leaves, lying on the ground, divided into ſeverall parts on both ſides, but more ſeparate one from another than the former: the ſtalkes likewiſe are hairy, and ſometimes hoary alſo, yet ſtand not ſo upright, but leaning downewards by the weakeneſſe of them, divided into many branches, bearing at the toppes of them, ſomewhat bigger ſcaly heads, from whence ſhoote forth bigger flowers alſo than the former, whoſe outward leaves, are made like thoſe of the *Cyanus* or Corneflower, of a faire purpliſh red colour, with ſuch like coloured threds or thrummes in the middle of them, as are in the former, with whitiſh and yellowiſh bottomes: the ſeede that followeth is like the former: the roote hereof is white and long, but laſteth not after ſeede time.

3. *Stæbe Salamantica argentea.* The ſilver headed Knapweede.

This third *Stæbe* of *Cluſius*, hath likewiſe many leaves riſing from the roote, but they are much more divided, and into ſmaller parts than either of the former being more hoary, or of a whiter greene colour than they: the ſtalke in the ſame manner hoary, riſeth as high as the firſt, with thinne cut or divided leaves upon them, ſharpe at the points, but ſmaller and ſmaller up to the toppes, where it is much divided into branches, and bearing at the ends of them, ſcaly greene, but more white edged leaves, ſeeming as if they were ſilvered; out of which come ſmall purple flowers, like the reſt but ſmaller, the ſeede hereof lying in the downie heads as the others doe, are ſomewhat blacker than they, and having each an hairy toppe on them: the roote is ſomewhat thicke and long, and abideth ſometimes after ſeed time.

4. *Stæbe Auſtriaca Elatior.* The greater *Stæbe* of *Auſtria.*

This *Stæbe* of *Auſtria* differeth neither in forme of leaves nor height in growing from the laſt; neither in the

1. *Stæbe Salamantica prima Cluſij.* *Cluſius* his firſt *Spaniſh Stæbe.*

2. *Stæbe Salamantica ſecunda Cluſij.* *Cluſius* his ſecond *Spaniſh Stæbe.*

flower,

3 *Stæbe Salamantica tertia Cluſij.*
Cluſius his third *Spaniſh Stæbe.*

8. *Stæbe ſpinoſa Cretica.*
The thorny *Stæbe* of *Candy.*

7. *Stæbe plantaginis folio.*
Narrow leafed *Stæbe* of *Candy.*

9. *Stæbe fruticoſa latifolia Cretica.* 10. *Fruticoſa anguſtifolia Cretica.*
Broad leafed ſhrubbe *Stæbe* of *Candy*: and narrow leafed.

flower, but in the ſcaly heads, which are not of ſuch a ſhining ſilver like colour, which onely maketh the difference.

5. *Stæbe Auſtriaca humilior.* The leſſer *Stæbe* of *Auſtria.*

This alſo differeth ſo little from the laſt, that it is in a manner onely diſtinguiſhed by the lowneſſe of the growing, and ſlenderneſſe of the ſtalkes, and not in any thing elſe.

6. *Stæbe argentea minor flore albo.* The leſſer ſilver *Stæbe* with a white flower.

There is likewiſe little difference in any other thing in this, from the laſt, more than in the flower, which is altogether made of white threds or thrummes, without any other colour therein.

7. *Stæbe Plantaginis folio.* Narrow leafed *Stæbe* of *Candy.*

This ſmall *Stæbe* of *Candy* hath divers long ſoft fat and narrow leaves lying next the ground a little dented on the edges, but thoſe that grow up with the ſlender handfull long ſtalkes not at all, but reſembling the Ribwort Plantane leaves, and are of a yellowiſh greene colour: the toppes of the ſtalkes are furniſhed with ſmall long huskes or heads, out of which grow yellow flowers, and after them ſmall long ſeede like unto thoſe of *Scabious*: the roote is white and of a fingers thickneſſe.

8. *Stæbe ſpinoſa Cretica.* The Thorny *Stæbe* of *Candy.*

This Thorny *Stæbe* of *Candy* riſeth up at the firſt, with ſmall and long whitiſh greene leaves, very like unto the ſmall Corne flower or Bluebottle, but thoſe that follow, are much longer, and more cut in on both ſides of the leaves, even to the middle ribbe, but the peeces are ſomewhat round pointed: the ſtalkes riſe not high, but are very much branched, even from the very bottome, into many ſlender hoary wooddy twigges, every one ending in a thorne; at ſeverall joynts of theſe branches come forth ſuch like, but leſſe and leſſe divided leaves, and with the leaves come forth in divers places ſmall ſcaly heads, with white flowers ſtarting forth of the middle of them, like unto thoſe of the little *Cyanus* or Corne flower, but never laid open, abiding halfe ſhut or cloſed continually: after which commeth the ſeede which is ſmall and long; the whole plant is of a grayiſh, hoary or aſhcolour, and liveth many yeares in the warmer countries.

9. *Stæbe fruticoſa latifolia Cretica.* The broad leafed ſhrubbe *Stæbe* of *Candy.*

This plant being found growing in *Candy* by *Honorius Bellus*, and the ſeedes thereof ſent by him unto *Cluſius*, without any proper name, but *Pulcherrimus frutex*, as you have it ſet downe in his ſecond Epiſtle to *Cluſius*, which is ſet forth in the end of his Hiſtory of plants; I have thought more fit to joyne with the *Stæbes*, then as *Bauhinus* doth with the *Storax* tree, as if it were a ſpecies thereof, onely becauſe *Pona* in his *Italian Baldus* ſaith, that *Alpinus* did call it, *Cyanus foliis Styracis*; but he himſelfe (I meane *Pona*) there calleth it, *Cyanus fruticoſus foliis Pomi*; but betweene *Cyanus* and *Stæbe*, there is ſmall difference, that it may be referred to which ſoever one pleaſe; for it partaketh of both ſorts, and yet properly cannot be ſaid, to belong to either of them; the deſcription whereof is as followeth. It groweth up with a wooddy ſtemme for ſome diſtance above the ground, and then ſpreadeth forth divers armes or branches, to the height of two or three foote in compaſſe round, whereon grow divers very faire and freſh greene leaves, very delightfull to behold, being ſomewhat long and broad like unto the leaves of the Appletree, as *Bellus* ſaith, being very white underneath almoſt like ſilver; which thereupon ſome have compared them to the Quince-tree leaves, which are whiter on the underſide than the Appletree leaves; and ſome as *Alpinus*, vnto the leaves of the *Storax* tree, which are very like unto thoſe of the Quince tree; but take which you will, the compariſon in part holdeth correſpondent: from theſe armes or greater branches, ſhoote forth other ſmall long and ſlender ones, bearing very ſparſedly the like leaves on them, but leſſer; at the toppes whereof come forth divers long ſcaly heads, longer than any *Stæbe*, *Iacea*, or *Cyanus*, and with looſer ſcales parted with white and pale red colour, divers ſet together as it were in a tuft, in the ſame manner, as it is to be ſeene in the *Saponaria*, Sopewort; or Bruſewort; at the toppes whereof ſtand the flowers, very like for the forme unto the *Cyanus* or Corneflower, but of a pale Orenge colour; which heads after the flowers are paſt doe containe in them ſmall and long ſeede, ſomewhat like Cummin ſeede, but longer, which abide in the heads very long after, not falling away: the roote is hard and wooddy like a ſhrubbe or tree, or ſhrubby tree.

10. *Stæbe fruticoſa anguſtifolia Cretica.* The narrow leafed ſhrubbe *Stæbe* of *Candy.*

This ſhrubbe *Stæbe* in his naturall place riſeth to be three or foure cubits high, with a wooddy ſtemme or trunke covered with a hoary rugged barke, the wood it ſelfe being very hard, & of an evill ſavour being burned: from whence it ſpreadeth many branches on all ſides rugged alſo at the bottome and hoary, but ſmooth at the toppes, ſomewhat thicke ſet with very long and narrow leaves, & ſomewhat like unto thoſe of the Pine tree or rather of Roſemary, but longer and more hoary all other; the greater armes do ſend forth divers ſmaller branches, with the like leaves on them but leſſer and ſhorter, and at the ends of every of them one ſcaly head, from the middle whereof ſhoote forth the flowers compoſed of many purpliſh blew threds like unto a *Cyanus* for the colour, or a *Stæbe* for the manner, but larger than either of both: this plant will ſerve as a hedge buſh, to be cut and trimmed into what forme you pleaſe like unto other buſhes, and will alſo be encreaſed by ſlipping, and abideth with the leaves alwayes upon it, eſpecially in the warmer countries, yet will not abide the cold Winter of our climate without ſome eſpeciall defence: the roote is wooddy and ſpreadeth like a ſhrubbe or buſh.

The Place.

The firſt three ſorts grow in divers places of *Spaine*, but eſpecially about *Salamanca*, as *Cluſius* who firſt ſet them forth ſaith: the fourth and fifth in *Auſtria*, and other parts of *Hungary*: the ſixt is likewiſe thought to grow about thoſe parts: the foure laſt their titles teſtifie to be in *Candy*.

The Time.

They all doe flowēr in the Sommer Moneths of *Iune* and *Iuly*; yet thoſe of *Candy* flowēr latēr, even in the end of *Auguſt* or *September*, where if any earely froſt take them, they wither ſtraight wayes, although in their naturall places, which are the warme countries, they continue many yeares.

The Names.

Although I doe acknowledge, (as I ſaid before) that none of theſe plants are the true *Stæbe* of the ancients, which hath thorny or prickly leaves, as *Gaza* falſely tranſlateth *Theophraſtus*, but ſhould be thornes and prickles growing with the leaves, yet becauſe as *Cluſius* ſaith, the learned Phiſitions of *Salamanca* in *Spaine*, did uſually ſo call the former ſorts and eſteeme of thēm, becauſe the ends of their leaves were ſharpe pointed, which in ſome

part

part as they thought did answer the description of the *Stæbe* of the ancients; as also because those plants may in the judgement of many be referred to the kinde of *Scabions* (but more truely I suppose unto *Iacea*) which of most Phisitions of these later ages, is therefore accounted, called, and used for *Stæbe*; which notwithstanding is an error great and intollerable, in regard *Scabious* is a smooth herbe, without any shew of pricke or thorne thereon which the true *Stæbe* hath, so it is no lesse erronious to transferre the vertues of *Stæbe* to the *Scabious*; for as *Dioscorides* and *Galen* after him doe affirme, *Stæbe* hath so drying and astringent a quality, that it wil stay any flux of humours or bloud in the bowells or belly, as also those of wounds, which I thinke was never found in *Scabious*. But that I may informe you, (which to some may seeme doubtfull) that *Stæbe* hath a prickly stalke, which is neither extent in *Dioscorides* nor *Galens* Coppies: let me shew you it out of *Theophrastus* in his sixt Booke and first Chapter where he numbreth *Phleos*, which as he saith, was also called *Stæbe*, (and not *Phlomn*, whereof hee speaketh in his fourth Booke and eleventh Chapter, among those plants, that grow in watery and moriſh places; the likenesse of which two words, hath deceived many, mistaking them to be one thing,) among those plants, that have a leafe besides the thornes on their stalkes, which sentence *Gaza* (as I said before) translateth, that it hath beside the prickly leafe, another leafe also by it, for *Theophrastus* in the fifth Chapter of the said sixth Booke, doth deny *Phleos*, and *Hippophaes* to have any prickly but a smooth leafe, although in the third Chapter of the same sixth Booke, he seemeth to say, that *Phleos*, *Tribulus*, and *Capparis* have prickly leaves, beside the thorny stalkes, but both of them cannot be true. And herein *Pliny* hath shamefully erred in confounding *Theophrastus*, making *Phleos* and *phleum* to be one thing, and hath beene the cause of many others errours also. *Plutarch* in the life of *Theseus* about the beginning doth name *Stæbe* among the thorny plants, whose words are these; *Menalippi filius Ioxus Ornito socius deducendæ in Caryam Coloniæ fuit unde Ioxides originem traxerunt, quibus mos est patruus, neque Spinis Asparagi, neque Stæbes igne cremari sed honore & cultu prosequi.* In *English* thus, *Ioxus* the sonne of *Menalippus* was joyned with *Ornitus*, to leade forth a colony to *Carya*, from whence the *Ioxides* have their originall, whose Countries custome it is neither to burne the thornes of Asparagus nor of *Stæbe*, but to give them honour and reverence: thus much *Plutarch*. *Ætius* also in his third Booke and one and twentieth Chapter, remembreth *Stæbe*, saying that *Epithymum*, (or more truely *Dodder*) groweth upon it. But now as I have shewed you that the true *Stæbe* is a prickly or thorny plant, and that therefore neither *Scabious* nor this *Stæbe* is it. Let me here also shew you what is the true *Stæbe*, which is indeede worthy the hearing, but that I reserve it to a fitter place, that is among the thorny plants, where it is called *Pimpinella spinosa*, or *Poterion*, but I forbeare any farther to speake thereof in this place. The first of these here set downe, is called by *Clusius* *Stæbe Salamantica prima*, by *Dodonæus* *Aphyllanthes prima*, by *Bauhinus* *Stæbe major foliis Cichoraceis mollibus lanuginosis*. The second is called by *Clusius*, *Stæbes Salamanticæ primæ altera species*, by *Lobel* *Stæbe argentea incana Aldroandi*, by *Dodonæus* *Aphyllanthes tertia*, by *Bauhinus* *Stæbe major foliis Eruca mollibus lanuginosis*. The third is called by *Clusius* *Stæbe Salamantica altera vel tertia*, by *Lobel* *Stæbe argentea Salamantica minor*, by *Dodonæus* *Aphyllantes quarta*, by *Bauhinus* *Stæbe calyculis argenteis*. The fourth is called by *Clusius*, *Stæbe Gallica* and *Austriaca elatior*, by *Bauhinus* *Stæbe major calyculis non splendentibus*. The fifth is called by *Clusius*, *Stæbe Austriaca humilis*, by *Gesner* in *collectione stirpium*, *Centaurij majoris species minor*, and by *Bauhinus* *Stæbe incana Cyano similis tenuifolia*. The sixth is called by *Tabermontanus* and *Gerard*, *Iacea flore albo*, and by *Bauhinus* *Stæbe calyculis argenteis minor*. The seaventh is called by *Alpinus lib. de plantis exoticis* as it is in the title. The eighth is called by *Pona* in his *Italian Baldus*, *Cyanus spinosus Creticus*, and so also by *Alpinus* in *lib. de exoticis plantis*: *Clusius* in his *Auctuarium*, to the other Appendix to his history of plants, calleth it *Stæbe peregrina*, and saith that *Iacobus Plateau*, who sent him a branch of the plant, with the figure thereof drawne, having gathered it in the Garden of the Duke of *Areschote*, in *Bellomonte*, called it *Stæbe spinosa fruticans*. The ninth I have joyned with these *Stæbes* as I said before, rather then with the *Storax* trees as *Bauhinus* doth, calling it *Frutex rotundo argenteo folio Cyani flore*; for *Pona* in the same place above said, calleth it, *Cyanus fruticosus Creticus*, and is the same plant that *Honorius Bellus*, in his second Epistle to *Clusius*, as he saith, could not learne by what name they of *Candy* called it, and therefore he onely called it *Pulcherrimus frutex*. I have as you see, set it and the last with the *Iacea's*, being neareſt in likenesse to them, in regard these have all scaly heads, as the *Iaceas* have; which are not seene in any *Scabions*. The last *Pona* in the description of Mount *Baldus* first called *Stæbe capitata Rosmarini foliis*, but after in his *Italian* booke, he calleth it *Chamæpitys fruticosa Cretica Belli*, and by them of *Candy* called Βεργωξήλια, *id est*, *lignum fœtidum*, and by *Bauhinus* *Iacea fruticans Pini folio*, and is thought to be the *Chamæpence Plinij* of *Anguillara*. The *Spaniards* as *Clusius* saith, call the first by the name *Cabesuela*, *id est*, *capitulum* a little head, and usually make broomes thereof to sweepe their houses, the learned Phisitions there as he saith, use the third sort instead of *Scabious* for all the purposes thereof.

The Vertues.

The most of these sorts, but especially the three first, do come somewhat nigh unto the qualities of *Scabions* and therefore I must referre you thereunto, to know both what remedies may be had from these plants, and in what manner, and to what purpose to be used: for as *Scabions* fitteth the parts whereunto it is applyed, so doe these also.

CHAP. VII.

Ptarmicæ non vulgares. Vnusuall Sneesewort.

HAve here as I promised before, brought to your knowledge those other plants, that comming neereſt unto the *Iacea's* and *Stæbes*, and yet being none of them, were fittest to be entreated of in a Chapter peculiar by themselves; for as I said although *Bauhinus* doth put these two sorts under the title of *Iacea oleæ folio*, and reciteth their authors for them, who are chiefely *Lobel* and *Clusius*, yet I cannot finde by the same authors, as well as by mine owne sight and knowledge, but that they are differing plants, from both *Iacea* and *Stæbe*, but I would not have you conceive, that any of these *Ptarmica's* is that, which groweth wild with us in divers places; for I meane to bring it into that Classis that is fit for it, namely that of hot, sharpe, and biting herbes; the double kinde whereof, I have set forth in my former booke.

1. *Ptarmica*

1. *Ptarmica Austriaca Clusij sive major.* *Clusius* his Sneesewort of *Austria.*

The Sneesewort of *Austria* sendeth forth many leaves from the rootes lying on the ground, being soft and smooth, somewhat long and narrow, greene on the upper side, and hoary on the under, of a little sower rellish or taste; among which riseth up an hoary stalke, about two foote high or better, having divers such like leaves thereon, but lesser, spreading into some few slender branches, with every one for the most part, a small scaly white silver like head on them, from whence spring forth a dozen or foureteene hard, and small long pointed leaves, as a border or pale, about a number of small short thrummes in the middle, almost like as if they were made of parchment, whitish at the first appearing, but afterwards being come to their full maturity, of a most faire bleake blewish purple colour, without any sent to commend it, pleasant onely by the prospect of forme and colour, and by the durability; for being gathered in his perfection, it withereth not, or looseth colour, but abideth in the same colour, without changing for many yeares together, being put into a paper booke, otherwaies being let stand upon the stalkes, they become somewhat browniish, having many small blackish long seedes, lying among a deale of white downe, the roote is hard and blacke with some fibres at it, but perisheth every yeare.

2. *Ptarmica Imperati sive minor.* The smaller Sneesewort of *Spaine* or *Naples.*

This smaller Sneesewort, hath such like long and narrow soft hoary leaves, but not fully so large as the former, the stalke riseth not so high, but is divided into more and more slender hard branches; at the toppes whereof stand such like scaly heads, but not so white or silver like, from whence shoot forth, such like stiffe hard leaves as the pale or border, but neither so large nor so many, being seldome above eight or tenne, neither are they of so faire a blewish purple colour, but of a pale delayed colour, having many thrummes in the middle: the seede that followeth is like the former, and so is the roote, but smaller both of them; and perisheth in the same manner every yeare, this plant being a little rubbed or handled, sendeth forth a reasonable sweete sent, or at least not to be misliked.

The Place.

The first *Matthiolus* saith groweth in *Italy*, and *Clusius* saith he found it in *Austria*, and afterwards in divers parts of *Hungary*, *Lobel* saith it groweth about *Mompelier*, for I suppose his *incana altera lacea*, to be this *Ptarmica*, himselfe also saying that some did so call it, although he describeth it to have rougher leaves. The second we having received the seede from *Italy*, under the name of *Ptarmica Imperati*, have thought good to expresse it, by the same title we received it. *Clusius* in his *Curæ posteriores* saith, the seede was brought out of *Spaine*, that grew with them, and *Lobel* saith of the same plant as I take it, that it came out of *Syria*.

The Time.

They both flower late, that is not untill the beginning of *August* at the soonest, and the seede is not ripe until the middle of *September*.

The Names.

The name πταρμικη in Greeke, signifieth as much as *Sternutamentorium* in Latine, that is, to provoke sneesing,

1. *Ptarmica Austriaca Clusij.*
Clusius his Sneesewort of *Austria.*

2. *Ptarmica Imperati sive minor.*
The smaller Sneesewort of *Spaine* or *Naples.*

which

which *Cluſius* ſaith this doth not, and therefore cannot be *Dioſcorides* his *Ptarmica*, although it doth agree therewith in many other things, neither doth *Matthiolus* acknowledge it for the right *Ptarmica*, although he ſaith that thoſe plants that grow in *Italy* doe provoke Sneeſing. *Cluſius* calleth it *Ptarmica Auſtriaca*, becauſe he firſt found it in *Auſtria*, *Matthiolus Ptarmica altera*: *Lobel* out of doubt meaneth this plant, which he calleth *Iacea incana altera Cyani*, *aut Iaceæ capitulis*, and therefore in my perſwaſion, *Bauhinus* hath not done well, to make it two diſtinct plants, for if he ever ſaw it, he might finde it to differ notably from the *Iacea's*, for which cauſe both *Matthiolus* and *Cluſius* gave them rather the name of *Ptarmica*, to ſhew the variety thereof from *Iacea*. (as it worthily deſerveth) The other is called by *Cluſius* in his *Curæ poſteriores*, *Ptarmicæ Auſtriacæ ſpecies*, and is out of doubt alſo, that plant which *Lobel* in his Obſervations calleth, *Iacea puſilla incana altera folio Oleæ*, which *Bauhinus* alſo maketh to be two diſtinct plants, thus making foure ſorts of theſe two plants, when as *Lobel* in his quotation in the Margent of the ſaid *Iacea* ſaith, it is *Ptarmica herbariorum*, meaning the former *Auſtriaca*, or this, for thereunto it doth moſt properly appertaine.

The Vertues.

Matthiolus ſaith that in *Italy* they uſe it for no other purpoſe, but to make broomes thereof to ſweepe their houſes, *Cluſius* ſaith the women about *Vienna*, who gather herbes abroad, and bring them to the City to ſell, doe call it a *Scabious*, and keeping it dry all the yeare, doe ſell it to the Apothecaries, and others when they need it, to ſerve them for the purpoſes whereunto *Scabious* is appropriate; and further ſaith, that the people thereabouts doe confidently beleeve, that the decoction thereof given to Children, doth very profitably helpe them, when they thinke they are bewitched; (or rather as I doe take it, when ſome grievous paines or torments in their ſtomackes and bowels doe take them, from the crudity of humours therein gathered, by their often feeding of fruites that breed ſuch corruptions;) and although we have not found that it hath beene much uſed in Phiſicke, yet aſſuredly by the judgement of many, it cannot be without ſome of the eſpeciall properties of *Scabious*, or *Iacea* at the leaſt, it doth ſo neerely approach thereunto, both in forme and temperature.

CHAP. VIII.

Cyanus. Blew Bottles.

I Would willingly interpoſe this Chapter of the *Cyani* Blew Bottles, betweene the former plants, and the ſorts of *Scabious* that ſhall follow in the next, both becauſe they have ſcaly heads, which none of the *Scabiouſes* have, and becauſe that divers of the *Iacea's* and *Stœbes* have heads of flowers much reſembling the *Cyani*.

1. *Cyanus major vulgaris.* The greater ordinary blew Bottle.

The greater blew Bottle or Corneflower, (which I therefore call ordinary, becauſe there is a Turky kinde, which is extraordinary) riſeth up with a creſted, or rather winged whitiſh greene ſtalke, about two foote or a yard high, whereon are ſet divers leaves ſomewhat long and broad, without any diviſion or dent on the edges, greene on the upperſide, and grayiſh underneath, each of them compaſſing the ſtalke about, at the lower ends, which is divided at the toppe into a few branches, bearing ſomewhat large ſcaly greene heads, with white or ſilver like edges; from the middle whereof commeth forth a larger flower then in the ſmaller kinde, thinnely or ſparſedly ſet, and of a deeper violet blew colour, in which heads after the flowers are paſt, ſome few white ſeedes are found among the downe, like the leſſer kinde, but ſomewhat bigger and flatter: the roote creepeth under ground, and ſpreadeth divers wayes, ſo that the heads with greene leaves will abide all the winter, which in the other ſorts doe not ſo, but periſh wholly after ſeede time, and doth riſe of it owne ſowing before winter, and ſo abideth greene all the winter, untill the next Spring and Sommer, that it flowreth, ſeedeth, and periſheth againe.

2. *Cyanus minor vulgaris diverſorum colorum.* The ſmall ordinary Corne flower of ſundry colours.

The ſmall ordinary Corneflower is wonderfully diverſified, as I have ſhewed in my former booke, in the colours of the flowers, but not variable in any thing elſe: for the leaves are long and narrower then the former, cut in on the edges ſomewhat deepely, yet ſome more then others of a whitiſh greene colour; the ſtalke riſeth to be three foote high or more, ſet with the like leaves, but ſmaller and leſſe cut in on the ſides, branching forth on all ſides, and bearing at their toppes many greeniſh ſcaly heads, out of which riſe flowers conſiſting of five or ſixe or more long hollow leaves, ſmall at the bottome and opening wide at the brimmes, where they are cut and notched ſomewhat deepely into divers parts, with many ſmall ſhort threds in the middle; the colours of theſe flowers are divers, ſome being of a perfect blew or purple colour, paler or deeper, ſome white or of a bluſh colour, otherwiſe of a ſad or light red or overworne purple, wholly without mixture in the leaves or thrummes; but ſome will be mixed of blew and white or of the other colours, either edged, ſtriped, or ſpotted, the threds in the middle varying likewiſe: after the flowers are paſt, the heads grow full of ſmall hard white ſhining ſeede among the ſhort downe, which eaſily and quickly falleth away, leaving the head flat and empty, the rootes are ſomewhat long and hard periſheth every yeare, but uſually is renued by it owne ſowing. The *Candy* kinde is like hereunto, but more hoary, and the flowers purple, not varying. *Creticus Lanugi-noſus.*

3. *Cyanus floridus odoratus Turcicus ſive Orientalis major & minor.* The Sultans flower a greater and a leſſer.

This ſtranger lately obtained from *Conſtantinople*, where the *Gran Signior* or great Turke as we call him, eſpying it growing abroad, liked it and wore it himſelfe, whereby all his vaſſals held it in great eſteeme; the leaves hereof are not much greener, but larger, and more gaſhed in on the edges; the ſtalkes are a yeard high at the leaſt in the greateſt, and lower in the other, beſet with the like leaves but ſmaller, and branching into ſundry parts, bearing each of them a larger ſcaly head then the former, and bigger in the one then in the other, with ſuch like flowers but larger, conſiſting of eight or nine hollow leaves with wider open brimmes, and ſmall threds in the middle: the circling leaves are of a fine delayed purple or bluſh colour very beautifull and the thicke thrums paler or almoſt white, of ſo exceeding a ſweete ſent, that it ſurpaſſeth the fineſt Civet that is; the ſeede is blackiſh and encloſed in the like downy ſubſtance; the roote periſheth every yeare, the greater of theſe two ſorts ſmelling much better then the other.

1. *Cyanus major vulgaris.*
The great ordinary blew Bottle.

2. *Cyanus minor vulgaris diversorum colorum.*
The small ordinary Corne flower of divers colours.

3. *Cyanus Orientalis major & minor.*
The greater and lesser Orientall Bottle or *Sultans* flower.

5. *Cyanus repens latifolius.*
Broad leafed *French* Corne flower.

4. *Cyanus Bæticus ſupinus.* The *Spaniſh* Corne flower.

This *Spaniſh* kinde hath many ſquare low bending or creeping ſtalkes not ſtanding ſo upright as the former, but branching out more diverſly, ſo that one plant will take up a great deale of ground, the leaves are ſomewhat broader, ſofter, and of a paler greene colour, then of the common ſmall kinde, but not much or deepely gaſhed on the edges; the flowers ſtand in bigger heads alſo, and with foure or five leaves under each, of a light purple or bluſh colour, after which come white ſeed like thereunto alſo, but not ſo plentifully, yet wrapped in a more downy ſubſtance, the roote groweth downe deepe and periſheth likewiſe every yeare as they doe.

5. *Cyanus repens latifolius Lobelij.*
Broad leafed *French* Corne flower.

This *Cyanus* that *Lobel* and *Pena* in their *Adverſaria* have ſet forth, whoſe taſte is very bitter and unpleaſant, hath divers weake hoary and trayling branches not ſtanding upright, about a foote and a halfe high, whereon grow divers hoary leaves, ſomewhat long and narrow, and ſomewhat like unto thoſe of Lavander, but harder in handling, at the top of the ſtalke which is branched forth, grow ſeverall ſcaly heads like unto the other *Cyani*, whoſe flowers are like unto them, but of a ſadder or deader purple colour, then in any of the other ſorts; the roote is about a fingers length.

6. *Cyanus repens anguſtifolius ſive minimus.*
The ſmalleſt Corne flower of *Mompelier*.

This ſmalleſt Corne flower, hath likewiſe divers weake ſlender yet hard hoary and twigged ſtalkes, whereon are ſet divers ſmaller leaves then the laſt, but hoary in the ſame manner; at the toppes of the branched ſtalkes, ſtand many ſcaly heads, much leſſer then any of the ſorts of Corne flowers; from whence grow ſuch like flowers, but of a ſadder or deader colour: the ſeedes are like the ſmaller ordinary kindes, and the roote is ſmall, long and wooddy.

7. *Cyanus Creticus ſpinoſus.*
Prickly Corne flower of *Candy*.

The lower leaves of this Corne flower are jagged and very hoary, but thoſe on the hoary branches of the ſtalkes are leſſe or not at all, they ending in long ſharpe prickes or thornes with ſmall bluſh-coloured flowers like the others ſorts but ſmaller, the roote is long and ſomewhat thicke enduring many yeares.

6. Cyanus minimus repens anguſtifolius.
The ſmalleſt Corne flower of *Mompelier*.

The Place.

The firſt groweth naturally upon ſandy hils in *Germany*, but is uſually cheriſhed elſewhere in Gardens; The ſecond with blew flowers in many corne fieldes of our owne land and ſome of the other colours alſo; The third as is ſaid in *Turkie*, and the fourth in *Spaine*, firſt found and ſent unto us by Doctor *Boel*, who is now reſident at *Liſhborne*. The fifth groweth under the branches of the *Seſeli pratenſis* by *Sella nova* neere unto *Mompelier*, and the ſixt thereabouts alſo, and by *Caſtrum novum* not farre from *Mompelier*, as *Pena* and *Lobel* doe ſet them downe in their *Adverſaria*; the three laſt and the other woolly ſort in *Candy*.

The Time.

They flower and ſeede in the Sommer Moneths when the other doe.

The Names.

It is called κυανος *Cyanus, a floris Cyaneo vel cæruleo colore.* In the Infancy of Herbariſts, *Tragus* who knew not well what to call the firſt, referred it to the *Verbaſca*, and called it *Verbaſculum*, but now it is generally called by all Herbariſts, *Cyanus major*; ſome adde thereunto *hortenſis*, and others *Montanus*, yet *Hermolaus* taketh it to be *Leucoium* of *Dioſcorides*, and *Cæſalpinus* to be a kinde of *Struthium*, whereof *Theophraſtus* maketh mention: *Fabius Columna* judgeth it to be that kinde of *Papaver* which *Theophraſtus* calleth *Heracleum*, and *Lobel* maketh a doubt whether it may not be accounted a ſpecies of *Chondrilla*. The ſecond ſort that groweth in the Corne is called *Flos Frumenti* and *Baptiſecula* or *Blaptiſecula*, of the turning the edges of ſickles, in cutting downe the Corne for *Secula* was taken for a Sickle in ancient time. The third was ſent us out of *Turkie*, by the name of *Ambreboi*, which whether it be a *Turkiſh* or *Arabian* name I know not, the *Turkes* themſelves as I heare, doe generally call it the *Sultans* flower and ſo doe I, but that I adde *odoratus* for the ſweete ſent of the flower. The fourth was ſent by *Boel* under the name of *Iacea Bætica*, but becauſe I finde it better agreeing with *Cyanus* then *Iacea*; I have inſerted it here. The two next ſorts are called *Cyanus ſupinus & repens* by *Lobel* in his *Adverſaria*. The *Candy* kindes are mentioned by *Alpinus* in his Booke *de exoticis*.

The Vertues.

The powder of the dryed leaves of the greater blew Bottle, or Corne flower, is given with good ſucceſſe to thoſe that by ſome fall are much bruiſed, and for them alſo if they have broken a veine inwardly, and voide much blood at the mouth, being taken either in the water of Plantaine, Horſetaile, or the greater Comfrey. It is accounted a helpe or remedy againſt the poyſon of the Scorpion and *Phalangium*, and to reſiſt all other venomes and poyſons. And therefore *Placentius* affirmeth it to be excellent good in all peſtilentiall feavers, and of its owne power, to be powerfull againſt the plague or peſtilence, and all other infectious diſeaſes, either the ſeede or the leaves taken in Wine. The juice is ſingular good to put into freſh or greene wounds, for it doth quickly ſoder

up the lippes of them together; and is no leſſe effectuall alſo to heale all ſuch ulcers and ſores as happen in the mouth: The ſame juice alſo dropped into the eyes, taketh away the heate and inflammations in them: the diſtilled water of the herbe, hath the ſame properties, and may be uſed for all the effects aforeſaid. The leſſer blew Bottle or Corne flower is uſed generally by all our Phiſitions and Apothecaries in the ſtead of the greater when it is not to be had, and is held to be in a manner as effectuall as the greater.

CHAP. IX.

Scabioſa. Scabious.

NOw that we are comē to handle the varieties of the Scabiouſes, they arē ſo many, that I know not well how to marſhall them into any good method or order, yet that I may endeavour it the beſt I can, I thinke it fitteſt to ranke them into foure Orders; that is, firſt, of ſuch ſorts as grow in the Meddowes and Paſture grounds; next of thoſe that grow in the Woods, and upon hills and high grounds: thirdly, of ſuch as beare a round or Globe-like head; and laſtly, of ſuch as beare flowers more ſtarre-like than others. And yet I doubt not, but that although I ſhall endeavour, as neare as I can to ſet every one in their right order; yet ſome of them alſo may be thought as fit for another Order, as that wherein they are ſet; which notwithſtanding take them now in the ſame manner I give you them. And for the *Morſus Diaboli*, or Divells bit, which is another ſort of Scabious, I entend to ſpeake thereof in a Chapter by it ſelfe: yet I muſt leave out thoſe three ſorts I have mentioned in my former Booke wh ch are *Scabioſa flore albo*, *Scabioſa rubra Auſtriaca*; and *Scabioſa Indica flore rubra*: although I give you their figures here againe.

Scabioſæ pratenſes & arvenſes. Thoſe ſorts of Scabious that grow in Meddowes and plowed grounds.

1. *Scabioſa vulgaris pratenſis.* The common field *Scabious*.

THe common field *Scabious* groweth up with many hairy ſoft whitiſh greene leaves, ſome whereof are either not at all jagged, or divided on the edges, or very little, others are much rent and torne on the ſides, and have threds in them, which upon the breaking may be plainely ſeene, and are not in divers other ſorts; from among which riſe up divers round hairy greene ſtalkes, three or foure foote high, with ſuch like hairy greene leaves on them, but more deepely and finely divided, branched forth a little; at the toppes whereof which are naked and bare of leaves for a good ſpace, ſtand round heads of flowers, of a pale blewiſh colour, many ſet together in a head or knoppē, the outermoſt whereof are larger than thoſe inward, with many threds alſo in the middle, ſomewhat flat at the toppe, (and not ſo round Globe-like as the other, which ſhall be deſcribed hereaf-

2. *Scabioſa minor campeſtris.* The leſſer field *Scabious*

4. *Scabioſa Pannonica flore albo.* White *Hungarian Scabious.*

tēr)

Scabiosa flore albo.
White flowred *Scabious.*

6. *Scabiosa æstivalis Clusij.*
Clusius his Sommer *Scabious.*

ter) as the head with seede is likewise; the roote is great, white, and thicke, growing downe deepe into the ground, and abideth many yeares.

2. *Scabiosa minor campestris.* The lesser field *Scabious.*

This lesser sort is like the former almost in all things, but that the leaves are not so large, or deepely jagged, nor the stalkes rise so high, nor the flowers so great or large, yet of the same bleake blewish colour: this may be thought to be the same with the former, differing onely but in the rankenesse of the ground where they grow, but that this is so usually observed to be no greater or of any other forme, although it grow in the same or as ranke ground as the other.

3. *Scabiosa major segetum.* Corne *Scabious.*

This Corne *Scabious* also differeth little from the first, but that it is greater in all respects, the leaves being larger with greater divisions, and some whole leaves with them also: the stalkes are greater and stronger, and the flowers larger, more laid open, and not so closely thrust together, but of the same blewish colour, yet a little more declining to purple: the roote hereof runneth not deepe into the ground, but rather creepeth under the upper crust of the earth.

4. *Scabiosa Pannonica flore albo.* White *Scabious* of *Hungary.*

This great white *Scabious* of *Hungary* hath large stalkes, three foote high at the least, whereon grow at every joint two leaves one against another, very much and finely cut in, and jagged on the edges, more than any of the former sorts of *Scabious*, but those that grow next the ground are broader, softer in handling, and more hairy, and onely dented about the edges and not divided, that one would not thinke them to be the leaves of a *Scabious*: the stalkes are branched and flowers like unto other *Scabiouses*, stand at the toppes of them, but of a pure white colour, and the outermost row of flowers for the most part being twise as large as any of the rest, with white threds in the middle of them tipt with blew: the seede that followeth is long and browne like unto the rest, which falling when it is ripe, springeth a fresh before the Winter, and abideth untill they have seeded againe the next yeare, for the roote perisheth yearely.

5. *Scabiosa minima Ovilla dicta.* Small sheepes *Scabious.*

This small *Scabious* hath divers whitish greene leaves at the ground divided on both side of the long pointed leafe, onely into one division, on each side, making every leafe seeme like the small Sage leafe, called Sage of Vertue, that hath small peeces of leaves like eares on each side thereof; but a little dented about the ends; the small low stalkes are furnished likewise, with such like leaves but lesser, and small blewish flowers or heads on them like unto the other field *Scabious* but lesser.

6 *Scabiosa æstivalis Clusij. Clusius* his Summer *Scabious.*

The stalke hereof being three cubits long beareth long leaves set by couples thereon, which are long and some-

what broad and little rent or torne at the bottome, but dented all the reſt of the leafe: the flowers grow on ſeverall branches at the toppes of a pale blew colour, the roote periſheth every yeare.

7. *Scabioſa arborea Cretica Alpino. Alpinus* his ſhrubbie *Scabious* of *Candy*.

This *Scabious* hath a thicke whitiſh ſtemme next the ground for a ſhaftmont high, from whence riſe ſundry long branches ſet at certaine diſtances, with five, ſixe, ſeven or more leaves at a ſpace, each of them ſomewhat reſembling thoſe of the true Houſeleeke but hoary white; the toppes of the branches have two or three large flowers, ſtanding on ſlender long foote ſtalkes together, like unto the common ſort for the faſhion, but of a delayed or waſh bluſh colour, after which ſucceedeth ſmall ſeede, and is very tender to keepe.

The Place.

The firſt groweth moſt uſually in moſt Medowes of this land, eſpecially about *London* every where. The ſecond groweth likewiſe in ſome of the drie fields about this Citie, but not ſo plentifully as the former. The third groweth both in the grounds where corne is ſtanding, and in thoſe that were formerly ſowne, and now lie fallow, as alſo in the border of ſuch like fields. The fourth *Cluſius* ſaith he found, nigh unto the wall of *Tirnavia* a cittie in the upper *Hungarie*: the fift is found in many drie gravelly and heathy grounds throughout the Realme: the ſixt grew in the low countries as *Cluſius* ſaith of the ſeede he had formerly ſent thither; and the laſt in *Candy*.

The Time.

They all flower in *Iune* and *Iuly*, and ſome abide flowring untill it be late in *Auguſt*, and the ſeede is ripe in the meane time.

The Names.

This herbe is not found to be remembred by any the ancient Greeke or Latine Authors; yet ſome ſome thinke it is that herbe *Ætius* calleth Ψώρα, but becauſe there is nothing but the bare name that is extant in him, without any deſcription, it his hard to ſay it is the ſame; notwithſtanding the Greeke word ſignifieth *Scabies* in Latine. But it tooke the name of *Scabioſa*, either a *foliorum ſcabritie quæ preſertim, primo huic generi convenit*, or rather, and that moſt uſually, *quod Scabiei medetur*: the name is of divers applied, as I ſaid before, to divers herbes, as to the *Iaceas*, *Stæbes*, and others, calling ſome of them *Scabioſa major*, and *altera ſquammatis capitulis*, as *Bauhinus*, and others doe: but as I ſaid before, the heads and flowers of all theſe herbes called *Scabiouſes*, being all ſo neare and like one unto another, and ſo differing from *Iacea*, *Stæbe*, &c. muſt needes ſhew plainely that they ſhould not be ſo confounded, for a novice ſhall hardly underſtand what herbe is meant, by ſuch names as are impoſed on divers of them: the Author of the *Pandects*, is thought to be the firſt that miſtooke *Dioſcorides Stæbe*, to be this *Scabious*, from whence the errour thereof ſoone ſpread among *Phyſitions* in all countries, and continuing ſtill, is hardly to be rooted out againe, *Tam facilis eſt deſcenſus in errorem, & e contra arduus aſcenſus in veritatem. Fabius Columna* in his *Phytobaſanus*, ſeemeth to referre the *Scabioſes* unto *Phyteuma* of *Dioſcorides*; but in his other Booke of rare plants, he declineth to thinke that ſuch ſmall *Valerians*, as he there deſcribeth, becauſe the ſeedes have holes in them, ſhould be the *Phyteuma* of *Dioſcorides*. The *Italians*, *Spaniſh*, *French*, and *Engliſh*, do all follow the Latine name *Scabioſa*, as each Dialect will admit, only the *Germanes* call it *Apoſtem kraut*, *Peſtem knaut*, and *Grinde kraut*. The firſt is called of moſt Writers, either *vulgaris*, or *communis*, either *pratenſis* or *officimarum*: the ſecond is called *Scabioſa media*, and *minor* of divers, and *Columbaria* of *Lobel*, and is *Cluſius* his fift *Scabious* in his Hiſtory of Plants, *Bauhinus* ſetteth it downe for his ſecond ſpecies of *Scabioſa capitulo globoſo*, and yet he nameth the ſame *Scabioſa prima Cluſij* for the ſecond of his *montana*; hereby making that one plant to be two ſeverall kindes, which thing is very frequent with him, in many other things and places, in his *Pinax*, *Prodromus*, and *Matthiolus*: the third is called *Scabioſa campeſtris ſeu ſegetum* of *Lobel*, as alſo *major ſatorum vulgatior*. The fourth is called by *Cluſius*, *Scabioſa Pannonica flore albo*, and is his eight *Scabious* in his Hiſtory of Plants: the fift is that *Scabious*, which we generally throughout the land, doe call ſheepes *Scabious*, called by *Dodonæus Ovilla*, although much differing from his deſcription, which he calleth alſo *media*; and of *Lobel Scabioſa montana omnium minima*, and yet the figures of neither of them are anſwerable to the true herbe: the ſixt *Cluſius* only maketh mention, and *Bauhinus* calleth *Scabioſa fruticans latifolia alba*: the laſt is that which *Alpinus* deſcribeth and pictureth in his Booke *de plantis exoticis*, and is very likely not to be the ſame with *Pona* in his *Italian Baldus* ſetteth forth, in that his is ſet forth to have but one leafe at a place.

Scabioſæ montanæ. Mountaine and wood *Scabiouſes*.

1. *Scabioſa montana maxima.* The greateſt mountaine *Scabious*.

THis great mountaine *Scabious*, which ſome for the largeneſſe thereof, have accounted a great and baſtard kinde of great Centory, hath divers very large winged darke greene leaves, that is very much cut in on both ſides into divers parts to the middle ribbe, and each part finely nicked or dented about the edges, many leaves (eſpecially growing at large in any good ground) being a foote or ſometimes more in length, or moſt commonly neare there unto: from among which riſe up divers hard wooddy ſtalkes ſometimes foure or five foote high, and uſually about three foote high, branching towards the toppes, into ſome other ſmaller ſtemmes; at the toppes of each whereof ſtandeth one large great round, blackiſh greene head, from whence ſhoote forth divers ſuch like flowers as the *Scabiouſes* doe yeeld, with threds in the middle of them in the like manner, but each budde before it is blowen is more yellow then when it is open, and hath ſtood any time, which yet at the perfection are of a pale yellowiſh colour; in which heads when the flowers are paſt, grow long rough darke coloured ſeede, which being ſhed upon the ground, as ſoone as they are ripe, will ſoone ſpring up before Winter, and will abide greene all the Winter time, and ſhoote up and flower for the moſt part the next yeare following, yet the old roote periſheth not after ſeede time, but abideth many yeares.

2. *Scabioſa montana glabrofolio.* Mountaine *Scabious* with ſmooth leaves.

This mountaine *Scabious* is a low plant, in compariſon of the former, for it ſeldome riſeth above a foote high, bearing many ſhining greene leaves, not any thing hoary at all, but ſmooth ſoft and full of juice, yet divided or cut in on the edges, like the ordinary field *Scabious*, and each of the diviſions dented alittle about the edges: upon the ſtalkes grow the like leaves, two alwayes at a joint, but much more divided than the loweſt, and flowers at the toppes as in other ſorts of *Scabious*, of a fine blewiſh purple colour, with blackiſh threds at the foote of every

flower

flower on the inside: the seede is like the other sorts, and the roote is long blackish, and long lasting after seede time.

3. *Scabiosa montana Dentis leonis folio.* *Scabious* with Dandelion leaves.

This *Scabious* differeth little from other sorts of *Scabious*, but in the leaves, which being somewhat hairy and not smooth, broad at the bottome compassing the stalkes, are so divided on the edges, as a Dandelion leafe is, the lower divisions of the leaves, being blunt at the points, and the uppermost sharpe yet all dented about the edges: the stalkes being hairy and about two foote high, are divided toward the toppes into branches, having two leaves at the joints, so joyned together like the leaves of the Teasell, that they will hold water: the flowers that grow at the toppes are of a pale blewish colour like the rest.

1. *Scabiosa montana maxima.*
The greater mountaine *Scabious.*

4. *Scabiosa prolifera duarum specierum.*
Many flowred *Scabious* of two sorts.

This kind of *Scabious*, that beareth many heads of small flowers, compassing the greater, as is seene in Daisyes, Marigolds, and some other herbes; is of two sorts, one that hath his leaves cut or divided into some broader and larger divisions than the other: the branches towards the toppes where the flowers doe stand are bare, or naked without leaves, save under the very heads, where there stand three or foure small leaves, very finely cut almost as small as Fennell: round about the middle heads of flowers grow forth, other severall small heads of flowers, all alike both for colour and fashion, which are like the ordinary *Scabious*: these give seede like other sorts, and perish after seede time, and either rise again of their own sowing, or being gathered must be new sowen.

5. *Scabiosa argentea angustifolia.*
Silver leafed *Scabious.*

This *Scabious* from a hard wooddy living roote, sendeth forth three or foure stalkes, with divers very long and narrow leaves, almost like grasse, but of a fine white silver like colour, set without order thereon; the toppes of the stalkes are not branched at all, but bare and naked for a good space, bearing one flower at the head of them, white and woolly underneath, but of a pale blew colour above, as other *Scabiouses* are, and consisting in the like manner of many flowers together.

The Place.

The first groweth in many places on the *Alpes*, and in the fields neare unto divers other mountaines and hills in *Austria* and elsewhere: the second groweth on the like places, as on *Snealben* and *Sneberg* hills in *Austria*, &c. as *Clusius* reporteth: the third upon Mount *Calcar* not farre from *Mompelier*: the fourth with the broader leaves, is onely to be found in gardens, but that with finer leaves if it be not the same with the former hath beene observed to grow wilde, about the baths of our Lady neare *Padoa*: the last was found upon the hill *Sumano* neare *Vicenza* in *Italy*.

The Time.

They doe all flower at the time when the other sorts doe.

The Names.

The first is called by *Lobel Scabiosa montana maxima*; by *Camerarius Scabiosa Alpina Centauroides*; by *Lugdunensis Centaurium nothum Dalechampij*; *Bauhinus* calleth it *Scabiosa Alpina foliis Centaurij majoris*: *Bauhinus* maketh the second to be the fift *Scabious* with *Clusius* in his history of plants, as I said before; & calleth it *Scabiosa montana glabra foliis Scabiosæ vulgaris*: the third is onely remembred by *Bauhinus* in his *Pinax* and *Prodromus*, under the title expressed: the fourth is called both by *Lobel* and *Clusius Prolifera*, and their kinde is that with the larger leaves; the other sort *Bauhinus* saith, hath finer cut leaves like unto *Gingidium* or *Visnaga*: the last is remembred as well by *Camerarius in horto medico*, by the name of *Scabiosa graminea folio argenteo flore purpureo*, as by *Bauhinus* under the title expressed.

Scabiosæ globoso flore. Globe flowred *Scabious.*

1. *Scabiosa Neapolitana folio Sinapi sylvestris.* The Globe *Scabious* of *Naples.*

THis *Scabious* hath a straked stalke a foote and a halfe high, divided from the bottome into long branches, having two long smooth leaves divided to the middle ribbe on both sides, and each part divided also, somewhat like unto the leaves of wild Mustard, standing at each joint, and together with them many small haires growing there likewise: the flowers that stand singly at the toppes of every stalke, are of a middle size, and very round at the head, whereof it tooke the name: for the heads of the former sorts are somewhat flat at the toppes, and not so round or globe fashion as these in this ranke, and are of a reddish colour, yet not so deepe or darke red, as that which I set forth in my former Booke, by the name *Scabiosa rubra Indica*, Red flowred *Indian Scabious*: which pertaineth to this order, but that it is described there, and the figure here; the seedes are small, like thereunto, and the rootes likewise perishing after seede time for the most part.

2. *Scabiosa*

2. *Scabiosa flore albo gemino.* Double flowred white *Scabious.*

I gave you in my former Booke, one sort of white flowred *Scabious*, which pertaineth to this order, and is often found in the medowes and marshes neare the sea side in our owne Land, and is not this I meane here to describe unto you, but another differing both from it, and the other here before also with white flowers having such like leaves but larger and broader then it; the stalkes likewise grow higher and stronger, not leaning downewards, and the flowers are larger than it; sometimes but one at the toppes of the branches, but most usually two standing together, and sometimes three, of a faire pure white colour, and after they are past, the heads with seede appeare more round and not flat, but rather a little cone fashion, that is, rising a little higher in the middle: the rootes hereof abide many yeares.

3. *Scabiosa globularia foliis serratis.* The Globe *Scabious* with cut leaves.

This Globe *Scabious* is of a middle sised stature, about a foote and halfe high, and hath all the leaves that grow, both on the lower parts of the stalkes, and at the foote of them, somewhat long narrow and pointed at the ends, deepely dented at the lower ends of them, but not much gashed in on the edges like the other sorts of *Scabious*: but those that grow higheſt neare unto the flowers, are much more and finer cut in: the flowers that stand at the toppes of the slender stalkes, being divided into one or two parts, are very round and close set together, of the like pale blew colour as in other sorts, or a little more purplish like unto the flowers of Devills Bit; but about *Lovaine* as *Lobel* saith, it is found with white flowers: the seede is small, but long and somewhat rough like the other sorts: the roote is small and long, not abiding after it hath given seede.

4. *Scabiosa Globularia Bellidis folijs.* Globe *Scabious* with small Daisye leaves.

This other Globe *Scabious*, (which I am somewhat doutfull, whether to call a Daisye as *Bauhinus* doth, or a *Scabious* as *Clusius* doth) creepeth upon the ground, with trailing branches taking roote as they spread, set with many fat thicke leaves, smooth and greene, not dented at all on the edges, nor small or sharpe at the end, but blunt or round pointed, somewhat like unto the leaves of the small garden Daisye, or *Globularia*, called blew Daisyes, every one like unto them, being small and narrow at the lower end, and broadest toward the end: from the ends of which trailing branche arise slender naked stalkes, about halfe a foote high, bearing on each of them a round ball or head greater than any of the *Globularia's*, yet lesser than those of the field *Scabious*, full of small flowers, of a more deepe purple colour than the *Scabiouses*: after which come small seede lesser than any of the former.

5. *Scabiosa tenuifolia capitulo globoso.* Globe flowred *Scabious* with thinne cut leaves.

This finely cut *Scabious*, hath the lower leaves more finely cut in on the edges, than any of the former, but those on the stalkes which are many, two alwayes set at a joint, are much more finely cut into smaller parts than they up to the toppes, where the flowers stand in round heads, but of the same purplish blew pale colour that is in the ordinary sorts of *Scabious*.

Scabiosa rubra Indica.
The red *Indian Scabious.*

4. *Scabiosa Globularia Bellidis folijs.*
Globe *Scabious* with small Daisye leaves.

5. Scabiosa

5. *Scabiosa tenuifolia globosa.*
Globe flowred *Scabious* with thinne cut leaves.

6. *Scabiosa tenuifolia globosa elatior.*
Another small leafed Globe *Scabious.*

6. *Scabiosa tenuifolia altera elatior.* Another small leafed Globe *Scabious.*

This other riseth up more upright with the single slender stalke, having at the lower joints, two or three small narrow leaves set thereat, finely dented about the edges: but those at the highest part of the stalke stand by couples; the flowers are small and round but like in colour to the other sorts.

The Place and Time.

The first *Bauhinus* saith, *Ferrantes Imperatus* of *Naples* sent him, but nameth not the naturall place; the second is not well knowne where it groweth wilde, but is nourished up in the gardens of those that are Herbarists and lovers of plants: the third groweth in *Germany*, in *Harcynia sylva*, as *Thalius* saith: the fourth, as *Clusius* saith, in rockie and stony places, on the hills of *Hungary* and *Austria*, as also in other untilled places thereabouts: the fift on divers hills in *Germany*; the last we know not the naturall place, the seede comming among other sorts from *Italy*, and flower all of them at the time with the rest.

The Names.

Bauhinus onely remembreth the first by the name of *Scabiosa folio Sinapi sylvestris*; and *Clusius* the second by the same name in the title: the third is called by *Lobel Scabiosa media serrato angustifolio flore Globulariæ*; and by *Thalius in Harcynia sylva Scabiosa Bellidis majoris folio minor*; and by *Bauhinus Scabiosa capitulo globoso minor*: the fourth is called by *Clusius*, *Scabiosa montana minor repens, sive decima*; and by *Camerarius Scabiosa montana repens*; by *Tabermontanus Scabiosa odorata*: but *Bauhinus* following none of them, calleth it *Bellis cærulea montana frutescens*, (as though it did *frutescere* which is nothing so) because the leaves are somewhat like the small Daysie, as I said, and that the *Globularia Monspelienſium* is reckoned as a Daysie, and called *Bellis cærulea*, which is somewhat like unto it; but *Clusius* doth even account that *Globularia*, to be *Scabiosæ pumilum genus*. The fifth is called by *Thalius* in the place before remembred, *Altera Scabiosæ tenuifoliæ species*. The last being a sort not set forth before hath his title fit for it.

Scabiosæ stellato flore. Scabious with Starre like flowers.

1. *Scabiosa Hispanica major.* The greater *Spanish Scabious.*

THis greater *Spanish Scabious* hath large soft woolly leaves, much cut in on both edges, like the leaves of the great field or Corne *Scabious*, each part also dented about the edges, the stalkes rise to the heighth of two foote, bearing such like leaves at the joynts, but smaller up to the toppes, where they branch forth into severall small sprigges, bearing every one a head of many flowers, like the other *Scabiouses*, but each made of harder and stiffer skinnes, of a whitish colour, in whose places after they are past, the cuppes of huskes wherein they stood, doe appeare like blacke starres, with divers points, wherein the seede is contained, which is somewhat long, thicke, and hairy, like the other sorts: the roote is thicke and white like the common kinde, but perisheth every yeare, after it hath borne flower or seede.

2. *Scabiosa*

2. *Scabiosa Hispanica minor.* The lesser *Spanish Scabious.*

The lesser *Spanish Scabious* is altogether like the former greater, but that it is lesser in every part; and that the leaves are a little smaller, or finelier cut in, and the flowers not white as the former, but of a blewish purple colour.

1. *Scab osa Hispanica major.*
The greater *Spanish Scabious.*

3. *Scabiosa arborea Cretica Ponæ.*
Pona his Shrubbe *Scabious* of *Candy.*

This *Candy Scabious* riseth up with a wooddy stalke, from whence spring divers hard and wooddy branches, white or hoary all over, as the leaves are also, which are thicke set thereon, without any division or denting at the edges, being whole like unto the great *Cyanus* or blew Bottle: at the ends of the branches come forth small naked stalkes, bearing a head of flowers, very like unto the former great *Spanish Scabious*, but of a pale reddish colour; the seede conteined in those starre like huskes, are smaller, and smell a little sweeter then other sorts of *Scabious* doe; the roote is long and hard, divided into divers parts, abiding the Winter both in the naturall and other warme Countries, and holding his greene leaves also, but is more tender, not able to endure the sharpenesse of our frosts and colds. *Camerarius* maketh mention of a *Scabiosa* which he calleth *Gallica* like hereunto, but that he saith it hath small long blackish leaves, whereas this hath white and woolly, else it might be judged the same.

Gallica Camerarij

4. *Scabiosa stellata minima.*
Small Starre like *Scabious.*

This small *Scabious* is very like the smaller *Spanish Scabious*, having divers narrow leaves, about two inches long, much cut in and divided on the edges, the stalke is scarce halfe a foot long, with such like leaves thereon, and small pale blewish flowers as in the *Spanish* kinde; the huskes likewise have divers points, standing open spread like a starre, from the middle whereof come forth five small long reddish threds, like haires standing out of the huske: the seede is small, but like the other; the roote is small and perisheth every yeare.

The Place.

The two first sorts *Clusius* saith he found in the borders of the Vineyards, and in the paths of the fields about *Salamanca* in *Spaine*, and in other places; the smaller of which *Bauhinus* saith he found upon the shore neere *Venice*. The third in *Candy* as *Pona* saith, who had it from *Signior Contarini* of *Venice*. The last *Bauhinus* saith, groweth in *Provence* of *France*.

The Time.

The two first *Spanish* kindes as also that of *Candy*, flower somewhat later then the former sorts, so that they seldome give good seede with us, and therefore we are still to seeke new seede to sow.

The Names.

The two first *Clusius* calleth *Hispanica*, and so doe all others that mention them, onely *Dodonæus* calleth them *peregrina*; and *Bauhinus* calleth the first *stellata laciniato folio major*, and the other *minor sive maritima*. The third *Pona* in his *Italian Baldus*, calleth by the same name is in the title, *Lobel*, *Lugdunensis*, and *Gerard* also *Scabiosa peregrina*; *Tabermontanus Scabiosa peregrina foliis non dissectis*, and *Bauhinus Scabiosa stellata folio non dissecto*, *Cæsalpinus Scabiosa arboreſcens*. The last *Bauhinus* onely setteth forth under the title expressed, both in his *Pinax* and *Prodromus*, and saith he accounteth it to differ from the lesser *Spanish* kinde, in some notable parts.

The Vertues.

Now that I have described unto you all the sorts of *Scabious*, whose variation and differencē consisteth chiefly in the leaves and flowers, being yet in taste, not so much differing the one from the other, and therefore their faculties are to be accounted alike, so that the vertues in any one are not so peculiar, but that they may be referred to the generall, which are these; It being hot and dry, is of an opening, clensing, digesting, and attenuating quality, whereby it is very effectuall for all sorts of coughs, shortnesse of breath, and all other the diseases of the brest and lunges, ripening and digesting cold flegme, and other tough humours, voyding them forth by coughing and spitting. It ripeneth also all sorts of inward ulcers and apostumes, yea the plurefie also, if the decoction of the dry or greene herbe, being made with wine be drunke some time together, thereby voyding it forth by the urine, as well as other waies; or if you would have it more effectuall, take this receipt, *viz.* an handfull of dryed *Scabious*, an ounce of Licoris scraped and cut into thinne slices, a dozen figges washed and cut into peeces, an ounce of Anisseede, and as much of Fennelseede bruised, and halfe an ounce of white *Orris* rootes cut into thinne slices: let all these be steeped for a night, in a quart of faire water, (or rather in so much wine) boyling them the next day, untill a third part be consumed at the least, whereof take a draught every morning and evening, somewhat warme, well sweetned with Sugar or Hony, which worketh wonderfully to helpe all the diseases aforesaid. Foure ounces of the clarified juice of *Scabious* taken in the morning fasting, with a dram of *Mithridatum* or *Venice* Treakle, doth free the heart from any infection of the plague, or pestilence, so as upon the taking thereof they sweate two houres in their beds at the least, yet after the first time taking, let them that are infected take the same proportion againe, and againe if need be, for feare of further danger, the greene herbe

herbe alſo bruiſed, and applyed to any Carbuncle or Plague ſore, is found certaine by good experience, to diſſolve or breake it within the ſpace of three houres: the ſame inward and outward application, is very availeable againſt the biting or ſtinging of any venemous beaſt: the ſame decoction alſo drunke, helpeth the paines and ſtitches in the ſides; the decoction of the rootes taken for forty dayes together, or the powder of them, to the quantity of a dramme at a time, taken in whey, doth as *Matthiolus* ſaith, wonderfully helpe thoſe that are troubled with dangerous running or ſpreading ſcabbes, tetters, or ringwormes, yea although they proceed of the *French* pox, as himſelfe ſaith, he hath found true by certaine experience: the juice or the decoction drunke, doth wonderfully helpe thoſe that are broken out into ſcabbes, and itches: and the juice alſo made up into an oyntment and uſed, is effectuall for the ſame purpoſe. The ſame alſo wonderfully helpeth all inward wounds, be they made by thruſt or ſtroke, by the drying, clenſing, and healing quality therein. A Syruppe made of the juice and Sugar, is very effectuall to all the purpoſes aforeſaid, and ſo is the diſtilled water of the herbe and flowers made in due time, eſpecially to be uſed when the greene herbe is not in force to be taken; the decoction of the herbe and rootes outwardly applyed, doth wonderfully helpe all ſorts of hard or cold tumours, or ſwellings in any part of the body; and is alſo as effectuall for any ſhrunke ſinew or veine in any place: the juice of *Scabious* made up with the powder of *Borax* and *Camphire*, doth notably clenſe the skinne of the face or any other part of the body, as freckles, pimples, and other ſmall eruptions therein, yet it prevaileth alſo in greater deformities, as the Morphew, and Lepry; the ſame decoction doth alſo helpe the redneſſe, and ſpots in the white of the eyes, uſed either of it ſelfe, or with the juice of Fennell; the head waſhed with the ſame decoction clenſeth it from dandraffe, ſcurfe, ſcabbes, ſores, itches, and the like, being uſed warme; tents alſo dipped in the juice or water thereof, doth not onely heale all greene wounds, but old ſores and ulcers alſo, both by ſtaying their fretting or running qualities, and clenſing and healing them up afterwards; the herbe alſo bruiſed and applyed to any place, wherein any ſplinter, broken bone, arrow head or other ſuch like thing lyeth in the fleſh, doth in ſhort time looſen it, and cauſeth it to be eaſily drawne forth.

CHAP. X.

Morſus Diaboli. Divels bit.

THere reſteth yet this kinde of *Scabious* to be entreated of, being of all Herbariſts accounted an eſpeciall different kinde thereof, yet ſome referre it to the *Iacea's*, but not properly; the former ages knew but one ſort, we have in theſe times found out ſome others, as they ſhall preſently be ſhewed you.

1. *Morſus Diaboli vulgaris flore purpureo.* Common Devills bit.

Devils bit riſeth up with a round greene ſmooth, and not hairy ſtalke, two foote high or thereabouts, ſet with divers long, and ſomewhat narrow, ſmooth, darke greene leaves, ſomewhat ſnipt about the edges for the moſt part, being elſe all whole, and not divided at all, or but very ſeldome, even to the toppes of the branches, which yet are ſmaller then thoſe below, with one ribbe onely in the middle, and being broken yeeld not ſuch threds as the *Scabious* doth; at the end of each branch ſtandeth a round head of many flowers, ſet together in the ſame manner, or more neatly or ſuccinctly then the *Scabious*, and of a more blewiſh purple (but not darke red as *Gerard* ſaith, for ſuch I never ſaw any) colour, which being paſt, there followeth ſeede like unto the *Scabious* that falleth away in the ſame manner: the roote is ſomewhat thicke; but ſhort and blackiſh with many ſtrings, faſtned thereto, abiding after ſeede time many yeares: Fabulous antiquity (the Monkes and Fryers as I ſuppoſe, being the firſt inventors of the Fable) ſaid, that the Devill envying the good that this herbe might do to mankinde, bit away part of the roote, and thereof came the name *Succiſa*, Devils bit which is ſo groſſe and ſenſleſſe a relation, that I merveile at the former times ſtupidity, to receive as true ſuch a fiction. Of this kinde ſome doe make a greater and a leſſer, which I thinke rather commeth from the place of growing, then from the nature of the plant. Vnto this plant in my opinion belongeth the *Scabioſa rubra Auſtriaca* of *Cluſius*, ſet forth in my former booke; for the leaves thereof being all whole, and the flowers red, doe notably reſemble this Devils bit, and may be a ſpecies thereof, proper to *Germany*, *Auſtria*, *&c.* *Bauhinus* maketh mention of one of this kind, that hath hairy leaves not differing in any thing elſe, and for his author nameth *Geſner in hortis Germaniæ*, who as hee ſaith called it *Morſus Diaboli hirſuta rarior*, which I cannot finde in *Geſner*, but of the three ſorts of *Scabious*, one of the leſſer he calleth *Scabra hirſutaque*, having leaves without diviſions, which whether he ſhould meane this I know not: for he nameth it not *Morſus Diaboli*, therefore I leave it to time to declare the truth thereof.

2. *Morſus Diaboli flore albo.* Devils bit with a white flower.

This ſort differeth not from the former in any other thing, then in the flower, which is of a pure white colour as ſome other ſorts of the *Scabiouſes* are, and that the greene leafe is not altogether of ſo darke a colour.

3. *Morſus Diaboli flore carneo.* Devils bit with bluſh coloured flowers.

This other ſort likewiſe differeth neither in roote ſtalke or leafe, from the former, onely the flowers which are of an incarnate or bluſh colour, maketh the difference from both the other.

4. *Morſus Diaboli alter flore cæruleo.* Strange Devils bit.

This herbe which I place here for ſome likeneſſe, hath divers leaves riſing from the roote, every one ſeverally on a long footeſtalke ſomewhat like unto Betony or Sage, dented about the edges, the ſtalke riſeth up amongſt them a foote or more high, bearing one large flower at the toppe, hanging downe the head and made all of blewiſh threds.

The Place.

The firſt groweth as well in dry meddowes and fields as moiſt, in many places of this land, but the other two ſorts are more rare and hard to meete with, yet they are both found growing wild about *Apple dore*, neere *Rye* in *Kent*. The laſt groweth in the fields that are on the mountaines beyond the Seas.

The Time.

They flower ſomewhat later then the *Scabiouſes*, as not uſually untill *Auguſt*.

1. *Morsus Diaboli vulgaris.*
Common Devils bit.

Scabiosa rubra Austriaca.
The red *Hungarian Scabious.*

The Names.

It is usually called *Morsus Diaboli*, by most writers, or *Succisa* as *Fuschius* doth, and others after him, a *præmorsa* or *succisa radice*. Some there have beene that have thought it to be the *Geum* of the ancients; others take it to be *Nigina* of *Pliny*, whereof he maketh mention in his 27. booke, and 12. Chapter, in these words. The herbe that is called *Nigina*, hath three long leaves like the *Endives*. *Fabius Columna* referreth it to *Picnocomon* of *Dioscorides*. The *Italians*, *Spaniards*, and *French*, and so likewise all other nations follow the Latine name, each nation in their severall dialect: or else the *Germanes* first calling it *Abbiss* and *Tewfells abbiss*, caused the Latine name, and all other tongues following it, to call it thereafter: And we following the *Germanes* Devils bit. The last is the second *Aphyllantes* of *Dalechampius*.

The Vertues.

The taste hereof being somewhat more bitter, declareth it to be hot and dry in the second degree compleate, and therefore is more powerfull and availeable, for all the purposes whereunto *Scabious* is appropriate, either inwardly or outwardly, as they are declared before, and especially against the plague, and all pestilentiall diseases, or feavers, poisons also, and the bitings of venemous beasts, the herbe or roote being boyled in wine and drunke: the same also helpeth those that are inwardly bruised by any fall, or crushed by any casualty, or bruises by outward beatings or otherwise, dissolving the clotted or congealed blood, and voyding it by excretion, or otherwise, and the herbe or roote beaten and applyed outwardly, taketh away the blacke and blew markes, that remaine in the skinne after some accidents: the decoction of the herbe, wherein some Hony of Roses is put, is very effectuall to helpe the inveterate tumours and swellings of the Almonds and throate, which doe hardly come to ripenesse, for it digesteth, clenseth, and consumeth the flegme sticking thereto, and taketh away the tumours by often gargling the mouth therewith: it helpeth also to procure womens courses, and to ease all paines of the matrix or mother, to breake and discusse windes therein and in the bowels: the powder of the roote taken in drinke, driveth forth the wormes in the body, the juice or distilled water of the herbe, is as effectuall for greene wounds or old sores, as the *Scabiouses* be, and clenseth the body inwardly; and the head outwardly, from scurffe and sores, itches, pimples, freckles, morphew, or other deformities thereof, but especially if a little *Vitriol* be dissolved therein.

CHAP. XI.

Plantago. Plantaine.

VNder the name of Plantaine, is not onely comprehended all the sorts of Plantaine properly so called, whereof there are a great many sorts, as I shall shew you in this Chapter, but divers other sorts of herbes much differing from them, which shall be set forth in the next Chapter following, each kinde by it selfe as neare as I can, and becaus the Plantaines are divided into greater and lesser, or broader

and

and narrower leafed ones, I thinke it the beſt method to ſeparate them, and ſpeake of each of them and their *ſpecies* apart, and not confound them together to avoide miſtaking. One of theſe Plantaines are called Roſe Plantaine, which although I have ſet it forth in my former Booke, yet I thinke it fit here to expreſſe it againe, and the ſeverall formes and varieties therein.

Plantagines latifoliæ. Broad leafed Plantaines.

1. *Plantago latifolia vulgaris.* Common Waybredde or Plantaine.

THis common Plantaine I here ſet in the front of all the reſt, becauſe I would ranke it with the reſt of the kinde, which is well knowne to all to beare many faire broad almoſt round pointed leaves, with ſeaven ribbes or veines in every of them for the moſt part, running all the length of the leafe, of a ſad greene colour on the upper ſide, and more yellowiſh greene underneath; among which riſe up divers ſmall ſlender ſtemmes or ſtalkes, a foote high more or leſſe, not eaſie to breake, naked or bare of leaves unto the toppes, where each ſtalke beareth a ſmall long round blackiſh greene ſpike or ſcaly head, whoſe bloomings or flowers, are ſmall whitiſh threds with aglets hanging at the ends of them, almoſt like unto the blooming of Corne, after which come browne ſmall ſeede, encloſed in the ſeverall ſmall ſcales or skins: the roote is made of many white ſtrings, growing ſomewhat deepe, and taking ſo faſt hold in the ground, that it is not eaſie to pull it up.

2. *Plantago latifolia maxima.* The greateſt Plantane.

This great Plantane is in all things like the former, but that it exceedeth it in greatneſſe and height, for the leaves that lie on the ground are ſixe inches, that is, halfe a foote long many times and more, and foure inches broad, and the ſtalkes ſuſtaining every leafe, neare an handbreadth long: the naked ſtalkes that beare ſpiked heads like the other, are two cubits high, and the head or ſpike a foote long, the roote hereof is blackiſh and ſtringy: Sometimes this kinde is found to have leaves a foote long and halfe a foote broad, ſomewhat torne on the edges, and having ſome leaves under the ſpiked heads. *Laciniatis folijs.*

3. *Plantago major incana.* Great hoary Plantaine.

The hoary Plantaine is likewiſe like the firſt, but that the leaves are very hoary white, eſpecially in the hotter Countries of *Spaine, &c.* much more then in theſe colder climates, and ſomewhat ſmall, it ſeldome beareth any ſpiked heads in *Spaine* as *Cluſius* ſaith, but when it doth, they are ſmaller then the firſt, and the rootes are blackiſh and ſtingy. *Iohannes Thalius* in *Harcynia ſylva* mentioneth a ſmaller kinde hereof, both in leaves and flowers. *Minor.*

4. *Plantago exotica ſinuoſa.* The ſtrange crumpled Plantaine.

This ſtrange Plantaine upon the firſt yeares ſowing of the ſeede, which was ſent from beyond ſea, riſe up but

1. *Plantago latifolia vulgaris.* Common Waybredde or Plantaine.

2. 3. *Plantago maxima & flos incana* The greateſt Plantaine and the flower of the great hoary Plantaine.

4. *Plantago exotica sinuosa.*
The strange crumpled Plantaine.

Plantaginis exoticæ sinuosæ spica.
The spiked head of the strange Plantaine.

5. *Plantago latifolia rosea multiformis, foliumque incisum & Spiralis.*
Broad leafed Rose Plantaine of much variety, with a jagged leafe, and bushing spiked head.

with onē great and largē leafe, almost a foote long, foulded as it were together, and wound about spire fashion into two parts at the further end thereof, which opening it selfe, yet remaining somewhat hollow, was much crumpled and waved on the edges; the further end shewing somewhat like unto a Plantaine leafe: but the bottome of the leafe had on each side thereof a large peece as it were torne from it, but yet growing to it, which were likewise crumpled and waved, and each of them shewing the forme of a Plantaine leafe, whose taste also was not unlike, so that the whole leafe seemed, as if divers great large leaves were joyned together to make one: this leafe perishing the first yeare, there rose up the next Spring divers leaves close together, not formed into one as the former, but as if divers leaves were joyned together, each bearing the Plantaine forme, but somewhat rounder a little crumpled and waved as thē former was; the stalke rose up in the middle of these leaves, above a foote and a halfe high, bearing thicke and short spiked flattish heads and seeds therein, like unto the others; the roote is composed of a thicke round head, at the toppe with many long strings or fibres issuing thence downewards; thereby taking strong hold in the ground.

5. *Plantago latifolia rosea multiformis.* The broad leafed Plantainē of much variety.

This kind of Rose Plantaine is of many sorts, yet all of them have large and sometimes hoary greene leaves spread

ſpread on the ground either whole like the former great Plantane, or a little jagged toward the lower part: among which riſe up ſhort naked ſtalkes, bearing every one at the top, either a broad round head made of many ſmall ſhort greene leaves in the faſhion of a Roſe, or a ſpiked thicke long head made of many ſhorter greene leaves buſhing thicke below and ſmaller upwards, and ſometimes one plant will have both theſe formes at once together, and ſome again out of the middle of the Roſe will have another ſhort ſpike of green leaves riſing up; and others at the bottome of the Roſe or ſpike, will have one or two other ſmall tufts either round or long. One ſort there is likewiſe whoſe long ſpiked heads, is parted into many and ſundry ſeverall ſparſed ſpikes, and therefore called *Spiralis*: other varieties alſo are ſometimes ſeene in ſome of this kinde, as nature liſteth to produce them: the roote is like unto the former.

The Place.

The firſt groweth every where, in fields and in the pathwayes generally: the ſecond about *Mompelier* in *France*: the third in divers places of *Spaine*, where *Cluſius* obſerved it, and in ſome other colder countries alſo: the fourth came from *Caſpar Pilleterius* of *Mompelier* to Dr. *Lobel*, and the ſeede ſowen with Mr. *Iohn Neſmit* a *Scottiſhman*, chiefe Chyrurgion in his time to King *Iames*, where it grew divers yeares: the laſt, although a ſtrange Plantane, yet naturally found in our owne country, and riſing as it is likely from the third ſort, and from thence cheriſhed in gardens.

The Time.

They are all in their beauty about *Iune*, and the ſeede ripeneth ſhortly after.

The Names.

It is called in Greeke ἀρνόγλωσσον and ἀρνόγλωσσος, *Arnogloſſum* and *Arnogloſſos a forma ſc. agnina lingua*: others call it πολύνευρ& *multinervia*, and ἑπτάνευρ& *ſeptinervia*, either of the many, or of the ſeven ribbes or veines that are in every leafe? in Latine *Plantago a planta vocabulo*: the *Arabians* call it *Liſen* and *Loſan alhamel*: the *Italians Plantagine*: the *Spaniards Llhanten* and *Tamchage*: the *French Plantain*: the *Germanes Wegerich*: the *Duth Wechbre*: the *Engliſh* Waybredde, not Waybread, as divers corruptly call it, and Plantane: the firſt is called generally of all Authors *Plantago major*, or *latifolia*, or *vulgaris*. *Brunfelſius* and *Tragus* call it *Plantago rubra* becauſe the ſeede thereof is redder than of others: the ſecond *Bauhinus* calleth *Plantago maxima tota glabra*: the third *Cluſius* calleth *Plantago major incana*, and *Plantago Salmaticenſis*, judging it to be *Cynogloſſum* of *Dioſcorides*, which he ſaith beareth neither ſtalke nor flower, as *Cluſius* ſaith this doth very ſeldome in *Spaine*, but I doe not hold that a ſufficient reaſon, to judge it to be *Cynogloſſum*. *Fuſchius*, *Dodonæus*, *Geſner*, and others, call it *Plantago media*, and *Lobel Plantago major incana*, yet *Turner* and *Tabermontanus* call it *Plantago minor*; the fourth *Lobel* onely expreſſed the firſt leaves in his *Appendix* to the *Adverſaria*, by the title of *Plantago umbilicata latifola*, and *convoluta unifolia*; I have added the Spikes, and call it *Plantago exotica ſinuoſa*, as beſt agreeing thereto in my opinion: the laſt *Cluſius* had the figure thereof from *Iames Garret* an Apothecarie, ſometimes in *Lyme-ſtreete London*, which he cauſed to be taken from the living plant, growing in his garden neare *London Wall* by *Aldgate*, and thereupon called it *Plantago peregrina latifolia Garreti*, and *Plantago latifolia exotica*. *Bauhinus* calleth it *Plantago latifolia incana ſpicis variis*; and that other with many ſpikes *Lobel* calleth *Plantago pannicula ſparſa*, and may alſo be called *Plantago ſpiralis*.

Plantagines anguſtifoliæ. Narrow leafed Plantaines.

1. *Plantago Quinquenervia major.* The greater Ribbeworte Plantane.

THis greater Ribbewort Plantane bath divers narrow, long and hairy darke greene leaves lying on the ground, with five veines or ribbes for the moſt part in every one of them, and pointed at the ends; among which riſe up many naked and ſtriped ſtalkes, ſomewhat hairy, at the toppes whereof grow ſuch like long and ſpiked darke greene heads, as in the firſt common Plantaine, and flowring in the ſame manner, but greater and ſhorter, wherein lie ſuch ſeede as in the former but greater and of a darker colour; the rootes are long, fibrous or ſtringie like the former. This ſometimes is found varying in the heads, for ſome will have two heads upon a ſtalke, or one head parted into two parts, or with two or more ſpiked heads, growing at the bottome of the head.

2. *Plantago anguſtifolia Roſea & multiformis.* Variable Roſe Ribbewort.

This Roſe Plantane hath ſuch like leaves as the former hath, that it is not, or very hard to be knowne from it, before the ſtalkes with heads beginne to appeare, which when they are full ripe, ſhew themſelves in a variable manner; ſome having large or long narrow leaves ſet together, ſomewhat ſparſedly, imitating a looſe or diſperſed Roſe; others having ſhorter greene leaves, and more compact and cloſed, making a more comely forme of a Roſe, ſometimes fully laid open, and ſometimes more cloſe, and as it were halfe cloſed, and ſometimes out of the middle of the Roſe will ariſe, two or three or more ſhort ſtalkes, bearing each a ſmall greene Roſe, and therefore called *Prolifera*, made of many ſmall leaves ſet together in the ſame manner, and ſometimes many ſhort ſpikes ſet cloſe together in one head, or ſeparate each by it ſelfe: this kinde beareth no ſeede that ever was obſerved, but is encreaſed by ſlipping or parting the roote, and ſetting it againe. *Prolifera.*

3. *Plantago anguſtifolia minor.* The leſſer Ribwort Plantane.

The ſmaller Ribbewort Plantane, is in every part thereof like the firſt ſort, but that it groweth ſmaller and lower, and this onely maketh it to differ from it.

4. *Plantago anguſtifolia ſerrata.* *Spaniſh* Ribbewort with dented leaves.

This *Spaniſh* Ribbewort is like the leſſer ſort, but ſmaller, narrower and harder in handling, being dented about the edges, and ſo ſharpe with all, that they might ſeeme to be prickles, which hath cauſed ſome to call it *peregrina ſpinoſa*: the ſpiked heads ſtand upon ſlender ſtalkes, about halfe a foote high, being ſomewhat open or diſperſed.

5. *Plantago anguſtifolia fruticans.* Shrubbe Plantane.

The ſhrubbe Plantaine is in all things like the ſmaller Ribbeworte, but that the leaves are whiter, and the ſtalkes high and wooddy, with ſmall leaves on them, and the heads are in faſhion like them, but ſhorter and ſofter, bearing whitiſh bloomings and darke ſeede.

1. 4. *Plantago angustifolia sive quinque nervia major & serrata.*
The greater Ribbewort Plantane with plaine and dented leaves.

2. *Plantago angustifolia rosea & multiformis.*
Variable and Rose RibbeWort.

3. *Plantago angustifolia minor.*
The lesser Ribbewort Plantane.

6. *Plantago Apula bulbosa.*
Bulbed Ribbewort of *Naples.*

8. *Trinervia folio angustissimo.*
The smallest Ribbewort.

6. *Plantago Apula bulbosa.* Bulbed Ribbewort of *Naples.*

This Bulbed Ribbewort hath a long ſmall and round head, for the upper part of his roote, like unto a ſmall Bulbe or Onion, of the bigneſſe of an Haſſell Nut or bigger, from whence ſhoote downe into the ground, many thicke and blacke long fibres: from this head or bulbe ſpring forth, many long and narrow leaves like the firſt Ribwort, lying upon the ground, but that each of them are more hairy and dented or cut on the edges into gaſhes, ſeparate a good diſtance one from the other, ſomewhat like unto Bucks horne Plantane, from among which riſe riſe up ſlender hairy round ſtalkes, about a foote high, bearing ſuch like ſpiked heads, as the firſt doth, with pale yellow bloomings, and ſmall blackiſh ſeede after them.

7. *Plantago montana trinervia.* Small mountaine Ribbewort Plantane.

This ſmall mountaine Ribbewort, hath divers very ſmall and long hoary white leaves, having each of them, but three ribbes or veines a peece running through them, whereof it tooke the name: the ſtalkes that riſe among them are ſmall, and Ruſh like, not much above a foot high, whereon ſtand ſmall thicke and ſhort heads, with ſmall flowers on them, made of foure ſmall ſtiffe leaves, and ſmall white threds hanging out of them, like the other ſorts of Plantane, after which come ſuch ſeede as is in the reſt: the roote hath a ſmall long necke, hairy above, and ſet with pale long fibres underneath.

8. *Plantago trinervia folio anguſtiſſimo.* The ſmalleſt Ribbewort.

This leaſt Ribbewort hath ſuch like leaves as the laſt lying upon the ground, but they are neither ſo white nor ſo long, very narrow and ſome longer, or ſhorter than others, all of them ſmooth and without any haires upon, or but a very little ſhew; the ſmooth ſtalkes are many that riſe up amongſt them, being of divers ſiſes, for ſome riſe not above foure inches, others halfe a foote, or a foote, and ſome a foote and a halfe high, whereon grow ſmall and ſomewhat long ſpiked heads, the rootes are many ſmall white fibres.

9. *Plantago anguſtifolia paniculis lagopi.* Hares foote Plantaine.

This Plantane hath many long ribbed rough hairy leaves, very like unto the firſt Ribbewort, but ending in a ſmaller and ſharper point, it ſendeth forth a number of ſmall round browniſh ſtalkes of divers ſiſes or heights, ſome being not above two or three inches high, and others halfe a hand breadth, or an hand breadth high at the moſt; whereon ſtand ſmall long reddiſh heads, like unto the heads of *Lagopus* or Hares foote, ſome being longer, and others ſmaller and ſhorter, but all ſoft with ſmall reddiſh flowers at them, and ſmall threds hanging from them, as in the other ſorts, and ſmall ſeede following: the roote is ſomewhat long with many reddiſh fibres growing there from. This ſometimes is found ſo ſmall, that it ſcarſe exceedeth three fingers in height, being more hairy, and having ſmaller and rounder heads.

The Place.

The firſt without dents on the edges, and the third grow with us in divers Meddowes and fieldes, and by pathwayes: in gardens alſo it is found as a weede: the ſecond is found wilde in divers places of this Kingdome, and brought and cheriſhed in gardens for the rarietie: the fourth and fift were brought us from *Spaine* by *Guillaume Boel* often remembred both in this and my former Booke where he found them: the ſixth and ſeventh grow in the Kingdome of *Naples*, *Fabius Columna* having found them there and ſet them forth: the eight *Bauhinus* ſaith, groweth with them about *Baſſill*, by the way ſide and among rubbiſh: the laſt in the fields about *Nemauſium.*

The Time.

Theſe all flower and ſeede at the time, that the former doe, that is, in *May*, *Iune*, and *Iuly.*

The Names.

This is called in Greeke πεντάνευρος *Pentaneuros*, that is, *Quinquenervia*; in Latine *Plantago anguſtifolia*, and *Plantago media & minor* of ſome, and *Lanceolata* and *Lanceola*, in *Italian Lancivola*, in *French Lanceola*, in high *Dutch Spitzer Wegerich*, in low *Dutch Honts ribbe*, in *Engliſh* Ribbewort, and Ribbewort Plantane. The firſt is generally called either *Plantago anguſtifolia major*, or *Plantago Quinquenervia major* of many, of *Fuſchius*, *Dodonæus*, *Geſner* and others *Plantago minor*; of *Matthiolus* and *Lugdunenſis* *Plantago longa*: the ſecond hath many titles to expreſſe it, according to the formes of the ſpikes, as *Plantago toroſa prolifera*, *roſea*, &c. the third is remembred by *Thalius* in *Hercynia ſylva*: the forth and fift *Cluſius* maketh mention of in his *Curæ poſteriores*, but the ſame *Guillaume Boel*, brought the dried plants and ſhewed them to me and others, before hee ſhewed them to him; and I had the ſeedes of them, as of many other things, which hee gathered moſt part upon my charge, whereof many ſprang and ſeeded, and in their places are remembred: others ſprang but ſeeded not, and ſo we have loſt the kindes, which wee have not of many things gotten againe: the ſixt *Fabius Columna* called *Plantago Apula laciniata bulboſa*, and *Bauhinus* *Plantago piloſa bulboſa*; the ſeventh *Columna* alſo calleth *Plantago altera minima trinervia montana incana*, and *Bauhinus* *Plantago trinervia montana*: the eight *Bauhinus* calleth *Plantago trinervia folio anguſtiſſimo*: the laſt he alſo calleth *Plantago anguſtifolia paniculis Lagopi.*

The Vertues.

All theſe ſorts of Plantane both the greater and the leſſer, both the broader and the narrower leafed, are of one propertie, that is, cold and drie in the ſecond degree. I thought good to ſpeake of their vertues in the end of all their deſcriptions, to avoid prolixitie and tautologie in repeating the ſame properties divers times. All the Plantanes, (but ſome hold the Ribbewort to be the ſtronger and more effectuall) have theſe properties hereafter enſuing. The juice of Plantane depurate or clarified, and drunke for divers dayes together, either of it ſelfe, or in other drinke, prevaileth wonderfully againſt all torments and excoriations in the guts or bowells, helpeth the diſtillations of rheume from the head, and ſtayeth all manner of fluxes in man or woman, even the feminine courſes alſo, when they come downe too abundantly: it is good to ſtay the ſpitting of bloud, and all other bleedings at the mouth, by having a veine broken in the ſtomacke, and that maketh bloudy or foule water by any ulcer in the veines or bladder, as alſo to ſtay the too free bleeding of wounds; it is held alſo an eſpeciall remedy, for thoſe that are troubled with the Ptiſicke or Conſumption of the lungs, or have ulcers in their lungs; or have coughs that come of heate: the decoction or powder of the rootes or ſeede, is much more binding, for all the purpoſes afore ſaid than the herbe is. *Dioſcorides* ſaith, that if three rootes be boiled in wine and taken, it helpeth the *tertian* ague, and foure rootes the *quartane*; but I hold the number to be fabulous, yet the decoction of divers of them, may be effectuall; but *Tragus* holdeth that the diſtilled water thereof drunke before the fit is more proper:

the ſeede made into powder, and mixed with the yolke of an egge, and ſome wheate flower made into a cake and baked, either in an oven, or betweene a couple of tyles heated for the purpoſe, this cake prepared every day freſh and eaten warme, for ſome few dayes together, doth mightily ſtay any fluxe of the ſtomacke, when the meate paſſeth away indigeſted, and ſtayeth likewiſe the vomitings of the ſtomacke: the herbe, but eſpecially the ſeede which is of more ſubtile parts, is likewiſe held to be profitable againſt the dropſie, the falling ſickneſſe, yellow jaundiſe, and the oppilations or ſtoppings of the liver or reines: the rootes of Plantane and Pellitory of *Spaine*, beaten to powder and put into hollow teeth, taketh away the paines in them: the clarified juice, or the diſtilled water but eſpecially that of Ribbewort, dropped into the eyes cooleth the inflammations in them, and certainely cureth the pinne and webbe in the eye, and dropped into the eares, eaſeth the paines therein, and helpeth and reſtoreth the hearing: the ſame alſo is very profitably applied, with juice of Houſleeke againſt all inflammations and eruptions in the skinne, and againſt burnings or ſcaldings by fire or water; the juice or the decoction made either of it ſelfe, or with other things conducing thereunto, is a lotion of much uſe and good effect for old or hollow ulcers that are hard to be cured, for cancres and ſores in the mouth, or privie parts of man or woman, and helpeth alſo the paines of the hemorrhoides or piles, and the fundament: the juice mixed with oyle of Roſes and the temples and forehead annointed hterewith, eaſeth the paines of the head proceeding from heate, and helpeth franticke and lunaticke perſons very much, as alſo the bitings of Serpents, or a madde Dogge: the ſame alſo is profitably applied to all hot gouts in the feete or hands, eſpecially in the beginning, to coole the heate, and repreſſe the humours; it is alſo good to be applied where any bone is out of joint, to hinder inflammations, ſwellings, and paines, that preſently riſe thereupon: the powder of the dried leaves taken in drinke, killeth the wormes of the belly, and the ſaid dried leaves boiled in wine, killeth the wormes that breede in old and foule ulcers: One part of Plantane water, and two parts of the brine of powdred beefe boyled together and clarified, is a moſt ſure remedy to heale all ſpreadnig ſcabbes and itch in the head or body, all manner of tetters, ringwormes, the ſhingles, and all other running and fretting ſores: Briefely, all the Plantanes are ſingular good wound herbes, to heale freſh or old wounds and ſores, either inward or outward. *Eraſmus* iu his *Colloquia*; reporteth a prettie ſtory of the Toade, who being ſtung or bitten by a Spider, ſought out Plantane, and by the eating thereof was freed from that danger.

CHAP. XII.

Holoſteum ſive Plantago marina. Sea Plantane.

THere remaine ſome other ſorts of herbes referred to the Plantanes, which ſhall follow in their order, and firſt of thoſe are called *Holoſtea*, which for want of a fitter name we call Sea Plantane.

1. *Plantago marina vulgaris.* Ordinary Sea Plantane.

This ſea Plantane hath many narrow long and thicke greene leaves having here and there a dent or two on the one edge pointed at the end, among which riſe up ſundry bare ſtalkes, with a ſmall ſpiked head thereon ſmaller than Plantane, elſe alike both in blooming and ſeede: the roote is ſomewhat white thicke and long with long fibres thereat abiding many yeares.

1. *Plantago marina vulgaris.* Ordinary Sea Plantane.

2. *Holoſteum Salmanticum.* *Spaniſh* Sea Plantane.

2. Hole-

3. *Holosteum angustifolium majus, sive Serpentaria major.*
The greater Sea Plantane with grassie leaves.

4. *Holosteum angustifolium minus sive Serpentina minor.*
The lesser Sea Plantane with grassie leaves.

5. *Holosteum Creticum sive Leontopodium Creticum.*
Candy Sea Plantane.

Leontopodium idem diverse expressum.
The same plant diversly expressed.

2. *Holosteum Salmanticum.* *Spanish* Sea Plantaine.

This *Spanish* Sea Plantaine also differeth not much from the former greater kinde, having many narrow hoary leaves lying on the ground, but shorter and broader then they, among which rise up divers naked short stalkes, little more then an handbreadth high, furnished from the middle almost to the toppes with many whitish greene flowers, standing more sparsedly in the spiked heads then the former, which afterwards yeeld smal seeds in husks, like unto Plantaine seede: the roote is somewhat long and hard with divers fibres at it. There is another sort hereof much lesser then the former, the leaves greener and narrower, and the heads of flowers smaller.

Alind minus.

6. *Myosuros Cauda Muris.* Mousetaile.

3. *Holosteum angustifolium majus sive Serpentaria major.*

The greater Sea Plantaine with grassie leaves.

This greater Sea Plantaine, hath a number of small long leaves, almost like grasse but that they are stiffe and hard sometime lying upon the ground, and sometime from a stemme under them raised a little higher; of a grayish or hoary green colour, and having on some of them, some small gashes on the edges, among which rise up naked stalkes about halfe a foote high, with small spiked heads, like unto Plantaine heads, set on the toppes of them, wherein is conteined such like seede also: the roote is somewhat thicke long and wooddy, with some fibres growing thereat.

4. *Holosteum angustifolium minus.*

The lesser Sea Plantaine with grassie leaves.

This lesser *Holosteum* is very like the former, but that it is smaller and scarse having any dent on the edges, and groweth much lower, not exceeding three or foure inches in heighth, having such like heads but smaller.

5. *Holosteum Creticum sive Leontopodium Creticum.*

Candy Sea Plantaine.

This *Candian* plant (which hath beene diversly named dy divers) hath from a reddish roote, somewhat great and as it were scaly at the head, growing smaller downewards, and spread into many long fibres, many long and narrow soft woolly leaves an handbreadth long, with three ribbes in each of them, among which rise up divers small and short footestalkes, about two or three inches long and covered with a soft reddish woollinesse, on every one whereof standeth a short thicke reddish woolly head, like unto a Plantaine head, having divers whitish flowers upon them, with blackish spots within them, seeming so many holes in them; which after they are past, have small browniish seede enclosed in their huskes, very like unto Plantaine seed, or the seede of *Psyllium* or Fleawort, which heads when they are full ripe, doe bend downewards to the ground, and are so drawne or bended together, that they resemble herein a Lions foote clasped together, whereof some gave it the name of *Leontopodium.*

6. *Holosteum Loniceri Cauda muris vocatum.* Mousetaile.

I might well have placed this herbe among the grasses, being undoubtedly of that tribe, but that divers authors doe joyne it with these *Holostea's* because it is in taste and property like them, take it therefore in this place. It shooteth forth divers small grassie leaves, very short, rough and hard, among which spring divers small slender stalkes, with small long blackish greene spiked heads, like unto a small Plantaine head but smaller, having white flowers on them, which quickly fade and fall away, after which there is found very small blackish seede in the long heads, which then in some are a little crooked, and in others straight resembling a Mousetaile, whereof came the name: the roote is small and threddy.

The Place.

The first groweth in divers places upon our owne coasts, and others also. The second of both sorts groweth as *Clusius* saith in many places of *Spaine*, in *Valentia* and *Salamanca. &c.* The third and fourth by the Sea side, in *Italy* as *Matthiolus* saith, in *Goritiensi agro*, and in the mountaines of *Gualdo* as *Durantes* saith, *Camerarius* saith by a lake of salt water neare *Islebia*, which is in *Germany*, I have it confidently affirmed to me that both the lesser and greater sorts grow neare the sea side in the West parts of the land, namely in all the tracts of the Marshes, neere *Ast ferry* in *Glocestershire.* The fifth in *Candy*, from whence it hath beene often sent to divers friends. The last groweth in many fertile pastures and medowes, as also on dry banckes, and by the path sides in many places of our owne land.

The Time.

They doe flower in the moneths of *Iune* and *Iuly*, and their seede ripeneth quickly after; the last which is the earlyest of them all, flowreth often in *Aprill* and almost gone in *May.*

The Names.

It is called in Greeke ὁλόστιον and ὁλόστεον *Holostium* and *Holosteum*, for it is written both wayes by many, *quasi tota ossea*, which is *per antiphrasim*, for as *Pliny* saith, *ex adverso sit a Græcis appellata, sicut fel dulce, quod sine duriti est herba nihil enim durum osseumve habet.* There hath beene much controversie among the learned writers and Herbarists about this herbe, divers diversly thinking of it, some holding one herbe to be it which another disprooveth, almost every writer framing one to himselfe, as *Lonicerus* the *Cauda Muris*, *Matthiolus* the *Gramen Iunceum*, when as before he tooke *Serpentina* to be it, and some as he saith tooke the *Pilosella minor* to be *Holosteum*, whom he contradicteth: *Lobel* the *Filix petræa Tragi. Ruellius Leucanthemum. Clusius* calleth that *Holostium Salamanticum majus*, which *Dodonæus* calleth *Plantago angustifolia albida*; and that *minus* which as he saith (and *Lobel* and *Pena* say the same) they of *Mompelier* called *Holosteum parvum. Bauhinus* includeth not onely the *Serpentinas*, or *Serpentarias* of *Matthiolus* and others, and the *Holosteum Salamanticum majus* and *minus* of *Clusius*, under the name of *Holosteum*, but the *Leontopodium Creticum* of both sorts of *Clusius*, which as he saith he set forth in his *Phitopinax* above twenty yeares, before *Clusius* set forth his *historia rariorum plantarum.* The first

first was first mentioned by *Lobel* and *Lugdunenſis*, and *Gerard* from him. The ſecond of both ſorts is called by *Cluſius Holoſtium Salamanticum majus & minus*, becauſe the learned of *Salamanca* in *Spaine*, called it *Holoſtium* as he ſaith, whom *Camerarius*, *Lobelius*, and *Lugdunenſis* doe follow. *Camerarius* in his *Matthiolus* calleth it *Holoſteum quorundam*, and *Dodonæus* as I ſaid before *Plantago anguſtifolia albida*. *Bauhinus* calleth it *Holoſteum hirſutum albicans majus*, as he calleth the leſſer *Salamanticum* of *Cluſius*, *hirſutum albicans minus*. The third *Matthiolus* called *Coronopus ſylveſtris*, and ſaith they of *Goritia* called it *Serpentina*; which ſince hath beene continued by *Dodonæus*, *Lobel* and others, *Camerarius in horto* calleth it *Plantago marina*: *Dodonæus* calleth it alſo *Plantago anguſtifolia*. The fourth is mentioned alſo by *Lobel* by the name of *Serpentina omnium minima*, and is his *Coronopi & Sedimontani media planta Maſſilienſium* alſo, for ſo he ſaith, they are both one and the ſame, and is in my judgement the *Holoſteum quorundam* of *Lugdunenſis*, although *Bauhinus* maketh theſe two ſorts to be foure ſeverall plants, with foure diſtinct titles. The fifth *Bauhinus* as I ſaid before, ſaith he ſet forth before *Cluſius* in his *Phytopinax*, and after in his *Prodromus*, under the title of *Holoſtium, ſive Leontopodium Creticum*, and includeth both the deſcriptions and figures of both the ſorts of *Leontopodium Creticum* of *Cluſius* in one, wherein I thinke he hath done rightly, whom I have followed, for although *Cluſius* hath ſet forth divers figures, as they were ſent him from divers places and perſons, yet it ſeemeth very probable, both by his owne relation, and *Honorius Bellus* his deſcription thereof, which is extant in the firſt Epiſtle of the ſaid *Bellus* to *Cluſius*, that they are both but one plant, and not two different ſorts; but as he and *Bauhinus* ſay, was ſent by *Cortuſus* to them both, by the name of *Cataname prima* of *Dioſcorides*, which *Honorius Bellus* diſprooveth in the ſaid Epiſtle. *Bauhinus* ſaith alſo he received it from *Ferrantes Emperatus* of *Naples*, by the name of *Holoſtium minus*, and from *Alpinus* by the name of *Gotne album catharticum*, and is the *Habbures* of *Camerarius*, and the *Planta plantaginis ſimilis* of *Lugdunenſis* in his Appendix. The laſt as I ſaid before, divers doe referre to theſe kindes of *Holoſtea*, as after *Lonicerus*, *Camerarius*, *Thalius*, and *Lugdunenſis*. *Bauhinus* himſelfe calling it *Holoſteo affinis Cauda muris*, and almoſt all others *Myoſcuros* or *Cauda muris*, onely *Tragus* calleth it *Coronopus ſylveſtris*. We may call all theſe herbes except the laſt, Sea Plantaines, although they grow in ſome places farre from the Sea, as well as neere it in others, for the reſemblance they have in their narrow ribbed leaves, and ſpiked heads, unto the ſmaller Plantaines or Ribbe worts, but eſpecially for their properties which being cooling and binding like unto them, are no doubt of the ſame faculty: the *Leontopodium* may be called Lions foote, or Lions claw, according to the Latine, although it juſtly be referred to theſe kinds of Plantaines. The laſt is called in *Engliſh* Mouſetaile generally, and of ſome Blood ſtrange, but I thinke corruptly from blood ſtaying, for in that faculty it is *prædominant*, all other Dialects follow the Latine name thereof.

The Vertues.

What hath beene formerly ſaid of the other Plantaines, may in ſome ſort be juſtly referred to theſe, for in their qualities of cold and dryneſſe, they are I ſaid little differing, wherein the Plantaines are excellent; and therefore it ſhall not neede to repeate the ſame things here againe, that formerly have beene there ſpoken. Onely for the third kind here mentioned, *Matthiolus* ſaith, that they of *Goritia*, who call it *Serpentina*, have uſed it to eſpeciall good purpoſe, as he himſelfe ſaith alſo, he hath found by good experience, againſt the bitings or ſtingings of Serpents eſpecially, and of the other venemous beaſts, as alſo to helpe thoſe that are troubled with the dropſie, eſpecially that which hath poſſeſſed the whole body, the Mouſetayle is cooling and drying like the Plantaine, and the Country people in ſome places of this land, apply it not only to thoſe that bleede at the noſe, by bruiſing the leaves and putting it up therein, but alſo to ſtay the much bleeding of wounds, and to heale them up.

CHAP. XIII.

Coronopus ſive Cornu Cervinum. Buckshorne Plantaine.

THere are ſome other ſorts of this herbe better knowne in theſe dayes, then they have beene formerly, which though growing in different climates, we will draw into one Chapter, and expreſſe them together.

1. *Coronopus vulgaris ſive Cornu Cervinum.* Common Buckshorne Plantaine.

This being ſowen of ſeede riſeth up at the firſt, with ſmall, long, narrow, hairy, darke greene leaves like graſſe, without any diviſion or gaſh in them, but thoſe that follow are gaſhed in on both ſides of the leaves, into three or foure gaſhes and pointed at the ends, reſembling the knagges of a Buckshorne, whereof it tooke the name, and being well growne lye round about the roote upon the ground, in order one by another, thereby reſembling the forme of a ſtarre, and therefore called *Herba Stella*; from among which riſe up divers hairy ſtalkes, about an handbreadth high, bearing every one a ſmall long ſpiky head, very like unto thoſe of the common Plantaine, having ſuch like bloomings and ſeede after them: the roote is ſingle long and ſmall, with divers fibres annexed thereunto, the taſte hereof is altogether drying like Plantaine.

2. *Coronopus Prochytæ Inſulæ*: Prickly Bucks-horne.

This differeth little from the former, but that it hath his leaves ſomewhat larger, broader, and thicker, more hairy or rough alſo, and the dents or diviſions of the leaves more ſharpe and prickly; the ſtalkes and heads are ſomewhat more rough and hairy, and differeth not in the reſt.

3. *Coronopus tenuifolius maritimus.* Small Sea Bucks-horne of *Naples*.

This ſmall Sea Bucks-horne (for I might well have made our owne Sea Plantaine, to be the greater kinde hereof, in that it hath more eminent dents on the edges of the leaves, then the other *Serpentina* of *Matthiolus*, which I might impute rather to the climate then to a differing kinde, but take it in which ſenſe you pleaſe, for neither you nor I can erre much, if we take it in either) hath many leaves lying on the ground, foure inches long, and ſo narrow that the Sea Southernewood leaves exceed them not, having on each ſide the leafe, three very long cuts or gaſhes turned inwards, all of them ſmooth and of a freſh greene colour, and not rough or hairy at all as the former, among which come up ſuch like heads, upon ſmall ſtalkes, as are in the firſt, but ſmaller,

1. *Coronopus vulgaris ſive cornu cervinum.*
Bucks-horne Plantaine.

Coronopus Ruellij.

5. *Coronopus Ruellij recta vel repens.*
Vpright or creeping Bucks-horne or Wart Creſſes.

ſmaller, as the roote is alſo: the taſte hereof is no leſſe aſtringent then the former.

4. *Coronopus maritimus minimus hirſutus.*
The ſmall hairy Sea Bucks horne.

This other little kinde, is ſomewhat like the laſt, but that the leaves being very ſmall, are not ſo finely or ſmally gaſhed on the edges, but ſtand rather like a little *Scabious*, and all hairy over: the ſtalkes likewiſe are hairy, and not much above an inch high, bearing ſmall hairy ſpiked heads like the reſt, but ſmaller, whereon appeare white flowers quickly fading.

5. *Coronopus recta vel repens Ruellij.*
Vpright and creeping Bucks-horne or Wart Creſſes.

Ruellius hath referred this ſmall plant to the ordinary *Coronopus* or Bucks-horne, for ſome reſemblance it hath thereto, although in quality much differing, which notwithſtanding divers writers have ſince *Ruellius* reckoned ſtill with the *Coronopos* or Bucks-hornes, and therefore let it alſo here paſſe in the ſame manner. It is a ſmall low herbe, yet in ſome places ſtanding more upright, but moſt uſually creeping with many long branches, and ſpreading a great way upon the ground round about: the creeping kind never riſing much above foure fingers high the other more, with divers very ſmall long and divided or cut leaves thereon, all along on both ſides of them, ſomewhat reſembling the diviſions of the former or the Garden Creſſe: the flowers are ſmall and white, comming forth at the joynts with the leaves, many ſet upon a ſmall long foote-ſtalke, one above another; after which come ſmall rough or ſharpe round huskes ſomewhat reſembling rough warts, which divide themſelves into two parts, and containe in each of them a ſmall browniſh ſeede: the roote is ſmall white and long, with many fibres thereat growing downe deepe into the ground, the taſte whereof is ſomewhat hot like Creſſes, but much milder, and is of many uſed to be eaten as a Sallet herbe, both boyled and greene with vinegar, as *Ruellius* himſelfe ſaith.

The

The Place.

The first usually groweth in drie sandy grounds, as in *Tuttle fields* by *Westminster*, and divers other places of the land: it was wont to be planted and nourished up in gardens in *Italy*, *France*, and other places, where the people more delight in greene and sallet herbes than we in this countrie doe, because it was in frequent use to be eaten by them: the second as *Columna* saith, groweth on the rockes, in the Iland *Prochyta*: the third hee saith likewise groweth in many untilled grounds in the Kingdome of *Naples* neare the sea side, and so doth the fourth, neare the sea side, but particularly in what countrie is not expressed: the last groweth every where almost round about *London*, in any moist ground, or the foote of bankes, where there is any low trench or rill, that is not continually filled with water.

The Time.

They all flower and seede in *May*, *Iune*, and *Iuly*, and their greene leaves abide fresh in a manner all the Winter.

The Names.

It is called in Greeke κορώνοπους *Coronopus*, *a corvino pede quem effigiant folia*, saith *Pena*, that is Crowfoote, whereunto the leaves are like, which name the Latines doe hold, as also *Cornu cervi*, or *cervinum*, and *Herba Stella*, both of them, from the posture of their leaves. Some also call it, *Harenaria* and *Sanguinaria* or *Sanguinalis*, the one from the place of his growing, the other from the effects or properties. There hath beene much doubt formerly, what herbe should be the true *Coronopus* of *Dioscorides*, for the name signifying a Crowes foote, deceived many, and led them into that errour, to thinke that the herbe called *Pes corvinus*, and *Pes gallinaceus* should be it; among whom are not onely the Comentators upon *Avicen*, but *Brunfelsius* also of late dayes, who carried away rather with the currant of the time, and the signification of the name, than with the opinion of others that contradicted it, and without the due examination of the herbe it selfe held this opinion, whom *Matthiolus* justly reprehendeth therefore, shewing that it was a species of *Ranunculus*, that was generally called *Pes corvinus*, and *Pes gallinaceus*, which is an exulcerating herbe, and not this *Coronopus* which *Dioscorides* maketh a sallet herbe familiarly eaten, and alloweth of *Monardus Ferrariensis* his judgement, that set downe this *Herba stelle*, or *Cornu cervinum*, to be the true *Coronopus* of *Dioscorides*. *Matthiolus* contesteth also against *Lonicerus* that tooke a kinde of grasse, called *gramen Mannæ esculentum*, and *Pentadactylon*, which hee saith was called by his countrimen *Capriola*, and *Sanguinella* in *Matthiolus* countrie, to be the *Coronopus* of *Dioscorides*; which grasse as he saith, although it hath five small spikes growing at the toppes of the stalkes, which being opened resemble in some manner, the foote of a Crow or other bird (as thereupon tooke the name *Pentadactylon*, of five fingers of a spread hand) yet this hath no divided leaves, neither is a sallet herbe for men to eate, but onely being a grasse serveth as hay for beastes: there is also another controversie among divers, what herbe *Theophrastus* should meane by his *Coronopus* (which *Gaza* translateth *Solidago*, and) which hee placeth among the prickly plants, whom *Pliny* also herein followeth in his 21. Booke and 16. Chapter; and yet in his 22. Booke making mention thereof, doth not speake of any prickles it hath, following peradventure *Dioscorides* text therein; but *Mottbiolus* to excuse *Theophrastus* his prickles in *Coronopus*, supposeth that the jagges or divisions of the leaves of *Cornu Corvinum*, might be taken or mistaken by *Theophrastus* to be thornes (he might as well say hornes) or prickles, although they be not hard nor sharpe: and therefore judgeth the *Coronopus*, both of *Dioscorides* and *Theophrastus* to be one palnt; which thing although with *Matthiolus* I thinke to be true, yet doe I not thinke his reason therefore to be true; but if I may give my judgement thereof, I thinke it more probable that *Theophrastus* might see such a *Coronopus*, as *Fabius Columna* calleth *Insulæ Prochytæ*, which hath sharpe and prickly edges; (as is before said in the description thereof) and therefore placed it *inter aculeatas*; and *Dioscorides* such as we usually have, which grew in milder places, and is a tender herbe, used to be eaten; and hereby as I thinke they may be reconciled together. The first is called *Coronopus sativus*, by *Cordus*, *Gesner*, *Camerarius* and others, and *hortensis* by *Bauhinus*, because it was familiarly sowen in gardens for meate, and *Herba Stella*, as I said before, by *Lobel*, *Dodonæus* and others, and *Cornu cervi*, and *Cornu cervinum*; yet the same herbe is also called *sylvestris*, being found wild by divers, both the same and other Authors: the second is as I said called *Coronopus Insulæ Prochytæ*, by *Fabius Columna*, and by *Bauhinus Coronopus sylvestris hirsutior*: the third the same *Columna* calleth *Coronopus Neopolitanus tenuifolius minimus*, and *minimus tenuifolius maritimus*: the fourth *Bauhinus* setteth forth under the name expressed in the title: the last is thought by some to be the *Coronopus* of *Dioscorides*; but called by some *Nasturtium verrucarium*: yet is generally called *Coronopus repens Ruellij*: but *Dodonæus* thinketh it fitter to be called *Pseudo coronopus*, or else *Cornu cervi alterum vulgi*; the upright plant is *Matthiolus* his *Ambrosia*, and *Lobels Ambrosia spontanea strigosior*, and *Bauhinus* himselfe putteth it for a second *Ambrosia*, because it is figured upright by *Matthiolus* and *Lobel*. The first is called by the *Italians Herba stella* and *Coronopo*, by the *Spaniards Guiabella*, by the *French Corne de Cerf*, and *pied de cornolle*; by the *Germans Krauwen fuss*, by the *Dutch Hertzharren*, we in *English* call it Bucks horne, Harts horne, and Bucks horne Plantane, and of some Herbe Ivye, and Herbe Eve; *Gerard* calleth it Swines Cresses, but I do rather call it Wart Cresses according to the Latine name that some give from the forme of the huskes of seede.

The Vertues.

Buckshorne Plantane boiled in wine and drunke, is an excellent remedy for the biting of a Viper or Adder (for I hold our *English* Adder to be the true Viper, both by the forme thereof, the teeth it hath with poison in the gummes, being deadly and dangerous upon the biting, and by the breeding, which is of quicke young ones, and not by egges as snakes, &c.) by laying some of the herbe to the wound: the same also being drunke, helpeth those that are troubled with the stone in the reines and kidneyes, not that it breaketh the stone or expelleth it, but by cooling the heate of the parts, and strengthening the backe and reynes: it stayeth likewise all bleedings, and eruptions of bloud, whether at the mouth or nose, either by urine or the stoole, and helpeth the laske of the belly and bowells, and the disentery or bloudy fluxe: it helpeth much also those that have weake stomackes, and are much given to casting, not containing their meate; and this the herbe doth well, but the roote more effectually. *Paulus Ægeneta* in his seventh Booke writeth, that it helpeth those that are troubled with the collicke; of which some make a doubt, that it might be an errour of the Writer in mistaking the word, but that he in the same place, presently after that he hath shewed, that the Larke is a remedy for the collicke adioyneth this also, that the rootes also of *Coronopus* doth helpe the cholicke; it hath beene held profitable for agues, to weaken their fits, and to take them away, to hang the rootes with the rest of the herbe about the necke, as nine to men, and seven

seven to women and children; but this, as many other are idle amulets of no worth or value: yet since it hath beene reported unto me for a certaintie, that the leaves of Bucks-horne Plantane laid to their sides that have an ague, will suddenly ease the fit, as if it had beene done by witcherie: the leaves and rootes also beaten with some bay salt, and applied to the wrestes worketh the same effects, which I hold to be more reasonable and proper: the herbe boyled in Ale or Wine, and given morning and evening for some time together, helpeth all sorts of sore eyes, that come by the destillation of hot and sharpe or salt rheumes, falling from the head upon them, by cooling and tempering the heate and sharpenesse, and staying the destillations. The *Coronopus Ruellij* or creeping Buckshorne being as I said a sallet herbe with many, is also thought by some, good to take away warts by a specificall propertie of the seede.

CHAP. XIV.

Ophris sive Bifolium. Tway-Blade or Herbe Bifoile.

SOme have made two or three sorts of the upland Bifoile, one greater and another lesser, one with two leaves as is usuall, another with three leaves, as if it were a differing species; but herein I thinke they are deceived, for the superfluitie of leaves in this, is no otherwise than in many others, *a lusus naturæ*, which upon transplanting every one may know that will. I shall therefore shew you the description but of one of this kinde, yet mention these other that are but as accidents in nature, and withall shew you a Marsh kinde not remembred by any before.

1. *Bifolium sylvestre vulgare.* Ordinary wood Bifoile or Twayblade.

This small herbe from a roote somewhat sweete, whose head or toppe is somewhat thicke, which some have called a Bulbe (I have therefore given you it in another figure by it selfe) shooting many long fibres downewards, raiseth up a round greene stalke, bare or naked next unto the ground, for an inch two or three to the middle thereof, as the plant is in age and growth, as also from the middle upward unto the flowers, having onely two broad and short ribbed pale greene or hoary leaves, very like unto Plantane leaves but whiter set at the middle of the stalke one on each side, and compassing it at the bottome, sometimes it will get three leaves, which thereupon some reckoned to be a different sort, which is as we call it, but *lusus naturæ* by the abundance of nourishment in the plant, as it hapneth to very many other plants, (as to the *Herba Paris* as I said before, sometimes having five leaves, and sometimes sixe or seven, and sometimes wanting a leafe, when as ordinarily it hath but foure, and so likewise in the ordinary field Trefoile, which as all know usually hath but three leaves upon a

Bifolium sylvestre vulgare seu Ophris.
Ordinary wood Twayblade or Bifoide.

Ophris Bifolia cum radice bulbosa.
Twayblade whose bulbous head is more conspicuous.

stalke,

ſtalke, yet oftentimes divers ſtalkes are found, that beare foure leaves and the like in a number of other plants which were endleſſe as well as needeleſſe to repeate) ſome alſo reckon up two ſpecies or ſorts hereof, a greater and a leſſer (but none of them mention the *Paluſtre* whereof I ſhall ſpeake in the next place) both in that which beareth but two, as alſo in that which beareth three leaves; and *Cluſius* in his *Curæ poſtoriores* mentioneth one very ſmall ſort, that the Capuchine Frier *Gregorius de Reggio* found, all which I account to be but the variation of the ſoyle and aire, and therefore I do not here diſtinguiſh them into ſo many ſeverall ſorts as they do: the flowers at the toppe of the ſtalkes are many ſmall long whitiſh greene ſhapeleſſe bodies, as it were, ſomewhat like unto ſome of the *Orchides* or *Satyrions* which paſſe away, having ſmall heads with duſt in them afterwards.

2. *Bifolium paluſtre.* Marſh Bifoile.

The Marſh Bifoile hath ſcarſe beene obſerved by any, or at leaſt hath deceived many that ſuppoſed it not to bē differing from the former, although differing in the ſite, yet the difference is manifeſt, firſt in the ſmallneſſe, being much leſſer, and having ſometimes three leaves alſo: ſecondly in the greeneſſe, the other being more hoary white: thirdly in the ſpike of flowers, which although of the ſame faſhion and colour or very neare, yet leſſe by farre: fourthly, in the rootes which in this doe runne or creepe in the ground: and laſtly, the place which is not the Woods, but Moores, Bogges, and wet Mariſh grounds.

The Place.

The firſt is uſually an inhabitant of Wood-Copſes and the likē, as betweene *Highgate* and *Hampſteede*, and in many other places of this land: the other not onely in the low wet grounds betweene *Hatfield* and St. *Albones*, but in divers places of *Romney marſh*.

The Time.

They are in flower uſually untill the later end of *May* at the ſooneſt, and ſo continue untill the middle or end of *Iune*, and then wholy will be withered and gone in *Iuly*.

The Names.

The firſt is generally thought to be the *Ophris* (*quod aliqui ſupercilium reddunt*) of *Pliny*, which he ſaith in his 26. Booke, and 15. Chapter, is an herbe like unto the dented or toothed Pot-herbe with two leaves; but what that dented Pot-herbe is, is not well knowne, and therefore it is but ſuppoſed as I ſaid, that this herbe with two leaves ſhould be it; but becauſe we know no other herbe, that hath but two leaves it carrieth the more probabilitie. *Cordus* and *Geſner in hortis Germaniæ*, have thought it to be *Alyſma* or *Damaſonium*, others to be *Gramen Parnaſſi*: *Bruſnelſius* would make it a kinde of *perfoliata*, becauſe the two leaves doe ſo compaſſe the ſtalke at the bottome, as if it were but one leafe, and that the ſtalke went thorough them, and others have thought it to be a kinde of *Helleborine*, becauſe the flowers are ſomewhat like unto it: *Dodonæus* calleth it *Pſeudo orchis, ſive Bifolium*, and *Tragus* maketh it his tenth *Satyrium*, calling it *Bifolium*, by which name it is now generally called and knowne of all Herbariſts, the other hath not beene by any before remembred: the *French* call it *Double Fueille*, the *Germans Zweyblat*, the *Dutch tweeblat*, and we Twayblade, or herbe Bifole.

The Vertues.

It is not much aſtringent in taſte, but rather clammie or glutinous, and ſomewhat ſweete, whereby it may bē judged to be hot and drie, it is much and often uſed by many and to good purpoſe for wounds, both greene and old, and for to conſolidate or knit ruptures. *Pliny* ſaith *Ophris* is good to make the haire of the eye browes blacke, but this hath not beene tried by any in our dayes, to have any ſuch effect that I know.

CHAP. XV.

Monophyllon ſive Unifolium. One blade.

Monophyllon ſive Vnifolium.
One blade.

THis ſmall plant never beareth more than one leafe, but onely when it riſeth up with his ſtalke, which thereon beareth an other, and ſeldome more, which are of a blewiſh greene colour, therein very like unto the leafe of a ſmall Lilly Convally, but ſomewhat broader at the bottome, and pointed with many ribbes or veines therein like Plantane; at the toppe of the ſtalke grow many ſmall white flowers ſtarre faſhion, ſmelling ſomewhat ſweete, after which come ſmall reddiſh berries when they are ripe: the roote is ſmall of the bigneſſe of a Ruſh lying and creeping under the upper cruſt of the earth, ſhooting forth in divers places.

The Place.

It groweth in moiſt ſhadowie and graſſie places of woods, in many places of the Realme.

The Time.

It flowreth about *May*, and the berries be ripē in *Iune*, and then quickly periſheth untill the next yeare, it ſpringeth from the ſame roote againe.

The Names.

It may be called in Greeke μονοφύλλον, after the Latines *Vnifolium*, for it is not mentioned by any ancient Greeke Author, nor yet by any ancient Latine, as is thought, unleſſe as *Dalechampius* upon *Dioſcorides* ſuppoſeth, it may be the *Cyclaminus tertia* of *Pliny* in his 25. Booke and 19. Chapter, which hee

ſaith hath but one leafe, unleſſe the place be corrupted, whereof there is ſome doubt. *Tragus* calleth it *Cotyledon ſylveſtre*, and *Vnifolium*: moſt of the later Writers call it *Monophyllon* or *Vnifolium*, onely *Bauhinus* referreth it to the *Lilium convallium*; calling it *Lilium convallium minus*, but he ſetteth it downe in his *Matthiolus*, that the *Gramen Parnaſſi* of *Matthiolus*, whom *Lugdunenſis* and others doe follow, is this *Vnifolium* ill ſet forth, which if it be ſo, then *Lobel*, *Dodonæus*, and all others, have beene utterly miſtaken in *Gramen Parnaſſi*, who all give the ſame or thelike figure of *Gramen Parnaſſi*, that *Matthiolus* doth, and even *Bauhinus* himſelfe, calleth that *Gramen Parnaſſi albo flore*, that hee ſaith, *Lobel*, *Dodonæus* and others call, *Gramen Parnaſſi*, how can it then be miſtaken, when all others and himſelfe agreeth to call it *Gramen Parnaſſi*, and not *Vnifolium* as they doe this; and indeed with what reaſon or judgement can the *Gramen Parnaſſi* be this *Vnifolium*, when this hath never more than one leafe untill it flower, and the *Gramen Parnaſſi* is never without more leaves than one: the *Germans* call it *Einblat*, and the *French Vne fueille*, as we doe One blade.

The Vertues.

Halfe a dramme or a dramme at the moſt in powder of the rootes hereof taken in wine and vinegar of each equall parts, and the party preſently thereupon laid to ſweate, is held to be a ſoveraigne remedy for thoſe that are infected with the plague, and have a ſore upon them, by expelling the poyſon and infection, and defending the heart and ſpirits from danger: it is alſo accounted a ſingular good wound herbe, and thereupon uſed with other herbes in making ſuch compound Balmes, as are neceſſarie for the curing of wounds, be they freſh and greene, or old and malignant, whereof there hath beene often and ſufficient triall made to be very availeably, but eſpecially if the nerves or ſinewes be hurt.

Chap. XVI.

Ophioglossum ſive Lingua ſerpentina. Adders tongue.

THis ſmall herbe alſo hath but one leafe, which with the ſtalke, riſeth not above a fingers length above the ground, being fat or ſomewhat thicke, of a freſh greene colour, formed very like unto the head of a broad Javelin or Partizan, or as ſome doe liken it, to the leafe of the water Plantane but leſſe, without any middle ribbe therein, as all or moſt other herbes have: from the boſome or bottome of which leafe on the inſide, riſeth up a ſmall ſlender ſtalke, about a fingers length, and ſometimes the ſmall ſtalke will have two heads thereon, and ſometime three, or elſe abortive as *Lobel* expreſſeth one; the upper halfe whereof is ſomewhat bigger, and as it were dented about with ſmall round dents, of a yellowiſh greene colour, reſembling the tongue of an Adder or Serpent, which never ſheweth any other flower, and falleth away with the leafe alſo quickly after the tongue hath appeared, without bringing any ſeede, that could be obſerved: the roote is ſmall and fibrous abiding under ground, and ſhooting forth the next Spring, not periſhing in the Winter, although the leaves doe. Some have made hereof two other ſorts, one whoſe leaves at the lower end is ſomewhat more forked than the other; and another ſmaller than it, which I doe account but *luſus naturæ*, and from the ſoyle or climate.

Ophioglossum. Adders tongue.

The Place.

It groweth in many moiſt meddowes of the land where the roote lyeth covered with the graſſe.

The Time.

It is to be found in *Aprill* and *May*, and quickly periſheth with a little heate.

The Names.

The later Writers have put the Greeke name Οφιογλωσσον *Ophioglossum* hereunto according with the Latine *Lingua ſerpentis* or *ſerpentina*, as it is uſually called now adayes, for it is not found in any of the ancient Greeke or Latine Writers, except it be the *Lingua* or *Lingulaca* whereof *Pliny* maketh mention in his 24. Booke and 19. Chapter, and in his 15. Booke and 11. Chapter, that groweth about fountaines, but becauſe he maketh no deſcription of the forme, it is doubtfull whether it be it or no; for *Lugdunenſis* referreth it to the *Ranunculus gramineus*, whereof I have ſpoken both here before, and in my former Book, and *Dalechampius* as he ſaith, would make *Pliny* his *Lingua* to be a kind of *Conyza paluſtris ſerratifolia*. Some alſo would make this to bee *Ceratia Plinij*, in his 26. Booke and 8. Chapter, which he ſaith hath but one leafe and a roote made of nodes or knottes, but ſo is not this; but as I ſhall ſhew you ſhortly, *Fabius Columna* doth moſt properly of any other, referre his *Ceratia*, to the *Dentaria Coralloide radice*. Some alſo would make it *Lunaria minor*, but we have another herbe more properly called by that name, as you ſhall underſtand in the next Chapter: *Amatus Luſitanus* calleth it *Vnifolium*, which doth well agree hereto; and *Lobel* in his *Adverſaria Eneaphyllum*; but becauſe the herbe in the Chapter next going before, is ſo called with moſt; I thinke it not convenient ſo to confound two herbes by one name, and I finde none other to follow them herein. *Brunfelſius* maketh it his *Serpentaria ſecunda*, as thinking it a ſpecies of that kinde: *Cordus* calleth it *Lingua Vulneraria*; *Geſner in hort. Lancea*

Christi, but most writers now a daies doe call it *Ophioglossum & Lingua serpentis*, or *serpentina*. The *Italians* call it *Ophiogloſſo, Herba senza costa. Lucciola, Argentino* and *langue de serpent*. The *French langue de serpent*. The *Germanes Naterzunglin*. The *Dutch Speercruijt* as *Dodonæus* saith. And we in English Adders tongue or Serpents tongue.

The Vertues.

Adders tongue is temperate betweene heat and cold, and dry in the second degree; the juice of the leaves given to drinke, with the distilled water of Horsetaile, is a singular remedy for all manner of wounds in the breast or bowels, or any other parts of the body. It is with no lesse good successe given to those that are much given to casting, or vomiting, and also to those that voide blood at the mouth or nose, or otherwise downewards; the said juice or the dryed leaves made into powder, and given in the distilled water of Oaken buds, is very good for such women as have their usuall courses, or the whites come downe upon them too aboundantly: the said powder of the herbe taken for some time together, doth cure the rupture as *Baptista Sardus* saith. The greene herbe infused or boyled in red wine, or white wine, and those eyes that are much given to water, washed therein or dropped therein, taketh away the watering, and cooleth any inflammation that commeth thereby; with the leaves hereof infused in oyle *Omphacine*, or of unripe Ollives, insolated or set in the Sunne for certaine dayes; or the greene leaves boyled in the said oyle sufficiently, is made an excellent greene oyle, or Balsame, singular good, not onely for all sorts of greene or fresh wounds, but for old and inveterate ulcers also, quickly to cure them, especially if a little fine cleare Turpentine, be dissolved therein; the same also stayeth and represseth all inflammations that rise upon paines, by any hurt or wounds.

CHAP. XVII.

Lunaria minor. Small Moonewort.

MAny Authours have set forth varieties of this small Moonewort, which because they are but from the Luxuriousnesse of the Plant, in a fertile soyle and accidentall also, not to be found constant, which should make a particular *species*. I have wholly refused to set downe many descriptions of one herbe, but sometime degenerating; let one description therefore serve instead of many, with the relation of some casualties as they happen. The small Moonewort riseth up usually but with one darke greene thicke and fat leafe, standing upon a short foote-stalke, not above two fingers breadth high, but when it will flower it may be said that it beareth, a small slender stalke, about foure or five inches high, having but one leafe set in the middle thereof, which is much divided on both sides into many parts, most usually with five or seaven on a side, yet some have beene found with nine divisions on a side, and sometimes with more, yea some have thought that it may have as many leaves or parts of leaves rather, as there are dayes in every Moone, but this is onely opinionative; each of those parts is very small, next the middle ribbe, but broad forwards, and round pointed, resembling therein an halfe Moon, from whence it tooke the name, the uppermost parts or divisions being lesse then the lowest: the stalke riseth above this leafe two or three inches, bearing many branches of small long tongues, every one very like unto the spiky head of the Adders tongue, of a brownish colour, which whether I should call them the flowers or the seed, I well know not, which after they have continued a while, resolve into a mealy dust, the rote is small and fibrous. This is sometimes found to have divers such like leaves, as are before described, with so many branches or toppes arising from one stalke, each divided from other. And *Clusius* setteth forth another, which he calleth *ramosa*, and came out of *Silesia* to him and others, which had more store of leaves, and each leafe more divided, and each part dented about the egdes, bearing divers stalkes, with branched tops like the other, which leaves, were more fat thicke and sappy, and with a little hairy downe upon them.

Lunaria minor. Small Moonewort.

The Place.

It groweth upon hils and on heathes, yet where there is much grasse, for therein it delighteth to grow.

The Time.

It is to be found onely in *Aprill* and *May*, for in *Iune* when any hot weather commeth, for the most part it is withered and gone.

The Names.

It is not certainely knowne to be remembred by any of the ancient Greeke or Latine Authors, yet some would make it to be *Ceratia Plinij* whereof is spoken before; some to be *Tragium secundum Dioscoridis*, which growing on mountaines, hath the leafe of *Scolopendrium* or Miltwaste; but the roote he saith smelleth strong, which this doth not, and therefore cannot be it, some also doe thinke it to be *Hemionitis altera* and *Selenitis*, because some take the *Hemionitis* to be *Lunaria major*. Some also as *Columna* to be *Epimedium* of *Dioscorides*, but he saith with all, that the roote hath a strong sent, which cannot agree hereunto; Some also have called it *Ophioglossum* for the likenesse of the toppes. *Clusius* saith that those of *Silesia*, where that kinde groweth, that he calleth *ramosa*, doe call it in their language, *Rechter widerthon*; that is as he saith, *Trichomanes legitimum*

legitimum, the true Mayden haire; all late writers doe call it *Lunaria minor, a foliis lunæ crescentis modo falcatis, & botrytis sive ramosa, aut racemosa, a capitibus racemi in modum formatis.* *Gesner* in *libro de lunarijs*, calleth it *Lunaria petræa*, and *Taura*, as he saith the Heardsmen and Shepherds doe, becausе if the Kine feede, where this herbe groweth, they will speedily goe to the Bull. *Tabermontanus* calleth it *Ruta Lunaria vel jecoraria.* The *Italians* call it *Lunaria del grappolo.* The *French Taure* and *Petite Lunaire.* The *Germanes Monrauten* and *Monkraut.* The *Dutchmen Maencruyt.* We in *English* Moonewort, but there are so many herbes called by the name of *Lunaria*, that it would make any man wonder how so many should be so called. *Gesner* hath collected them all or the most part, and set them forth together, in a tractate by it selfe, whereunto if any be desirous to understand them, I must referre them to him; for it were too tedious to repeate them all here.

The Vertues.

Moonewort is cold and drying more then Adders tongue, and is therefore held to be more availeable, for all wounds, both inward and outward, the leaves boyled in red wine and drunke, stayeth the aboundance of womens ordinary courses, and the whites also; it stayeth bleeding, also vomitings and fluxes; it helpeth all bruisings and beatings; it helpeth to consolidate all fractures or dislocations; it is good for ruptures; but it is chiefly used of most, with other herbes to make oyles or balsames, to heale fresh or greene wounds, either inward or outward as I said, for which it is excellent good. It hath beene formerly related by impostors and false knaves, and is yet beleeved by many, that it will loosen lockes, fetters, and shooes from those horses feete, that goe in the places where it groweth; and have beene so audatious to contest with those have contradicted them, that they have both knowne and seene it to doe so; but what observation soever such persons doe make, it is all but false suggestions and meere lyes: Some Alhymists also in former times have wonderfull extolled it to condensate or convert Quicksilver into pure silver, but all these tales were but the breath of idle headed persons, which divers to their cost and losse of time and labour have found true, and now are vanished away with them, like the aire or smoake therein.

CHAP. XVIII.

Pyrola. Winter greene.

ALthough there were formerly but one sort of *Pyrola* knowne, yet *Clusius* and some others have found out other sorts thereof, which shall be handled together in this Chapter.

1. *Pyrola nostras vulgaris.* Our ordinary Winter greene.

This ordinary (for so I call it in regard it not onely groweth in our Country, and few or none of the rest, but because it is best knowne and of most use,) Winter greene sendeth forth seaven or eight or nine leaves, from a small browniſh creeping roote, every one standing on a long footestalke, which are almost as broad as long, round pointed, of a sad greene colour, hard in handling, and like unto the leafe of the Peare tree, from whence it tooke the name, but others compare them to be like unto the small leaves of wild Beetes, which is not so proper in my mind, from whence ariseth a slender weake stalke, yet standing upright, bearing at the toppe many small white flowers, smelling as sweete as those of Lilly convally, laid open like a starre, consisting of five round pointed leaves, with many yellowish threds standing in the middle, about a greene head, and a long stile with them, which in time groweth to be the seede vessel, which when it is ripe is formed five square, with a small point at it, wherein is contained as small seede as the dust it selfe.

1. *Pyrola nostras vulgaris.*
Our ordinary Winter greene.

2. *Pyrola minor sive minima.*
The least Winter greene.

This little *Pyrola* hath the roote creeping in the same manner that the former doth, and rising up in divers places; from whence rise up divers stalkes, about two or three inches high, bare for a space, in the middle whereof are set at severall joints two or three leaves a peece, each being smaller, rounder, and thinner then the former, a little snipt about the edges, and at the toppes standeth only one flower a peece, made of five round white leaves, somewhat greater then the first, very like unto the flower of *Parnassus* grasse, having divers yellow threds in the middle, compassing a greene head, which hath a pointell thereat, parted at the toppe into five threds: the head groweth in time to be five square, with such like seede therein as are in the former.

3. *Pyrola tenerior.* Slender Winter greene.

This tender or slender Wintergreene, riseth up from a small roote like Couchgrasse, creeping divers waies under the ground with divers more weake and slender stalkes then the former, from whence grow somewhat longer pointed leaves, and dented about the edges, nothing so hard in handling, else very like the former, the stalkes have divers white flowers, standing at the toppes of them, like unto the former but smaller, as the

five

3. *Pyrola tenerior.*
Slender Wintergreene.

4. *Pyrola Europæa Alsines flore.*
The Winter greene of *Europe* with Chickeweede flowers.

5. *Pyrola Brasiliana Alsines flore major & minor.*
Winter greene of *America* with Chickeweed flowers.

6. *Pyrola fruticans.*
Shrubby Winter greene.

five ſquare heads of ſeede that follow are likewiſe, wherein is ſuch like duſty ſeede.

4. *Pyrola Europæa Alſines flore.* The Winter greene of *Europe* with Chickeweede flowers.

This ſmall Winter greene riſeth up with one or more ſtraight round ſtalkes, about halfe a foote high or better, almoſt bare of leaves for a ſpace next unto the roote, or at the moſt but with two or three very ſmall leaves, ſet one a little above another, but at the toppe thereof there groweth five or ſixe, or ſeaven or eight leaves, ſomewhat long and pointed at the end, ſomewhat like unto the leaves of the Peare tree, but longer and not ſo round, being many of them an inch and a halfe long, or more, tender, ſmooth, greene, and having one middle ribbe, with divers veines in the leafe, finely dented about the edges, from among which leaves ariſe weake footeſtalkes, rather then ſtalkes, about three inches long, ſuſteining three or foure flowers, each of them by it ſelfe, made of ſix white pointed leaves a peece ſtarre faſhion, ſomewhat like the flower of a Chickeweede, but larger, with divers ſmall yellowiſh threds in the middle; after they are paſt, there riſeth in their places one ſmall round head, ſmaller then a Coriander ſeede, conteining within it divers ſmall blacke ſeede, covered with a thinne white skinne: the roote is made of many ſmall fibres ſet together at a ſmall round head; Hereof there is found another ſort ſmaller then the other, both in leaves, ſtalkes, and flowers.

Minor. 5. *Pyrola Braſiliana Alſines flore.* Winter greene of *America* with Chickeweede flowers.

This Winter greene alſo of *Braſill* in *America*, is of two ſorts, one greater then the other: From a ſmall white roote very full of fibres, there riſeth one ſingle ſmall ſmooth ſtalke, of ſix or ſeaven inches high, without any leaves thereon up to the middle thereof, where there are two ſmall ones ſet one againſt another; but at the toppe thereof breaketh forth ſix or ſeaven leaves laid round about it, which are ſome larger and ſmaller then others: ſome being two inches long, others but an inch or an inch and a halfe long, ſmooth, tender and greene, pointed at the end, having five ribbes running thorow every one of them, like unto the Ribwort Plantaine, and not dented about the edges, from among which riſeth up a ſmall footeſtalke or two, not above an inch or two long, ſuſtaining every one of them, one ſomewhat large whitiſh yellow flower, conſiſting of ſixe narrow and pointed leaves, two whereof are ſomewhat broader then the reſt, having divers reddiſh threds in the middle.

Minor. The leſſer ſort hereof groweth ſomewhat lower, with leſſer leaves then the former, and with leſſer flowers then it alſo, but yet longer and greater then the greater of the *European* kinde.

6. *Pyrola fruticans.* Shrubby Winter greene.

Although this plant be no ſhrubbe of any hard wooddy ſubſtance; yet becauſe the ſtalkes be hard abiding long, and encreaſing every yeare without withering or dying, it is called ſhrubby, therein comming neereſt unto the nature of a ſhrubbe: it riſeth up with divers limber ſtalkes, which for ſome yeares remaine firme and upright, but after they be growne elder, that they are laden with leaves, the waight of them doth beare them downe to the ground, wherein ſometimes they take roote againe, theſe ſtalkes have at every joynt two three or foure fat fleſhy leaves of a deepe ſhining greene colour, ſomewhat like to the leaves of the Strawberry tree, both for forme and bigneſſe, but dented about the edges: from the middle whereof ariſe certaine buds, made as it were of ſmall ſcaly heads, which turne into ſmall twigges, whereon are ſet three or foure or five flowers a peece, of a whitiſh purple colour, ſomewhat bigger then the flowers of the firſt *Pyrola* or Winter greene, after the flowers are paſt come five ſquare heads, containing very ſmall ſeed: the roote is ſlender with ſome ſtrings annexed thereunto, and creepeth farre abroad under the ground.

The Place.

The firſt ſort groweth in our owne land, yet but in very few places, and thoſe *Northwards*, in *Yorkeſhire*, *Lancaſhire*, and further *North*, yea even in *Scotland*, in the woods every where, and ſeldome in fields. The ſecond groweth at the foote of the high hils in *Auſtria* and *Stiria* as *Cluſius* ſaith. The third in *Germany*, as alſo neere *Savoy*. The fourth groweth in the woods of *Germany* in divers places, as alſo in the Beeche wood in *Scotland*, as it is recorded by *Bauhinus*, who ſaith Dr. *Craige* ſent it him from thence, and on the mountaines in *Wales* likewiſe. The fifth; of both ſorts groweth in *Braſile*, towards the *Weſt Indies*. The laſt groweth in moſt of the Provinces of *Hungary*, *Germany*, and *Bohemia*.

The Time.

They doe all flower except the *American* ſorts about *Iune* and *Iuly*, but the other more late with us.

The Names.

It is called *Pyrola* in Latine (for it hath not found any Greeke name) *a foliorum pyri arboris, & florum etiam ſimilitudine* of the likeneſſe of the leaves, and I may ſay of the flowers alſo, unto Peare tree leaves and flowers, divers have taken it to be *Limonium*, as *Fuſchius*, *Lonicerus*, *Tragus*, and *Cordus* alſo, who calleth it *Beta ſylveſtris*, but the true *Limonium* is now ſo well knowne, that it putteth all out of doubt, and ſome would make it to be *Brittanica Plinij*, whereunto it hath no reſemblance, but is generally of all now adaies called *Pyrola*, and *vulgatior*, becauſe the reſt are rarer to be found. The ſecond *Cluſius* calleth *Pyrola minima*, and *Bauhinus Pyrola rotundifolia minor*. The third is called by *Cluſius Pyrola tenerior*, by *Camerarius Pyrola Pannonica ſecunda*, by *Thalius Pyrola minor*, by *Dalechampius* upon *Dioſcorides*, and by *Lugdunenſis Ambroſia montana*, and by *Bauhinus Pyrola folio mucronato ſerrato*. The fourth is called by *Cordus in obſervationum ſylva*, *Herba Trientalis* by *Schwenckfeldius Alſine Alpina*, by *Thalius Alſinanthemos*, *id eſt*, *Alſines flos*, and by *Bauhinus* *Pyrola Alſines flore Europæa*, to diſtinguiſh betweene it and the next, which he calleth *Pyrola Alſines flore Braſiliana* and *Americana*, and doth much reſemble the *Polyrrhizos latifolia* of *Lugdunenſis* in my opinion, although *Bauhinus* referreth it to *Cariophyllata pentaphyllea*. The laſt is called by *Cluſius* *Pyrola fruticans* or *fruteſcens*, and *Bauhinus* *Pyrola fruteſcens Arbutifolio*. It is called by the *Italians* *Pyrola*, by the *French* *Pyrole*, by the *Germanes Wintergrun* and *Hoſtzmangolt*, and *Waldmangolt*, after the name of *Beta ſylveſtris*, or *Limonium*, by the *Dutch Wintergroen*, and in *Engliſh* Wintergreene.

The Vertues.

Wintergreene is very cold and drying and exceeding aſtringent, and glutinous withall, whereby it is a moſt ſingular remedy for greene wounds, to conſolidate their lippes ſpeedily together, either the greene leaves bruiſed and applyed of themſelves, or the juce of them, or a ſalve made of the greene herbes ſtamped, or the juice boyled with *Axungia* or Hogs lard, or with ſallet oyle and waxe, and ſome turpentine added unto it; which is ſo ſoveraigne a ſalve for all manner of wounds and ſores, that the *Germanes* uſe it exceeding much, and extoll it beyond

beyond any other ſalve made of a ſimple herbe: they likewiſe uſe it for inward wounds or hurts, being boyled either by it ſelfe, or with other wound herbes, as Comfrey, Mouſeare, Burnet, Perywinkle, Tormentill, Horſe-taile, Avens, Ladies Mantle, Betony, Agrimony, Madder rootes, and Golden Rodde, and the like, wherewith they uſe to heale whomſoever is wounded, either in the body or bowells or any other part, by giving them to drinke of ſuch a decoction; the herbe boyled in wine and water and thereof given to drinke to them that have any inward ulcers in their kidnies, or neck of the bladder, doth wonderfully help them; it ſtaieth alſo all fluxes, whether of bloud or of humors, as the laske, bloudy fluxe, or womens too abundant courſes, as alſo the bleeding of wounds, and both taketh away any inflammation riſing upon the paines of the heart, and hindereth any to ariſe being preſently applied after the hurt received: it is no leſſe helpefull for foule ulcers hard to be cured, as alſo for cancres or fi ulaes: the diſtilled water of the herbe doth effectually performe the ſame things, and ſome keepe the dried herbe to uſe in decoctions, or made into powder to drinke.

CHAP. XIX.

Cynogloſſum. Hounds tongue.

Ioſcorides maketh mention but of one ſort of *Cynogloſſum* or Hounds tongue, which is generally thought to be that which is ordinary with us, but there hath beene of late dayes, divers other ſorts fonnd out, all which ſhall be here ſet downe together.

1. *Cynogloſſum majus vulgare.* The ordinary great Hounds tongue.

The great ordinary Hounds tongue hath many long and ſomewhat narrow, ſoft, or as it were hairy darkiſh green leaves lying on the ground, ſomewhat like unto the leaves of Bugloſſe, from among which riſeth up a rough hairy ſtalke, about two foote high, with ſome ſmaller leaves thereon then grow below, and branched at the toppe into divers parts, with a ſmall leafe at the foote of every branch, which is ſomewhat long with many flowers ſet along the ſame, which branch is crooked or turned inwards, before it flowreth and openeth by degrees, as the flowers doe blow, which conſiſt of foure ſmall purpliſh red leaves, ſomewhat of a ſad or dead colour, ſcarſe riſing or ſhewing themſelves, out of the rough greene huskes wherein they ſtand with ſome threds in the middle; this hath beene ſometimes found with a white flower: after the flowers are paſt there come in their places rough flat ſeede, with a ſmall thread or pointell in the middle, eaſily cleaving to any garment that it toucheth, and are not ſo eaſily pulled off againe: the roote is blacke, thicke, and long, tough or hard to breake, and full of a clammy juice, ſmelling ſomewhat ſtrong, or of an evill ſent, like as the leaves doe, which ſome doe call a ſoporiferous ſent. *F'ore alſo.*

2. *Cynogloſſum maximum.* The greateſt Hounds tongue.

This kinde differeth not from the former, either in leafe, flower, or ſeede, but onely that in them all it is neere twiſe ſo large which maketh the difference.

3. *Cynogloſſum maximum montanum.* The great mountaine Hounds tongue.

This great mountaine Hounds tongue hath alſo many large but hairy and ſoft leaves, lying on the ground, above a foote long, and an hand bredth broad, of a whitiſh greene colour, having every one the middle ribbe reddiſh; with many greene veines running thorough them, and reddiſh footeſtalkes to ſuſtaine them, thoſe which are in the middle of them ſtanding more upright; from amongſt which riſeth a thicke hollow creſted, reddiſh, woolly, or hairy ſtalke, two foote high and above ſtored on all ſides with ſuch leaves, but leſſer and leſſer up to the toppe, where it breaketh forth into foure or five branches of flowers, ſtanding all on one ſide, yet forming at the firſt a round head, very pleaſant to behold for the varietie of colours therein: the hairy ſtalkes of the flowers being greene ending in five points, the flowers hollow and long conſiſting of five purpliſh red leaves, ſomewhat ſweete, ſtanding above the flowers and greene leaves among them with red ribbes in them, which in the ſhadow where it delighteth to grow, is the more conſpicuous and beautifull; after which in the ſaid huskes come larger ſeede than the former, foure uſually together, which on the upperſide are flat circled about with a few ſhort prickes, whereby it cleaveth faſt to garments: the roote is blackiſh on the outſide, and whitiſh within, ſomewhat like the former.

4. *Cynogloſſum medium montanum anguſtifolium.* Narrow leafed hoary mountaine Hounds tongue.

This Hounds tongue hath many ſoft woolly, or hoary long and narrow leaves ſtanding upright and not lying upon the ground, being halfe a foote long, and an inch broad in the middle, but ſmall at both ends, whoſe middle ribbe, and footeſtalke are both reddiſh: the ſtalke riſeth up to be ſomewhat more, then halfe a fooote high, repleniſhed ſo thicke with ſuch like leaves as grow below, that no part of the ſtalke can be ſeene, each whereof are more hairy or woolly, and compaſſe

1. *Cynog oſſum majus vulgare.*
The ordinary great Hounds tongue.

the

3. *Cynogloſſum maximum montanum.*
The greater mountaine Hounds tongue.

5. *Cynogloſſum ſemper virens.*
Ever greene Hounds tongue.

6. *Cynogloſſum ſubrubente verſicolore flore.*
Hounds tongue with party coloured flowers.

7. *Cynogloſſum Creticum latifolium.*
Broad leafed Hounds tongue of *Candy*.

8. *Cynogloſſum Creticum anguſtifolium.*
Narrow leafed Hounds tongue of *Candy*.

10. *Cynogloſſum flore cæruleo.*
Small Hounds tongue with blew flowers.

the ſtalkes at the bottomes of them, and ſharpe at the point: on the toppe of the ſtalke ſtandeth a round hoary head, of the bigneſſe of a reaſonable apple, which opening it ſelfe, ſheweth forth many woolly leaves, with red ribbes, ſtanding at the foote of the branches and ſtalkes of flowers, which are of an excellent vermillion red colour, ſtanding in larger and more woolly huskes, and are more laid open like a ſtarre, ſtanding on both ſides of the ſtalke, and not all on ſide as the laſt: the ſeede that followeth is ſmaller and not ſo rough, with a ſmaller hollow middle: the roote is thicke and long, with a thicke blackiſh barke, on the outſide, and a hard wooddy pith in the middle, of an unpleaſant taſte as the leaves, bitter and aſtringent and hairy at the head, which are the ribbes of the withered leaves: the roote ſpringeth afreſh before Winter, after the leaves and ſtalkes are all dre and withered.

5. *Cynogloſſum ſemper virens.* Ever greene Hounds tongue.

This Hounds tongue doth not much differ, from the common or ordinary ſort, but that the leaves are alwayes freſh and greene, ſomewhat long and narrow with a great whitiſh greene ribbe in the middle, ſmooth on the upperſide, and more hoary underneath: the ſtalke at the firſt is but low, with many narrow long leaves, compaſſing it about, but more thinnely than in the former: the flowers are red, but ſomewhat larger than the ordinary, ſtanding in the like manner upon ſmall branches that are writhed or turned like the *Heliotropium*, or the firſt kinde: the ſeede that followeth ſtandeth all on the one ſide, and is ſmaller and leſſe rough, but the ſtalke is then growne much higher: the roote is blackiſh, as the other: This hath no manner of hoarineſſe, or isof ſo ſtrong a ſent as the laſt, and doth ſpring forth with freſh leaves, before the old ſtalke with ſeede is quite drie and withered.

6. *Cynogloſſum ſubrubente verſicolore flore.* Hounds tongue with party coloured flowers.

This beautifull and rare Hounds tongue, from a ſmall ſlender wooddy roote, ſhooteth forth divers heads, of ſoft hairy and ſmaller leaves than the laſt: the ſtalke riſeth up a foote and a halfe high, ſet on both ſides, with the like ſmaller leaves than thoſe below, the toppe whereof is parted into three branches of flowers, which are ſmaller than the laſt, but of a bluſh colour, ſtriped with long bloud red ſtrakes, having the bottomes of them of a deeper bluſh: the ſeede ſtandeth in the ſame manner that others doe foure together in a huske, but they have the middle ſomewhat raiſed up, and ſmall at the toppe, with a pointell thereat, and a large thinne circle or liſt about them.

7. *Cynogloſſum Creticum latifolium.* Broad leafed *Candy* Hounds tongue.

This *Candian* hath for the firſt yeare of the ſpringing many leaves lying on the ground, ſomewhat broad and not very long, with a long foote ſtalke to every one of them, ſoft, and covered with a whitiſh ſhining woollineſſe, almoſt like ſilver, and a thicke whitiſh ribbe in the middle: but the next yeare after, the ſtalke riſeth from the middle of them, ſet here and there with ſhorter leaves compaſſing it at the bottome, and ſo ſmaller up to the toppe: this ſtalke is branched from the middle upwards into divers others, that are crooked or writhed inwards,

opening

opening by degrees as the flowers blow, which are ſhort but ſomewhat large, ending in five round leaves, of a whitiſh colour at the firſt, with bluſh edges, and in ſome with pale purpliſh veines or ſtripes, which afterwards decaying grow wan or blewiſh, ſtanding in hoary cuppes, wherein after they are paſt, the ſeede groweth foure joyned together, rough and cleaving to garments as in the reſt, with a pointell in the middle: the roote is woody, and periſheth after it hath given ſeede, ſpringing from the ſeede that falleth of it ſelfe, but while it is young of the firſt yeare, is ſomewhat like unto others, not ſo thicke or fleſhie and blackiſh on the outſide, of an evill or unpleaſant ſent, as the reſt of the plant is.

8. *Cynogloſſum Creticum anguſtifolium.* Narrow leafed *Candy* Hounds tongue.

This other *Candian* hath divers long and narrow leaves, ſomewhat broad at the end, and round pointed of a whitiſh greene colour, lying next to the roote upon the ground; from among which riſeth up a ſtalke, in ſome plants higher, in others lower, whereon grow without order, ſuch like leaves but ſhorter and leſſer, compaſſing it at the foote of them: from the middle whereof upwards, it ſpreadeth into branches, bearing ſuch like flowers as are in the ordinary ſort, ending in five leaves, but of a paler red colour, with each of them five darke red threds in the middle: the ſeede and roote is ſomewhat like the ordinary, but hath no evill ſent like it or the laſt: this periſheth every yeare, and is ſowed or riſeth of the fallen ſeede againe.

9. *Cynogloſſum minus ſive puſillum,* Small Hounds tongue.

This ſmall Hounds tongue that groweth with us in divers places of our land, is not much differing from the greater ordinary kinde, but is ſmaller in all things, having ſuch like leaves ſmaller and ſhorter, but greener and more ſhining: the flowers alſo being ſmall, are of a pale red colour, and the whole plant hath not ſo ſtrong or evill a ſent: this might be thought to be thus ſmall from the barenneſſe of the ſoyle wherein it doth grow, but that is not ſo, for it is often found in the ſame grounds where the greater groweth, and beſides being either tranſplanted, or the ſeede ſowen in gardens, it wil ſtill continue much ſmaller than the other.

10. *Cynogloſſum minus flore cæruleo.* Small Hounds tongue with blew flowers.

This other ſmall Hounds tongue ſendeth forth from a ſmall long but annuall roote, one round ſmall hairy ſtalke, ſometimes but a foote, and ſometimes two foote high, browniſh below and greene above, whereupon are ſet on both ſides without order, divers ſmall and ſomewhat long but narrow leaves, of a blewiſh greene colour, covered with a long hairy down, that is tough and ſticking, the middle ribbe being ſomewhat great and eminent, of a hot bitter taſte; from the bottome of theſe leaves, eſpecially upwards, come forth ſometimes other ſmaller leaves in a tuft together, and is parted into divers branches, the toppes whereof are bended, as in divers other ſorts, bringing forth very ſmall flowers, of a faire blew colour, with a yellow ſtarre in the bottome, ſtanding in ſuch like huskes, wherein after they are paſt is contained very ſmall roundiſh ſeede, without any pricke in the middle, as others have, but very rough or prickly, ready to ſticke upon any garment, as others will.

The Place.

The firſt groweth in moſt places of the land, in waſt grounds and untilled places, as by high wayes ſides, lanes, and hedge ſides: the ſecond in the *Low Countries*, eſpecially in their gardens: the third on the mountaines of *Naples* to the *South*ward: the fourth on the ſame hills to the Northward: the fift in the ſhadowie woods on the hills in *Germany* and *Naples* alſo: the ſixt groweth onely at the foote of a certaine hill in *Naples*, to the Southwards, as *Columna* ſaith, who there obſerved it: the ſeventh as by the name it ſhould ſeeme, is originally of *Candie*, from whence being brought into *Italy*, hath from thence beene communicated to many countries: the eight not onely in *Candy*, but on the hills of *Naples* alſo: the ninth is found in *Germany*, as well as in our owne land, being mentioned by *Cordus* upon *Dioſcorides*, and it may be is that kinde that is ſaid in the *Adverſaria* to grow about *Mompelier*, and called *Puſillum Narbonenſe*: the laſt groweth in *Auſtria* as *Cluſius* ſaith, and in other parts of *Germany* as *Tragus* ſaith, in *Naples* alſo as *Columna* ſaith.

The Time.

They all flower about *May* and *Iune*, and the ſeede is ripe not long after.

The Names.

It is called in Greeke Κυνόγλωσσον, and Κυνόγλωσσος, *Cynogloſſum* and *Cynogloſſos*, *ideſt*, *Canina lingua*, *a folijs caninam linguam imitantibus*. There hath beene great controverſie among divers the learned Writers of our time, whether the *Cynogloſſum* that is here firſt ſet downe, and is the moſt ordinary in all countries, and therefore called *vulgare*, ſhould be the *Cynogloſſum* of *Dioſcorides*, becauſe he ſaith it beareth neither ſtalke nor flowers, which this doth; among whom wee muſt account *Matthiolus* to be one, who ſaith he found in ſome ſandy grounds in *Rome*, behind or beyond *Adrianus* Mount the true *Cynogloſſum* of *Dioſcorides*, whom *Pena* and *Lobel* in their *Adverſaria*, doe both taxe of want of knowledge of the true *Cynogloſſum Dioſcoridis* (for ſay they it doth in the ſame and other places beare both ſtalke and flowers; although in divers yeares and places it doth not beare, yet will beare after ſome reſpite of time in any place, as not onely they but divers other good authours have acknowledged as well herein, as in other plants; and we our ſelves have often found divers plants of the firſt kinde of Hounds tongue, not to beare flowers in the ſame places that others have the ſame yeare, and therefore by the beſt *Herbariſts* in theſe dayes, there is now no doubt, but that the common kinde is the right) as alſo that hee knew not that this his *Cynogloſſum Dioſcoridis*, is *Lycopſis*, that ſometimes doth not beare flowers, bnt reſteth without ſtalke, as hath been obſevred oftentimes, as well herein as in *Onoſma* ſtone Bugloſſe: the next that oppoſe this truth, is *Ruellius* & *Fuſchius*, who ſay that this *Cynogloſſum*, which was then uſed by Apothecaries, in *Germany* and other places as the right was not the true kind of *Dioſcorides* but rather *Lycopſis* Wall, Bugloſſe, whereof we ſhall ſpeak hereafter, againſt whom *Cordus* upon *Dioſcorides* and *Matthiolus* alſo do conteſt, *Cordus* acknowledging that *Cynogloſſum* to be right, for the reaſons before ſet downe, and *Matthiolus* ſimply coting it as an errour in them, and judging the *Lycopſis*, for the red rootes ſake, and other things therein, to be a kinde of *Anchuſa*, and alſo accounteth this common kinde, to be the ſecond *Cynogloſſum* of *Pliny*, in his 25. Booke and 8. Chapter (for his firſt kinde that is fit to make Arbors, or Imagery hedges, is not yet knowne what is is) which beareth ſmall burres, and of the beſt Writers and Herbariſts now adayes is accounted the eight kinde here ſet forth: *Lacuna* alſo calleth it *Lycopſis*. There is an errour likewiſe in *Ætius* which *Dodonæus* noteth, in making *Limonium* and *Cynogloſſum*, to be both one plant. And another in *Rondeletius*, who tooke *Glaſtum ſylveſtre*, which differeth very little from the *Sativum*, to be *Cynogloſſum*: and laſtly *Lugdunenſis*, who ſetteth the *Plantago media* or *anguſtifolia*,

ſtifolia, to be the *Cynogloſſum Dioſcoridis*, calling it *Cynogloſſum quorundam*. The firſt is generally called by all Authors, either *Cynogloſſum*, or *vulgare*, or *Cynogloſſa vulgaris*: the ſecond is but onely mentioned by *Lobel* in his obſervations, under the title of *Cynogloſſum maximum*: the third is called by *Fabius Columna*, *Cynogloſſa montana maxima frigidarum regionum*, and by *Bauhinus Cynogloſſum ſylvaticum rubente caule*, becauſe he thinketh it is the ſame that *Thalius* in *Harcynia ſylva*, calleth *Cynogloſſum ſylvaticum Harcynicum*, and the *Cynogloſſum montanum* of *Cæſalpinus*: the fourth is called by *Fabius Columna Cynogloſſa media montana incana anguſtifolia altera*; & by *Bauhinus Cynogloſſum globoſo flore*: the fift is called by the ſaid *Columna*, *Cynogloſſa media virente folio*, & by *Bauhinus Cynogloſſum ſemper virens*: the ſixt is alſo called by *Columna*, *Cynogloſſa altera media fructu cotylodes, ſive Lychnodes*; and by *Bauhinus Cynogloſſum fructu umbilicato*: the ſeventh is called by *Cluſius*, *Cynogloſſum Creticum ſecundum*, and by *Bauhinus Cynogloſſum Creticum latifolium fœtidum*: the eight is called alſo by *Cluſius Cynogloſſum Creticum primũ*, by *Camerarius in horto Cynogloſſum parvum cinereum Creticum*, by *Columna Cynogloſſa media argentea Apula campeſtris*; and by *Bauhinus Cynogloſſum Creticum argenteo folio*: the ninth is mentioned by *Cordus* upon *Dioſcorides*, and by *Lobel* in his *Adverſaria*, calling it *Cynogloſſum puſillum Narbonenſe*, whom *Lugdunenſis* followeth: the laſt is very much confounded by *Bauhinus* in his *Pinax* for his eight ſpecies, which he calleth *Cynogloſſum medium*, and ſaith it is the ſame that *Cordus* upon *Dioſcorides* calleth *Cynogloſſa minor*, and *Camerarius Cynogloſſum Italicum*, and *Lobel*, *Lugdunenſis*, and *Eyſtetenſis* call *Cynogloſſum puſillum Narbonenſe*, who all ſay that it is like the ordinary great one having ſuch like red flowers; and yet he maketh the ſame to be *Cluſius* his *Cynogloſſum pumilum ſive Auſtriacum alterum*, and alſo *Columna* his *Cynogloſſa minor montana ſerotina altera Plinij*, who both ſay that theirs have blew flowers, as the *Elatine* of *Tragus*, and the *Lappula ruſticorum* of *Lugdunenſis*, which are both one and the ſame with it; this alſo *Bauhinus* himſelfe maketh his tenth ſpecies, calling it *Cynogloſſum minus*, and there alſo making it to be the ſame *Cynogloſſa Plinij* of *Columna*, before ſet downe; ſo that he confoundeth them much, maketh that ſort with red flowers, to be the ſame with that of *Tragus* and *Lugdunenſis* which hath blew flowers, and doth correſponde altogether with theirs, which errour in him is uſuall in many other places of his *Pinax*, and not in this onely. It is called by the *Italians Cinogloſſa*, and *Lingua di cane*, by the *Spaniards Langua de perro*, by the *French Langue de chien*; by *the Germans Hundſs zungin*; by the *Dutchmen Honts tonghe*; and we in *Engliſh* Hounds tongue generally, or of ſome Dogges tongue.

The Vertues.

Hounds tongue is temperately cold, drying and aſtringent, and yet hath a mollifying qualitie. The roote is very effectually uſed in pills as well as in decoctions orotherwiſe, to ſtay all ſharpe and thin defluxions of rheume, from the head into the eyes or noſe, or upon the ſtomacke or lungs, as alſo for coughs and ſhortnes of breath; for which purpoſe the *Pilulæ de Cynogloſſa*, either of *Meſues* or *Trallianus* deſcription, or as it is corrected by *Fernelius*, is ſingular good, which is ſet downe in this manner, Take of *Myrrhe* five drammes, *Olibanum* ſixe drammes, of *Opium*, of the ſeedes of white Henbane, and the barke of the dried rootes of Hounds tongue of each foure drams or halfe an ounce, of Saffron and Caſtor of each one dramme and a halfe; let all theſe be made into a maſſe or lumpe for pilles, according to art, with the ſyrupe of *Stæchados*, the leaves boiled in wine, ſaith *Dioſcorides*, but others do rather appoint it to be made with water, and to add thereunto oyle and ſalt, mollifieth or openeth the belly downewards: the ſame alſo taken doth helpe to cure the biting of a mad Dogge, and applying ſome of the leaves alſo to the wound: the leaves bruiſed, or the juice of them boyled in *Axungia*, that is Hogges larde, and applied, cureth the falling away of the haire, which commeth of hot and ſharpe humours: the ſame alſo is a very good remedy, to apply to any place that is ſcalded or burnt with fire: the leaves of themſelves bruiſed and laid to any greene wound, doth heale it up quickly: the ſame ointment aforeſaid with a little Turpentine added thereunto, as alſo the juyce uſed with other fit things, doth wonderfully helpe all old ulcers and deepe or much ſpread ſores, in the legges or other parts of the body, and taketh away all inflammation that riſe about them, or any where elſe in the body, be it St. *Anthonies* fire or the like: the roote likewiſe baked under the embers, either wrapped in paſte or wet papers, or in a wet double cloth, and thereof a ſuppoſitory made and put up into the fundament, or applied to the fundament, doth very effectually helpe the painefull piles or hemorrhoides: the diſtilled water of the herbe and rootes is very good to all the purpoſes aforeſaid, to be uſed as well inwardly to drinke, as outwardly to waſh any ſore places, for it doth heale all manner of wounds, or punctures, and thoſe foule ulcers that riſe by the *French* Poxe.

CHAP. XX.

Anchuſa. Alkanet.

THere are divers ſorts of Alkanet, whereof I have given you the deſcription of one, and under it have made mention of ſome other ſorts in my former Booke; but becauſe I there did not ſhew you them at the full; I will in this place make further mention thereof, with the reſt of it is kinde.

1. *Anchuſa lutea major.* The greater yellow Alkanet.

This yellow Alkanet hath many long and narrow hoary leaves lying on the ground, and thicke ſet on the ſtalkes likewiſe, which riſeth not much above a foote and a halfe high, at the toppes wherof ſtand many yellow flowers, with a ſmall leafe at the foote of every flower, which are ſomewhat long and hollow, very like unto Comfrey flowers, but a little opening themſelves at the brimmes, like unto Bugloſſe flowers, with a pointell in the middle: after they are paſt there come in their places, ſmall long blackiſh ſeede, not unlike both to Bugloſſe and Comfrey ſeede: the roote is of the bigneſſe of ones finger, and of the length of two, whoſe outward barke is ſomewhat thicke, and of an excellent orient red colour, ready to colour their hands and fingers with its red colour that ſhall handle it, the inner pith being white and wooddy: the whole herbe is of an aſtringent taſte.

2. *Anchuſa lutea minor.* The leſſer yellow Alkanet.

This ſmall Alkanet is very like unto the former, but that the leaves are narrower, and not ſo long, yet covered with

1. *Anchusa lutea major.*
Th great yellow Akanet.

2. *Anchusa lutea minor.*
The lesser yellow Alkanet.

3. *Anchusa minor purpurea.*
Small Alkanet with purple flowers.

5. 6. *Anchusa arborea & Anchusa humilis.*
Tall and low Alkanet.

with an hairy hoarineſſe, as the ſtalkes are alſo, which in ſome are but a foote, in others a foote and a halfe high, with ſmaller leaves thereon: the flowers are hollow and yellow like the other, but leſſer; the ſeede alſo is alike: the roote is great in reſpect of the plant, red and tender while it is young, but growing wooddy when it is old, and blackiſh, but liveth and abideth after ſeed time, which ſome others doe not.

3. *Anchuſa minor purpurea.* Small Alkanet with purple flowers.

The ſmall purple Alkanet hath greater and longer leaves then the laſt, hairy and greene like unto Bugloſſe, and ſomewhat like unto the firſt; but yet leſſer and narrower, although more plentifull, that lye upon the ground, and thoſe alſo that riſe up with the ſtalkes, which are many, tender and ſlender, whoſe flowers being like the others, are of a reddiſh purple colour: the ſeede following is more gray; the roote is greater and thicker then the other. We have another ſort hereof, whoſe ſmall flowers ſcarſe riſing out of the huskes, are of a ſad or dead red colour, the ſeede blackiſh riſing againe yearely of its owne ſowing, and leaning downe to the ground. *Altera ſupina atro purpureo flore.*

4. *Anchuſa lignoſior anguſtifolia.* Wooddy Alkanet.

This ſmalleſt Alkanet, which ſcarſe deſerveth to be accounted one of them, both for the want of colour in the roote, and the hardneſſe of both rootes and ſtalkes; for the ſtalkes are ſcarſe a foote high, hard and wooddy, having many ſmall and narrow ſad greene hairy leaves, much ſmaller and ſhorter then the laſt, the flowers ſtand on crooked ſtalkes, bending inwards like *Heliotropium*, and are hollow but ſmaller then the former, and of a very blew colour like unto them, for the forme and manner of growing, the roote is hard and wooddy, brown ſhred on the outſide, and not colouring the hands with any red colour, or very little, ſuch as the reſt doe.

5. *Anchuſa humilis Cretica.* The low Alkanet of *Candy*.

From a ſmall long reddiſh roote of a fingers bigneſſe, ſpring ſmall ſtalkes halfe a finger long, bearing thereon many ſmall white leaves on each ſide of them, ſet very thicke together, like but leſſe then the other Alkanets, at the toppes whereof ſtand reddiſh flowers inclining to purple, larger then thoſe of Alkanet, and formed like thoſe of baſtard Sena, after which come ſmall long rough veſſels, containing within them the ſmall ſeede: in the Summer time the roote will give a red juice, that will die their fingers that touch it, which is much commended by the natives, to be ſingular good againſt the poyſon of any Serpent.

6. *Anchuſa arborea.* Great and tall Alkanet.

The roote of this Alkanet is inſipide, wooddy, long, and of a fingers thickneſſe, ſomewhat reddiſh within, and with a thinne blackiſh rough barke without; the ſtalke is thicke and rugged, ſhooting forth divers branches, and they other ſmaller, with many ſmall leaves like Savory ſet together at the joynts, and ſmall white prickes about them, but on the ſmaller branches they ſtand ſingle for the moſt part, one above another at equall diſtances, at the ends whereof grow ſmall flowers, ſomewhat like unto the ordinary Alkanet, of a yellowiſh purple colour, and the like ſeede ſucceeding, and is not of any knowne uſe

The Place.

The firſt groweth both in *Italy*, *Spaine*, and *France*, as well neare the Sea as further of into the land. I have not yet heard of any that have ſeene it growing any where in our Country. The ſecond *Columna* ſaith groweth in *Naples*. The third about *Mompelier* and *Lions*, as *Lobel* ſaith, and this I thinke is the ſame that groweth in our Country, namely in *Kent* neare *Rocheſter*, in a field neare Sr. *Iohn Leveſon* his houſe, and in ſome other places thereabouts: as alſo in the Weſt parts, as *Devonſhire*, and *Cornwall*, as it hath beene affirmed. The fourth alſo about *Marſeilles*, and *Frontignana* as *Pena* ſaith, the two laſt in *Candy*.

The Time.

They flower in *Iuly* for the moſt part; and ſometimes in *Auguſt*, but their rootes have their braveſt colour in *Iuly* and *Auguſt* or thereabouts.

The Names.

It is called in Greeke ἄγχουσα *Anchuſa* παρὰ τὸ ἀγχεῖν, *quod vim ſuffocatoriam habet, ut aliqui volunt, ſed alij melius & verius a Græco verbo* ἀγχουζειν *quod eſt fucare & colorare formam, & eo derivatum nomen ab radicis ſanguineum floridum ve colorem*; for the beautifull red colour in theſe rootes, hath not onely made them knowne, but diſtinguiſhed from *Echium*, *Lycopſis*, *Bugloſſum*, and the reſt that are like unto them in leaves, but want that colour in their rootes; ſome have called it *Alkanna* but very falſely, others *Fucus herba*. The firſt is thought to be the third kinde of *Anchuſa*, whereof *Matthiolus* giveth a figure, although he ſaith that all the *Anchuſa's* that were knowne to him, bore purpliſh flowers: it is called *Pſeuda anchuſa* by *Dodonæus*, and is the ſame *Anchuſa exalbido flore*, that *Cluſius* ſetteth forth in his Hiſtory of Plants; it is alſo very likely to be the ſame, that *Cordus* upon *Dioſcorides* maketh his firſt ſort, and *Lobel* calleth *Anchuſa lutea*. The ſecond *Columna* calleth *Anchuſa Echioides minor*. The third *Camerarius* in his Epitome calleth *Anchuſa altera minor*, and *Bauhinus Anchuſa minor Patavina*, and yet he diſtinguiſheth it from the *Anchuſa minor Alcibiadion ſive Onochiles* of *Lobel*, and *Cluſius* making them to be two ſorts, *Lonicerus* calleth it *Bugloſſa rubra*. The fourth is called by *Lobel* and *Pena* in their *Adverſaria*, *Anchuſa lignoſior anguſtifolia*, and by *Cluſius*, *Anchuſa lignoſior*, *Bauhinus* calleth it in his *Pinax*, *Anchuſa anguſtifolia*, and ſaith it is the ſame he formerly in his *Phitopinax*, called *Lithoſpermum minus repens*, and in his *Matthiolus Lithoſpermum fruticoſum anguſtifolium*, and ſaith alſo that this is the ſame that *Lugdunenſis* ſetteth forth, under the title of *Tragoriganum Monſpelienſe Dalechampij*. The two laſt are remembred by *Alpinus* in his Hiſtory of ſtrange Plants, under the ſame titles they are here expreſſed. The *Italians* call it *Anchuſa*, the *Spaniards Soagem*, and as *Cluſius* ſaith *Argamulo*, the *French Orchanette*, the *Germanes Oxenzunge*, the *Dutch Ghile Anchuſa*, and take it for a wilde Bugloſſe, we in *Engliſh* after the *French* word, *Alkanet*.

The Vertues.

Dioſcorides ſaith that his firſt kinde (which as I ſuppoſe, is that I have deſcribed in this and my former Booke, with a purpliſh flower) doth helpe old ulcers, and thoſe that are burnt with fire, being made into a ſalve with waxe and oyle, and uſed with barly flower, it cureth all hot inflammations, and even that which is called Saint *Anthonies* fire, uſed with vinegar, it helpeth the morphew, lepry, and the like; the ſame alſo applyed to the lower parts, draweth forth the dead childe; the decoction thereof made in water, for thoſe that are aguiſh, or elſe in wine, is profitable for thoſe that are troubled with the yellow Iaundiſe, the ſpleene or gravell, and the ſtone in the kidneys; the Apothecaries that uſed to make ointments ſaith he, uſed it to thicken their ointments; which *Pliny* altereth (as he doth in ſome other things, relating the text of *Dioſcorides*) and ſaith it is uſed to

colour oyntments, and for that purpoſe they take *Cinnabaris* and *Anchuſa*. To the ſecond kinde (which we generally take to be that with the yellow flower, and is the firſt here deſcribed) *Dioſcorides* giveth theſe properties; that whether it be eaten or drunke, or but bound to the wound, it helpeth all ſuch as are bitten by Serpents, eſpecially by the viper (or adder) and that if any that hath eaten hereof ſhall but ſpit it into the mouth of any Serpent, it will preſently kill it, the leaves (but much more the roote) being drunke in wine ſtayeth the fluxe of the belly. *Pliny* addeth hereunto ſomewhat more; the chiefeſt ſtrength hereof ſaith he is in harveſt time, a draught of wine wherein ſome of the dryed leaves and rootes have beene boyled, and given to thoſe that are troubled with the falling downe of the mother doth helpe them; it killeth wormes, being taken with Hyſſope. it is good alſo taken in wine for the paines of the backe and reines, as alſo for the liver. *Galen* doth more acurately and diſtinctly ſet them forth in this manner. *Onoclea* ſaith he hath a roote aſtringent and ſomewhat bitter, and thereby fit both to condenſate the thinne humours in the body, and ſomewhat to extenuate thoſe that are thicke, and as well to clenſe the chollericke, as to waſh the ſalt humours therein; for it is ſaid before, that a harſh taſted quality joyned with a bitter, can performe thoſe properties; in the like manner it is profitable for the yellow jaundiſe, for thoſe that are ſpleneticke, and for thoſe that have paines in the backe and loines, by reaſon of the ſtone in the kidneyes. It is alſo cooling and applyed with Barly flower, helpeth inflammations and Saint *Anthonies* fire: it clenſeth alſo either inwardly taken, or outwardly uſed, and therefore with vinegar helpeth morphews, lepries and the like, but theſe properties are chiefly in the rootes, yet the leaves although they be weaker then the roote, are not without the qualities of drying and binding, and therefore they being taken in wine, are good for all fluxes and laskes, but that which is called *Onochiles* or *Alcibiadion* is more phyſicall, for in taſte it hath a greater acrimony, and ſpeedily helpeth thoſe that are bitten by a viper, whether they eate it, or apply it as a ſalve to the wound, or but hang it or tye it to the wound, but the little *Anchuſa*, which ſcarſe hath a name, is like unto the *Alcibiadion*, being more bitter, and therefore more fit to give remedy, and is good to kill the broad wormes in the body, being given to drinke with Hyſſope and Creſſes, thus ſaith *Galen*. It is of late daies given to thoſe that are bruiſed by ſome fall, or by beatings, or any other caſualties, as alſo to drive out the ſmall poxe, meaſles, or the like, to be drunke in hot drinke. Some have ſaid that it will colour waters, gellies, and the like; but *Pliny* ſaith it will not diſſolve in water, but in oyle, and ſo we have it true by experience, yet the colour holdeth not long, being boyled in oyle, butter, or other fat thing; and therefore the painting that was made therewith by the *French* Ladies, ſerved onely for a ſmall while, except they take it while it is freſh; but the oyntment that is made with a pint of good ſallet oyle, wherein two ounces of the rootes of Alkanet, and twenty earthwormes hath beene boyled, and afterwards ſtrayned forth and kept in a pot, is a ſingular good ſalve to uſe for any freſh wounds, made either croſſe the fleſh or deepe thruſts thereinto, or into the body, as alſo where nerves and ſinewes are, to conſolidate and knit them againe; ſome of the roote put into *Petroleum*, or oyle of *Peter*, and being let ſtand till any one needeth, it is a ſingular good remedy to heale any freſh cut or thruſt: workemen of all ſorts, that uſe ſharpe and pointed tooles, ought to have it familiar among them, to uſe upon all occaſions of harme.

CHAP. XXI.

Lycopſis. Wall Bugloſſe.

BEcauſe this herbe is ſo like unto the *Anchuſa*, that as *Dioſcorides* ſaith, it was called of divers *Anchuſa*, and *Galen* in his time accounted it as a kinde thereof, as alſo that is like unto *Echium*, and other ſorts of wilde Bugloſſe, whereof *Anchuſa* is alſo accounted a ſpecies; I thinke it fit to joyne it next unto them, whoſe deſcription is as followeth; it ſpreadeth upon the ground, with many long and narrow rough or rugged darke greene hairy leaves, ſomewhat like unto the *Echium* or wilde Bugloſſe, which doe abide in that manner, ſome yeares, without ſending forth any ſtalke or flowers at all, (which divers having marked, have thought it never did beare flower or ſeede,) but if it or any other plant ſhould doe ſo, how could any man thinke it could come there, or any where elſe, where they are found; and therefore I am verily perſwaded, there is no herbe or plant growing upon the ground, but hath a kinde of ſeede, whereby it is encreaſed, in all the places where they are naturall; I doe neither except the Fearne, Maidenhaire, Miltwaſt, Harts tongue, Coltsfoote, Butter burre, or any other whatſoever, although I know this my opinion, doth not onely contradict divers other more learned mens obſervations, or rather other mens conceites now adaies (but it hath beene ſufficiently I thinke ſaid before in the Chapter of *Cynogloſſum*, that as that, ſo this notwithſtanding, that it doth not beare a ſtalke for flowers or ſeede ſome yeares, yet it is found to beare it in others; becauſe divers plants of each kinde, have beene found, as well with ſtalkes and flowers, as voide and without) and when it beareth a ſtalke which riſeth two foote high, it carryeth many ſuch like leaves thereon as grow below, but ſet one diſtant from another, without order and ſmaller up to the toppe, where the flowers ſtand upon the ſeverall branches, that it hath ſpread, as alſo comming forth at the joynts with the leaves, like unto the hollow flowers of *Echium* or Wild Bugloſſe, with uneven and gaping dented brimmes or edges, of a pale purple colour, with a long ſtile or pointell in the middle, growing out of the flower above the length thereof; after which followeth ſeede like unto Bugloſſe, but not altogether ſo great or blacke, the roote is ſomewhat wooddy, long, and not much greater then a finger with ſome fibres thereat, of a browniſh red on the outſide, little or nothing colouring the fingers, as the *Anchuſa's* doe.

2. *Lycopſis Anglica.* The *Engliſh* Wall Bugloſſe.

This *Lycopſis* differeth very little in leaves, ſtalkes, or flowers from the former, the onely difference conſiſteth in that the flowers doe all grow at the toppes of the branches, and are of a deeper purple colour, with divers threds ſhooting out of them, the roote is a little reddiſh like the other, and giveth as little colour.

3. *Lycopſis Ægiptiaca.* *Egyptian* Wall Bugloſſe.

The roote hereof is red, the ſtalke ſtraight, and two cubits high, with many rough and hard leaves like unto Bramble leaves, but long narrow and pointed, ſpread upon the grouud, and diſperſed upon the ſtalkes, but not

in that manner the rough wilde *Cynogloſſum* doth, the ſtalke is branched from the middle to the toppe thereof into a number of ſlender twigges, bare or naked of leaves for a good diſtance, and the flowers at the ends of them, which are ſmall, and of a purple colour, made of ſixe leaves like a ſtarre.

The Place.

The firſt groweth not farre from the ſea-ſhore about *Frontignan* neare unto *Mompelier*, as *Pena* and *Lobel* ſay: the other *Lobel* obſerved in the Weſt country in the way from *Briſtow* and *Bath* to *London*: the laſt *Rauwolfius* ſaith hee found in a field where corne grew in *Egypt*.

The Time.

Theſe flower about *Iuly*, and ſometimes in *Auguſt*.

The Names.

It is called in Greeke λυκόψις *Lycopſis*, *ſic dicta ut aliqui volunt, quod caulis foliorum & florum impexa hirſuties pedem Lupinum imitat, vel ut alij, ob radicis fuſcum ex purpureo colorem a quo Lycopſis derivata fuit; id eſt, fuſcedo ſive obſcuritas quædam, qualis eſt diluculi ſummi & primæ lucis, quæ ortum ſolis præcedit, vel veſpertini crepuſculi, quæ vulgus in Gallia inter canem, & lupum vocat: ſed alij melius & verius ut opinor a florum hiante figura quæ lupi fauces apertos æmulatur*: ſome as you have heard did take the *Cynogloſſum vulgare* to be it, as *Ruellius* and *Fuſchius*; in which opinion *Matthiolus* ſaith, he himſelfe was formerly, but afterwards was diſſwaded becauſe the roote was not red, but in finding fault with them, hee himſelfe is reprehended by *Pena* and *Lobel*, I have given the ſame figure of *Lycopſis*, being not in flower for the *Cynogloſſum* of *Dioſcorides*: *Dodonæus* taketh the common Bugloſſe to be *Lycopſis*, and ſo doth *Lonicerus* alſo, and ſaith that the Bugloſſe in the warmer countries hath a redder roote; but herein ſurely he is much deceived; for the taſte and propertie, as *Galen* ſaith, is nothing ſo aſtringent in Bugloſſe, as is in *Lycopſis*, wherein it exceedeth *Anchuſa*, whereof he maketh it the fourth ſort; and beſides, *Dioſcorides* deſcribeth *Lycopſis purpuraſcente flore*, with a purpliſh flower, but ſo hath not Bugloſſe, but blew, although the buds be ſomewhat reddiſh, before they be full open. The firſt, as is ſaid, is *Matthiolus* his *Cynogloſſum*, whom *Lugdunenſis* doth follow and *Durantes* alſo. *Dodonæus*, as is before ſaid, maketh our knowne Bugloſſe to be the *Lycopſis* of *Dioſcorides*, and calleth this *Lycopſis Echij altera ſpecies*. *Lobel* and *Pena* in their *Adverſaria* calleth it *Lycopſis vel Lycopſis degener Anchuſa Æginetæ*. *Bauhinus* doth call it *Lycopſis* ſimply without more words, and he maketh his *Lycopſis altera Anglica*, to be it alſo, although *Lobel* ſheweth the difference: the laſt is ſet forth in the *Appendix* to *Lugdunenſis*, where hee ſheweth that *Rauwolfius*, who found it, did account it a kinde of *Cynogloſſum*, and called it *Lycopſis vera Dioſcoridis*.

Lycopſis Anglica. Engliſh Wall Bugloſſe.

The Vertues.

The roote of Wall Bugloſſe boyled in oyle, healeth greene wounds ſpeedily, and applied with Barly flower helpeth all inflammations, and St. *Anthonies* fire, and being anointed in convenient places, provoketh ſweate. *Galen* in his ſixt Booke of Simples ſaith, that *Lycopſis* is cold and drie, and more aſtringent than *Anchuſa*, eſpecially the roote, and therefore is very good againſt inflammations: it ſtaieth rheumes and fluxes, and the acceſſe of hot and ſharpe humours to old ſores, whereby they are hard to be cured.

CHAP. XXII.

Onoſma. Stone Bugloſſe.

THe forme and likeneſſe of this plant with the former, and both with *Anchuſa*, hath made me to joyne it next to them, although the vertues hereof be not anſwerable unto them: it hath many long and narrow ſmooth leaves lying upon the ground, not above a finger broad, but foure long, like unto thoſe of the leſſer Alkanet; this is ſaid by *Dioſcorides* to have a reddiſh roote, and to be without either ſtalke flower or ſeede, which thing he ſaith likewiſe of *Cynogloſſum* and *Lycopſis*, which both have beene knowne in divers plants, to beare both flowers and ſeede, and therefore it is as probable in this, as in them. *Matthiolus* onely ſaith, that ſuch a plant was brought unto him, with long leaves, and reddiſh rootes like thoſe of Madder, and had neither ſtalke nor flower, which he thereupon tooke to be the right *Onoſma*, not knowing whether it had or would beare.

The Place.

It groweth in rockie and ſtony places neare *Goritia*.

Onoſma. Stone Bugloſſe.

The Time.

It is greenē all the yeare, and his timē for flowring if it doth at all, is not expreſſed.

The Names.

It is called in Greeke Ὄνοσμα, and ſo likewiſe *Onoſma* in Latine, *Galen* ſaith it was called alſo in his time *Oſmas Phlomitis*, and *Ononis*; wee may call it in *Engliſh* for diſtinctions ſake Stone Bugloſſe, both for that it is like in forme and manner of growing unto ſome of the ſort sof wilde Bugloſſe, and that it chiefely deligheth in ſtony dry, and rockie grounds.

The Vertues.

This is ſharpe, hot, and bitter in taſte, differing in qualitie from the other ſorts before, which are rather cold and dry: the leaves hereof in powder taken in wine, or the decoction of them made in wine and given to women with child, will cauſe them quickly to miſcarry, and if the child be dead before the birth, it will cauſe it ſpeedily to be driven forth; it is alſo dangerous ſaith *Dioſcorides* for great bellied women to paſſe over it, for feare of cauſing them to miſcarry.

CHAP. XXIII.

Cerinthe. Honywort.

ALthough in former dayes there was but one kinde of *Cerinthe* knowne, or two at the moſt, yēt ſince in theſe our dayes, there have beene ſome other ſorts found out, and publiſhed by *Cluſius*, and ſome others alſo not untill now expreſſed by any; and although *Geſner* firſt, and *Bauhinus* following him, doe call it *Cynogloſſum montanum*, and thereupon joyneth it next thereunto, yet by comparing the flowers, I finde it therein moſt to reſemble the Comfryes, and therefore I have interpoſed it betweene them.

1. *Cerinthe major flore luteo & rubro.*

The greater yellow and red Honywort.

The greater party coloured Honywort, riſeth up with divers thicke, hairy ſtalkes, almoſt two foote high, whereon are ſet large long leaves, of a blewiſh greene colour, ſpotted with great white ſpots, round at the further ends, and ſo much compaſſing the ſtalkes at the lower end, that it ſeemeth to goe thorough them, ſet with ſome ſmall prickes or thornes thereon, and a little hairy withall: the ſtalkes are branched toward the toppes into other ſmaller ones, full of leaves but much ſmaller, whoſe ends doe turne inwards like the Turneſole heads; at every leafe whereof commeth forth a long hollow flower, like unto a Comfrey flower and as great, which in ſome are all yellow, with a reddiſh circle about the middle thereof; but in others from the middle forward is of a yellow colour, the other part next the ſtalke being of a purpliſh red colour, with ſome threds in the middle, taſting ſweete like Hony, wherewith Bees are much delighted, each of them ſtanding in a greene huske divided into five parts at the toppes, in which after they are paſt grow the ſeede, two for the moſt part ſet together, greater than Burrage ſeede, blackiſh, a little cornered and flat at the bottome, where it is joyned to the huske;

1. *Cerinthe major flore luteo & rubro.*
The greater yellow and red Honywort.

thē

3. 5. *Cerinthe major flore flavo vel purpureo.*
The greater yellow or purple Honywort.

4. 6. *Cerinthe minor flore flavo vel albo.*
The leſſer yellow or white Honywort.

the roote is ſomewhat great and thicke, ſpreading many fibres within the ground, but periſheth every yeare after ſeede time.

2. *Cerinthe minor flore luteo & rubro.* The leſſer red and yellow Honywort.

This leſſer Honywort, hath his branches both ſhorter and leaning downewards, not ſtanding upright, whereon grow long greene leaves, without any ſpots on them, and leſſer than the former: the tops of the branches are as full of leaves and flowers as the former, but turne not in the ſame manner: the ſtalkes that ſuſtaine the flowers, and ſo likewiſe the ſmall leaves at the foote of every ſtalke, are ſomewhat purpliſh, but the huske wherein the flower ſtandeth is greene, cut into five diviſions, the flower is long and hollow like the former, and almoſt as great, of a gold yellow colour, dented at the ends, and with a red or deepe crimſon circle about the middle of them: the ſeede that followeth is like the former, but a little leſſer: the roote is long and full of fibres, periſhing every yeare.

3. *Cerinthe major flavo flore.* The greater yellow Honywort.

This yellow Honywort riſeth up with a reaſonable great ſtalke, branched on all ſides from the bottome to the toppe, many of the lowermoſt lying upon the ground, and the other ſtanding more upright, whereon are ſet large and long blewiſh greene leaves, ſpotted as the former is, but not ſo large at the bottome, where they compaſſe the ſtalkes, yet having ſome prickles in the middle thereon as they have, and a little hoary about the brimmes or edges; the toppes of the branches doe bend downewards ſet with ſmall leaves and flowers at them as the former, and as great, but without any circle or bottome of purple, being wholly of a faire yellow colour, with ſuch like threds as the reſt have; the ſeede is like the former, and ſo is the roote alſo periſhing after ſeede time in the ſame manner.

4. *Cerinthe minor flavo flore.* The leſſer yellow Honywort.

This ſmaller Honywort hath a ſlenderer ſtalke than the former, neare two foote high, ſet with ſmaller, narrower yet ſpotted leaves thereon without order, one above another on both ſides of the ſtalkes, which ſpreadeth into many ſmall but longer branches, from the middle thereof thicke ſet with leaves and flowers, which are like the laſt, all yellow but ſmaller, and dented at the brimmes of them; after which come ſuch like ſeede as the laſt, but ſmaller: the roote hereof is likewiſe white and long, and that which grew in my garden, did not abide the firſt Winters blaſt, and moſt uſually periſhed at the firſt therewith, yet *Cluſius* ſaith that his leſſer yellow ſort, which he found wild in the fields of *Auſtria* and *Stiria*, did ſometimes abide greene in the Winter.

5. *Cerinthe major flore purpurante.* The purple Honywort.

The purple Honywort groweth very like the great yellow kinde, with low bending branches, and ſomewhat large blewiſh greene ſpotted leaves, like as the reſt have: the flowers ſtand in the ſame manner that the reſt doe, and as large, wholly of a darke purpliſh colour, on the ſuperficies whereof is a little whiteneſſe perceived: the ſeede that followeth is like the other, but greater than any of them, and two for the moſt part ſtanding together in

in a huskē, flat at the bottome, the roote periſheth every yeare, and muſt be new ſowen againe.

6. Cerinthe minor flore albo. White Honywort.

This ſmall Honywort hath divers weake and ſmall branches, leaning or rather lying downe upon the ground, ſet with ſuch like pale greene leaves, but leſſer than the former, whoſe white ſpots are not ſo eaſie or conſpicuous to be ſeene as in many of the other: the flowers are white long and hollow, like them but ſmaller, with a reddiſh circle about the middle of the flower, and ſtanding with greene leaves, and in greene huskes as the reſt, wherein after they are paſt, come very likeſeede, but not halfe ſo great as the laſt; the roote likewiſe is long, ſlender, and white, periſhing every yeare after it hath given ſeede.

The Place.

The firſt as *Cluſius* ſaith, groweth generally throughout *Bætica* of *Spaine* plentifully, and in ſome places of *Portingall* alſo: the ſecond is not knowne from what place it came, but was onely obſerved by *Cluſius*, in *John ab Hogheland* his garden: the third *Cluſius* ſaith he found in the Kingdome of *Valencia* in *Spaine*. *Geſner in hortis* ſaith it groweth *in Monte Palatino* at *Rome*, as alſo in *Germany*, betweene *Dreſda* and *Miſena*: and *Cluſius* ſaith he found it in divers fields of *Auſtria* and *Stiria*, where ſometimes it would out-live a Winter; and *Dodonæus* ſaith in *Bohemia* and divers parts of *Hungary*: the fift and ſixt grow in divers places of *Spaine*, from whence we had them, by *Guillaume Boel* his diligence in finding them out there.

The Time.

They doe all flower in *July* and *Auguſt*, yet ſometimes ſo late, that we doe not gather good ſeede of any of them but the red, if the yeare prove not warme enough, and wet withall to ripen them, or be not well watered if the Sommer be drie to bring them forward the ſooner.

The Names.

Theophraſtus among the ancient Greeke Writers, in his 6. Booke, and 7. Chapter maketh mention of *Cerinthe*, and calleth it Κηρίνθη, and *Pliny* and *Virgil* among the ancient Latines, make mention thereof likewiſe, and it is but thought alſo to be their *Cerinthe*: *Pliny* ſpeaketh thereof in his 21. Booke and 12. Chapter, and *Virgil* in *quarto Gorgicorum* in theſe words,

——Huc tu juſſos aſperge ſapores,
Trita Meliphylla & Cerinthe ignobile gramen.

and not *granum* as ſome reade it; whereby is underſtood that it is a baſe or vile weede or herbe, growing every where as graſſe, for ſo divers herbes are named graſſe. Many learned men in *Germany* and *France*, eſpecially about *Paris*, where they nurſe it in their gardens, have called it *Telephium maculoſum*, ſuppoſing it to be the *Telephium* of *Dioſcorides*. *Dodonæus* and *Cluſius* ſaith, that many tooke it to be the herbe *Maru* or *Almara* of *Avicen*, whereof in his 464 Chapter, he maketh five ſorts, and this to be the fourth; but *Cluſius* ſaith that he taketh *Avicen* to meane no other herbe but either our Borage or Bugloſſe; he ſaith alſo this may very well agree with the *Leucographis Plinij*, whereof hee maketh mention in his 27. Booke and 11. Chapter, becauſe the leaves are ſpotted white; ſome alſo hee ſaith tooke it to be *Memitha* of the *Arabians*, but *Cluſius* ſuppoſeth that to be *Glaucium Græcorum*: *Geſner*, as I ſaid before *in hortis Germaniæ*, ſaith it was called of ſome in his time *Cynogloſſus montana*; and *Bauhinus* thereupon calleth it *Cynogloſſum montanum*; but *Cluſius* referreth it rather to the kindes of Borage or Bugloſſe, whereof in temperature he ſaith it is neareſt. *Dalechampius* tooke *Calendula* to be *Cerinthe, a cereo ipſius flore ſic appellata*: but the moſt uſuall and common name, whereby it is generally called now a dayes is *Cerinthe*, and *Plinij* added, becauſe the moſt and beſt Herbariſts, doe thinke it comes neareſt unto his deſcription. The firſt is called *Cerinthe major* by *Lobel* and *Camerarius*, and by *Cluſius Cerinthe quorundam major verſicolore flore*, and *Bauhinus Cerinthe ſeu Cynogloſſum montanum majus*: the ſecond is *Cluſius* his fift kinde, whereof he maketh mention in his other *Appendix*, which is joyned to his Booke of *Exoticke* things; and *Bauhinus* calleth it *Cerinthe folio non maculato viridi*: the third *Cluſius* calleth *Cerinthe quorundam major flavo flore*, and *Bauhinus Cerinthe floreſflavo aſperior*: the fourth is called by *Cluſius Cerinthe quorundam minor flavo flore*; by *Lobel Camerarius* and *Tabermontanus Cerinthe minor*, by *Lugdunenſis Cerinthe Plinij*: the fift is the third *Cerinthe* of *Cluſius* in his hiſtory of plants, and called by *Bauhinus Cerinthe flore rubro purpuraſcente*: the laſt is not yet extant, or remembred by any Author, we being the firſt to whom it was brought out of *Spaine* by *Guillaume Boel* before remembred.

The Vertues.

They are all of a temperate qualitie betweene cold and hot, but rather inclining to cold, and ſomewhat aſtringent withall, it is held good to ſtay the bleedings at the mouth or noſe, to ſtay womens immoderate fluxes, and the fluxes or laskes of the belly, the herbe being boyled and given to drinke: the juice of the herbe with a little ſaffron diſſolved therein, is good for bleared and watering eyes, and is uſed in foule ulcers after they are clenſed, to helpe to incarnate them, eſpecially ſuch as are in the tender parts of the body: Some doe apply it as a remedie whereunto Borrage and Bugloſſe are good. *Pliny* and *Virgil* in the places before mentioned, did affirme that Bees are much delighted with the flowers being ſweete, and from them as much, or more then from any other flowers, doe gather both Hony and Waxe, and thereupon peradventure it is more likely, tooke the name of *Cerinthe*.

CHAP. XXIV.

Symphitum majus. Great Comfrey.

THere are many ſorts of *Symphitum* called *Conſolida* and *Solidago*, that is *major*, *minor* and *media*, a greater, a leſſer, and a middle one: as alſo another kinde called *Symphitum petræum*, whereof *Dioſcorides* maketh mention, and another called *Conſolida* or *Solidago Saraſenica*; which becauſe they are all ſeverall herbes, I ſhall ſpeake of them ſeverally in the Chapters following: for in this I entend only to ſet forth unto you the greater Comfrey, which is of divers ſorts, ſome ordinary by growing wild, by the fields and ditches ſides of our owne land, others nurſed up onely in gardens with us.

1. *Symphi-*

1. *Symphitum majus vulgare.*
Common great Comfrey.

3. *Symphitum tuberosum.*
Comfrey with knobbed rootes.

1. *Symphitum majus vulgare.* Common great Comfrey.

The common great Comfrey hath divers very large and hairy darke greene leaves lying on the ground, so hairy or prickly, that if they touch any tender part of the hand, face, or other part, it will cause it to itch: the stalke that riseth up from among them, being two or three foote high, hollow and cornered, is very hairy also, having many such like leaves as grow below, but lesser and lesser up to the toppe; at the joints of the stalkes it is divided into many branches, with some leaves thereon, and at the ends stand many flowers in order, one before or above another, which are somewhat long and hollow, like the finger of a glove, of a pale whitish colour, after which come small blacke seede: the rootes are great and long spreading great thicke branches under ground, blacke on the outside and whitish within, short or easie to breake, and full of a glutinous or clammy juyce, of little or no taste at all.

2. *Symphitum majus purpureo flore.* Great Comfrey with purple flowers.

This Comfrey differeth in no other thing from the former, but in this that it is somewhat lesser, and the flowers are of a pale purple colour.

3. *Symphitum tuberosum.* Comfrey with knobbed rootes.

The knobbed Comfrey riseth up with a hairy crested or cornered stalke, much lower than the former, with smaller leaves, and more thinnely set thereon, of the same forme and greeneneſſe, that thereby it may at the first sight, to any that hath well marked the former, be knowne to be a Comfrey; but especially when the toppe branches are in flower, which being set after the same manner, and of the same hollow fashion, but smaller, are of a more sad yellowish colour, whose seede following is like the former: the rootes branch out into thicke and short sprayes, more knobbed at the ends with divers fibres thereat, blacke on the outside and yellowish within, frought with such clammy or slimie juice, as is in the former, but not so glutinous, yet as tender or easie to be broken as it, or rather more easie: the stalke and leaves dye downe every yeare as they doe in the former: the roote abiding and increasing in the ground, and shooting forth new stalkes and leaves every Spring: some doe make a lesser sort hereof, which I never saw, nor can be well assured thereof. *Minor.*

4. *Symphitum angustifolium Apulum.* Narrow Comfrey of *Naples.*

This narrow leafed plant *Columna* maketh an Alkanet like an *Echium*, yet from the viscous or slimy binding and sodering juice in the roote, may (as hee saith himselfe) therefore be accounted rather a Comfrey, and so doe I among them with the description thus. The roote while it is young is reddish, but growing old is long and wooddy, greater than the smallnes of the plant might seeme to have with a blacke rugged barcke, in, which sendeth from it sundry heads of narrow long leaves round about it with a whitish hairinesse on them, from among some of which rise reddish stalkes of a foote or more high, with somewhat broader leaves up higher thereon, at the toppes whereof which turne themselves like to a Scorpions taile, grow many hollow long, yellow flowers, opening at the brimmes into five parts, all of them flowring one after another with a long pointell in the middle of them, after which come foure blackish browne smooth seeds in each huske.

The

The Place.

Both the former grow by ditches and waterſides, and in divers fields that are moiſt, for therein chiefly they delight to grow, the firſt generally through all the land, and the other but in ſome ſeverall places, the third in the Woods of *Germany*, *Auſtria*, and *Hungary*, but in gardens onely with us: the laſt in the ſtony places of the hils of *Æquicoli* in *Naples* on the Southſide.

The Time.

They flower in *Iune* and *Iuly*, and give their ſeede in *Auguſt*.

The Names.

It is called in Greeke σύμφυτον & σύμφιτον *ſymphytum* and *ſymphitum*, *a facultate glutinandi ſic dictum*, *unde Conſolida Latinis*: it is alſo called as *Dioſcorides* ſaith πικτὸς, or πικτὸν, *pectos* or *pecton*. *Pliny* ſaith it was called *Alus* and *Alum*, and is alſo of ſome called *Solidago*, and of *Scribonius Largus Inula ruſtica*, of ſome as *Dodonæus* ſaith, *Oſteocollon*; and *Unctuoſa* from the *Germane* word *Schmerwurtz*: but the moſt uſuall name is by all authors now adaies, either *Symphitum* or *Conſolida major*; that with purple flowers is called *mas*, and the white *fœmina*. The ſecond is ſo called by moſt, as is in the title The laſt ſort I have tranſpoſed hither, with a new title, as being fitteſt for it in my judgement, although both *Columna* and *Bauhinus* make it an *Anchuſa*, for ſome reaſons ſet downe in the deſcription, *Columna* calleth it *Anchuſa echioides lutea Cerinthe flore montana*, and *Bauhinus Cerinthe lutea minor*. The *Italians* call it *Conſolida maggiore*, the *Spaniards Suelda*, and *Conſuelda majore*, the *French Conſyre*, *Grande Conſolide*, and *Oreille d' Aſue*, the *Germanes Groſſwallwurtz*, *Schwartwurtz*, *Schmerwurtz Schantwurtz*, and *Beinwellen*, the *Dutch Waelwortole*, in *Engliſh* Comfrey.

The Vertues.

The great Comfrey is as ſome ſay, cold in a temperate degree, and others ſay hot, which is not held true, but drying and binding in a greater meaſure, for it helpeth thoſe that ſpit blood, or that bleede at the mouth, or that make a bloody urine: as alſo for all inward hurts, bruiſes and wounds, and helpeth the ulcers of the lungs, cauſing the fleagme that oppreſſeth them, to be eaſily ſpit forth, the roote being boyled in water or wine; the ſame alſo drunke, ſtayeth the defluxions of rheume from the head upon the Lungs, the fluxes of blood or humours, by the belly, womens immoderate courſes, as well the reds as the whites, and the *gonorrhœa* or the running of the raines, happening by what cauſe ſoever: A ſyrupe made thereof is very effectuall for all thoſe inward griefes and hurts; and the diſtilled water for the ſame purpoſe alſo, and for outward wounds or ſores in the fleſhy or ſinewy parts of the body whereſoever, as alſo to take away the fits of agues, and to alay the ſharpeneſſe of humours: a decoction of the leaves hereof is availeable to all the purpoſes, although not ſo effectuall as of the rootes: *Camerarius* ſaith, that two ounces of the juice drunke, doth much good in the Lethargy and dead ſleepe; the rootes being outwardly applyed, helpeth freſh wounds or cuts immediately; being bruiſed and laid thereto, by glueing together their lips, and is eſpeciall good for ruptures and broken bones; yea it is ſaid to be ſo powerfull to conſolidate or knit together, whatſoever needeth knitting, that if they be boyled with diſſevered peeces of fleſh in a pot, it will joyne them together againe; it is good to be applyed to womens breaſts, that grow ſore by the aboundance of milke comming into them: as alſo to repreſſe the overmuch bleeding of the hemorrhoids, to coole the inflammation of the parts thereabouts, and to give eaſe of paines: the rootes of Comfrey taken freſh, beaten ſmall, ſpread upon leather, and laid upon any place troubled with the gout, doe preſently give eaſe of the paines; and applyed in the ſame manner, giveth eaſe to pained joynts, and profiteth very much for running and moiſt ulcers, gangrenes, mortifications, and the like, often experimented and found helpefull.

CHAP. XXV.

Bugula ſive Conſolida media. Bugle or the middle Conſound.

THis browne Bugle is ſo like unto the *Prunella* or Selfe heale, that divers have made them but *ſpecies* to one *genus*, and ſo have confounded them together, and yet they have ſeemed to diſtinguiſh them, calling this *Conſolida media*, and the other *Conſolida minor*: yet there are other herbes that they ſo call alſo, which ſhall likewiſe be entreated of in the Chapters following; but I finding them to differ notably one from another, have diſpoſed of them ſeverally; intreating of the greater in this Chapter, and of the leſſer in the next.

1. *Bugula vulgaris flore cæruleo.* Ordinary blew flowred Bugle.

This Bugle hath larger leaves then thoſe of the *Prunella* or Selfe heale, but elſe of the ſame faſhion, or rather a little longer, in ſome greene on the upperſide and in others more browniſh, dented about the edges, ſomewhat hairy as the ſquare ſtalke is alſo, which riſeth up to be halfe a yeard high ſometime, ſet with ſuch leaves thereon by cuples; from the middle almoſt whereof upwards, ſtand the flowers together, with many ſmaller and browner leaves then the reſt on the ſtalke below, ſet at diſtances, and the ſtalke bare betweene them, among which flowers are alſo ſmall ones, as thoſe of Selfe heale, and of a blewiſh and ſometime of an aſh-colour, faſhioned like the flowers of Alehoofe, or Ground Ivy, after which come ſmall round blackiſh ſeede: the roote is compoſed of many ſtrings, and ſpreadeth upon the ground into divers parts round about. Of this kinde there is another whoſe leaves are longer then theſe, and deeper dented in about the edges.

Alia longioribus foliis

2. *Bugula flore albo.* Bugle with a white flower.

The white flowred Bugle differeth not in forme or greatneſſe from the former, ſaving that the leaves and ſtalkes thereof are alwaies greene and never browne like the other, and that the flowers are very white.

3. *Bugula flore carneo.* Bugle with bluſh coloured flowers.

This other Bugle differeth little alſo from the other before declared, but that it is a more tender plant, ſoft and ſmooth in handling, not riſing full ſo high as the former, and the flowers thereof are of a pale red or bluſh colour, which maketh the greateſt difference.

4. *Bugula*

4. *Bugula Alpina cærulea.* Blew mountaine Bugle.

The mountaine Bugle is not unlike the other, having longer and thicker leaves, especially at the bottomes of them, seeming for the smallnesse to be footestalkes, dented also about the edges, and somewhat hard or hairy, thinnely set by couples upon the square hairy stalkes, a foote high or more, at the toppes whereof the flowers stand in spikes, neerer set together then the former, and of a blew colour, fashioned like unto the rest; the roote is long, with divers fibres thereat.

1. *Bugula vulgaris.*
Ordinary Bugle.

5. *Bugula flore luteo.* Bugle with yellow flowers.

This yellow Bugle is smaller then any of the former by much, having rounder leaves upon the stalkes, and dented about the edges like unto them: the flower is yellowish, standing in the same manner that the rest doe.

6. *Bugula odorata Lusitanica.*
Sweete *Portingall* Bugle.

This kinde of Bugle riseth up with three or foure round and hairy stalkes about a foote high, at the joynts whereof grow leaves by couples, which are long hairy, and divided or torne on both sides into two or three gashes, each bowing backe a little, the largest leaves are lowest, and smaller still up to the toppes, where among the great spikie heads of flowers they are very small: the flowers are of a violet purple colour, formed hollow with lips as it were hanging downe, somewhat like the former Bugles, standing in cuppes, wherein afterwards grow white seede, which by sowing it selfe doth often rise againe, for it is but annuall, the roote is composed of many blacke fibres: all the whole plant hath a very pleasant sent.

The Place.

The first and second grow in woods and wet copses, and fields generally throughout *England* in many places, but the second is harder to be met withall. The third groweth in *Austria* and some other places of *Germany* as *Clusius* saith. The fourth upon Mount *Baldus*. The fifth is said to grow with us, and the last in *Portugall*.

The Time.

They all flower from *May* untill *July*, and in the meane time they perfect their seede, the roote and leaves next thereunto upon the ground, abiding all the Winter, untill the next Spring.

The Names.

It hath no Greeke name or author, that we are certaine of, but is called in Latine in these times *Consolida media*, and *Solidago media* (but there are many herbes that are called *Consolida* and *Solidago*, from their vertues as you shall finde them remembred in their severall Chapters) and *Buglum* or *Bugla*, as *Ruellius* saith the *French* were wont to call it, and more usually now a daies *Bugula*; but some as I said before confounded this with *Prunella*, making them all one: some also tooke this to be *Symphitum petræum* of *Dioscorides*, to which it answereth in nothing to his description, as you shall heare hereafter in the next Chapter, *Matthiolus* calleth it *Laurentina* or *Herba Laurentina*. Some would have it to be *Chamæcissos spicata Plinij. lib. 24. c. 15.* and others to be his *Anonymos. lib. 27. c. 4.* The first is called by *Tragus Prunella cærulea prima, vel major*, and as he saith is the *Prunella Argentinensis*, by *Thalius Consolida media major*, by *Dodonæus* and *Clusius Bugula*, by *Lobel* and *Pena Bugula* and *Prunella quibusdam*, by *Anguillara Arthretica Pandectarij*; by most writers *Consolida media pratensis cærulea*. The third is mentioned by *Clusius* with the name *Bugula carnei coloris flore*, by *Thalius Consolida media minor*, by *Tragus Prunella purpurea vel quarta* as *Bauhinus* thinketh, who calleth it himselfe *Consolida media pratensis purpurea*. The fourth *Bauhinus* describeth in his *Matthiolus* and *Prodromus*. The fifth is remembred onely by *Bauhinus* in his *Prodromus*, that he had it out of *England*. The last is mentioned by *Iacobus Cornutus*, among his *Canada* Plants. By the *Italians* it is called *Consolida mezana*, and of them of *Siena* as *Matthiolus* saith, *Morandola*, by the *French Bugle*, by the *Germanes Gunzel*, and *Gulden Gunzel*, by the *Dutch Sevegroen*, in *English* Bugle or Browne Bugle, and Middle Cumfrey or Consound.

The Vertues.

Bugle is temperate in heate, but drying moderately, and is somewhat astringent. It is of excellent use for those that have caught any fall, or are inwardly bruised, for it dissolveth the congealed blood, and disperseth it by taking the decoction of the leaves and flowers made in wine; the same is no lesse effectuall for any inward, wounds, thrusts or stabbes into the body or bowels, and is an especall helpe in all wound drinkes, as also for those that are Liver growne as they call it, whose inward griefes and paines arise from the obstructions of the Liver, and gall, and strengthening the parts afterwards; it is wonderfull in curing all manner of ulcers and sores, whether they be new and fresh, or old and inveterate, yea gangrenes and fistulaes also, either the leaves bruised and applyed, or their juice used to wash and bathe the places; and the same made into a lotion with some hony of roses and allome cureth all sores of the mouth or gums, be they never so foule or of long continuance, it worketh no lesse powerfully and effectually, for such ulcers and sores as happen in the secret parts of men or women: it helpeth those also that have broken any bone of their body, or have any dislocation of a joynt, both used inwardly, and applyed outwardly; an ointment made with the leaves of Bugle, Scabious, and Sanicle, bruised and boyled

3. *Bugula flore carneo.*
Bugle with blush coloured flowers.

6. *Bugula odorata Lusitanica.*
Sweete *Portingall* Bugle.

led in *Axungia* untill the herbes be dry, and then strained forth and kept in a pot, for such occasions as shall requir̄e it, is found so singular good for all sorts of hurts in the body, or any part thereof, that I would not wish any good Gentlewoman in the land, that would do good either to her owne family, or other her poore neighbors, that want helpe and meanes to procure it, to be without this ointment alwayes at hand by them, it hath done and would doe so much good, for beyond the Sea in *France* and *Germany*, it is a common proverbe amongst them, that they neede neither Phisition to cure their inward diseases, nor Chirurgion to helpe them of any wound or sore that have this Bugle (or the *Prunella* Selfeheale, for with them they are accounted but one herbe, as I said before) and Sanicle at hand by them to use.

CHAP. XXVI.

Prunella sive Consolida minor. Selfeheal̄e.

THer̄e be divers sorts of this Selfeheale, some differing in forme, others in colour onely, as you have them here set forth unto you.

1. *Prunella vulgaris.* The common Selfeheale.

The common Selfeheale is a small low creeping herbe, having many small and somewhat round yet pointed leaves, somewhat like the leaves of wild Mints, of a darke greene colour, without any dents on the edges at all, or very seldome, from among which arise divers square hairy stalkes, scarse a foote high which spread sometimes into branches, with divers such small leaves set theron, up to the toppes, where stand browne spiked heads, of many small browni sh leaves like scales and flowers set together almost like the head of *Stœchas* or *Cassidony*, which flowers are gaping and of a blewish purple, or more pale blew colour, in some places sweete, but not so in others: the roote consisteth of many strings or fibres downewards, and spreadeth stringes also whereby it encreaseth, the small stalkes with the leaves creeping upon the ground, shoote forth fibres, taking hold of the ground, whereby it is made a great tuft in a small time.

2. *Prunella vulgaris flore albo.* Selfeheale with a white flower.

This Selfeheale differeth very little from the former, in any thing but in the flower, which in this is pure white, and the small scales or leaves greene and not browne, saving that it doth not encrease or spread so much.

3. *Prunella magno flore purpureo.* Selfeheale with a great purple flower.

The greater flowred Selfeheale, hath a square solft hairy stalke, rising somewhat higher then the ordinary, with two leaves, and sometimes more at every joynt thereof, up to the toppe, which are somewhat greater

and

and longer than thoſe of the former: the heads of flowers at the tops are much greater than in the former, but made after the ſame faſhion, with ſmall browne leaves among the flowers, but greater and more open and diſplayed, which in ſome are of a blewiſh purple colour, in other more pale, or almoſt blew or pale blew: after which come foure ſmall ſeedes ſet together in a huske: the roote is blacke with white fibres thereat ſhooting forth and encreaſing new heads of leaves every yeare.

4. *Prunella magna flore albo.*

Selfeheale with a great white flower.

This ſelfeheale likewiſe differeth from the laſt onely in heade and flowers, for the ſmall leaves are greene, and the flowers white, as in the ordinary ſort before.

5. *Prunella Laciniato folio.*

Selfeheale with jagged leaves.

The ſtalkes of this Selfeheale are likewiſe ſquare and hairy as the leaves ſet thereon by couples at the joynts, the loweſt whereof are long and whole without any cut or jagge in them, all the reſt being longer and narrower, are cut in or jagged on the ſides, and the higer leaves more divided or cut: the heads are like thoſe of the common ſort, and of the ſame forme and bigneſſe, but varying in colour as both the former ſorts doe; for ſome plants are found with purpliſh flowers, others more delaied like blew, ſome betweene blew and white, like an aſh colour; others altogether white: the roote bereof is like the other, and encreaſeth by the ſhooting ſtrings, that put forth freſh leaves every yeare.

The Place.

The two firſt are found in woods and fieldes every where, yet the ſecond much more ſeldome than the former: the third and fourth, and ſo likewiſe the laſt, on divers hills and parts of *Germany* and *France*.

The Time.

The two firſt ſorts flower in *May*, and ſometimes in *Aprill*, the other ſort, ſomewhat later, as for the moſt part all mountaine herbes doe.

5. *Prunella Laciniato folio ſive Symphytum petræum Lobellij.*
Selfe heale with jagged leaves.

The Names.

This is generally called *Prunella* (for it was not knowue to the ancient Greeke or Latine Writers, that can yet be found) and *Brunella* from the *Germans*, who called it *Brunnellen*, becauſe it cureth that diſeaſe which they call *die Bruen*, common to ſouldiers in campe, but eſpecially in gariſon, which is an inflammation of the mouth, throate, and tongue, with blackneſſe therein, accompanied for the moſt part with a ſtrong burning feaver, and diſtraction of the ſenſes: it is alſo called *Conſolida minor*, and *Solidago minor*, and of *Camerarius Conſolida minima*. *Lobel* and ſome others alſo with him, tooke it eſpecially that with jagged leaves to be *Symphitum petræum* of *Dioſcorides* which that it cannot be, you ſhall heare the deſcription thereof as *Dioſcorides* giveth it: (that is *Symphitum petræum*) groweth ſaith he in rockie and ſtony places, with ſlender ſmall branches like *Origanum*, and with the heads and leaves of Time; it is all woody, ſwelling ſweete and pleaſant in taſte, yet drawing water into the mouth: and cauſing one to ſpit it out: the roote is ſomewhat reddiſh or browne, of the length of a finger; yet ſome coppies have, it hath branches like *Origanum* and ſmall leaves and heades like Time: this is *Dioſcorides* his text: but this herbe Selfeheale, hath no wooddy ſtalkes, nor reddiſh rootes, nor ſmelleth ſweete except in ſome places, nor doth it ſo ſtrongly conſolidate or knit fleſh together, as the great Comfrey doth; which is one of the properties *Dioſcorides* appropriateth unto *Symphytum petræum*. *Lobel* therefore firſt imagined that the *Coris Monſpelienſium* ſhould be it; *Bauhinus* alſo after him ſaith he did, but afterwards he learned that *Matthiolus* his *Symphitum petræum*, was much differing, his figure being of *Coris lutea*. The firſt and ſo the reſt are called *Brunella*, by *Brunfelſius*, *Dodonæus* and *Lobel*, by *Tragus Prunella vulgaris*, and ſo by all Authors, only as I ſaid before, *Lobel* in his *Adverſaria* calleth this laſt, *Symphytum petræum* and *Bauhinus Prunella Laciniato folio*.

The Vertues.

The Selfe heale being ſo like the Bugle as I ſaid in outward forme, is no leſſe like it in the qualitie and vertues being by the bitterneſſe taken to be hot and drie, and yet temperate in both degrees, and by ſome thought to be rather more cold, in regard it is ſo powerfull to helpe ſuch an hot ſickneſſe as the *Germane* diſeaſe, called *die Bruen*, which as hath bin in ſome part ſaid before, commeth with inflammation and ſwelling both in the mouth and throate, the tongue rough and rugged or blacke, and a fierce hot continuall ague thereon, which is remedied chiefely by drinking the decoction of this herbe continually, and waſhing the mouth often alſo therewith, having ſome vinegar added unto it; but bloud letting muſt be uſed in the cure, and that under the tongue, without which it will not, or very hardly be effected: this herbe ſerveth for all the purpoſes whereunto Bugle is applied, and with as good ſucceſſe both inwardly and outwardly: for inward wounds and ulcers whereſoever within the body: for bruiſes and falls, and other ſuch griefes, for if it be accompanied with Bugle, Sanicle, and other the like wound herbes it will be the more effectuall and to waſh or inject into ulcers, in the parts outwardly, for where there is cauſe to repreſſe the heate and ſharpeneſſe of humours, flowing to any ſore, ulcer, inflammation, ſwelling or the like; or to ſtay the fluxe of bloud in any wound or any part, this is uſed with good ſucceſſe, as alſo to cleanſe the foulneſſe of all ſores, and to cauſe them the more ſpeedily to be healed: it is an eſpeciall remedy

medy for all greene wounds to ſoder the lippes of them, and to keepe the place from any further inconvenience: the juyce hereof uſed with oyle of Roſes, to annoint the temples and forehead, is very effectuall to remove the head-ach, and the ſame juice mixed with a little Hony of Roſes, clenſeth and healeth all ulcers and ſores in the mouth and throate, and thoſe alſo in the ſecret parts: the ſame ointment that is ſet downe in the former Chapter is made as often with this herbe inſtead of Bugle; if it be not at hand, or if it be, yet they are oftentimes both put together, to ſerve to helpe broken bones, or joints out of place: the Proverbe of the *Germans*, *French*, and others, whereof is made mention in the former, is no leſſe verified, as I there ſaid then of this, that he needeth neither Phyſition or Chirurgion, that hath Selfeheale and Sanicle by him to helpe himſelfe.

CHAP. XXVII.

Bellis. The Daiſie.

THere be many ſorts of Daiſies, ſome growing wild both greater and ſmaller, and others in gardens chiefely, whereof I have in my former Booke given you the hint of divers, but many more is to be ſpoken of here, that is not there ſet downe, which are fitter for this than that place; and I am the more willing and thinke it fitter to joyne their Chapter next unto the laſt, becauſe ſome of them are called *Conſolida*, which I would ſet altogether.

1. *Bellis major vulgaris ſive ſylveſtris.* The great white wild Daiſie.

The great white Daiſie hath many long narrow and round pointed leaves next the ground, cut in on both ſides, making it ſeeme almoſt like the diviſions of ſome ſorts of Oaken leaves, the ſtalkes grow to be ſomewhat high, with divers leaves thereon, but ſmaller and leſſer divided than the lower, at the toppes whereof grow large flowers each upon ſeverall footeſtalkes, conſiſting of many white and narrow leaves as a pale or border, and the yellow thrummes in the middle, of no ſent at all, whoſe ſeede which is ſomewhat long is blowen away with the winde: the roote is a buſh of white ſtringes, which abide many Winters with the leaves, ſhouting forth every Spring anew. Of this kinde there is one that beareth double flowers differing from the former in nothing elſe, which is ſet forth in my former Booke. *Flore pleno.*

2. *Bellis montana major folio acuto.* The mountaine great Daiſie with ſharpe pointed leaves.

This Daiſie groweth lower than the former, and hath much narrower leaves, and ſhorter alſo, not deepely dented, nor ſharpe about the edges, but ending in an exquiſite point; the ſtalkes beare but one flower apeece, ſomewhat leſſe than the former, but elſe in all things alike.

1. *Bellis major vulgaris ſive ſylveſtris.*
The great white wilde Daiſie.

4. *Bellis major ramoſa umbellifera Americana.*
The great ſtrange white Daiſie.

3. *Bellis*

3. *Bellis Alpina major rigido folio.* The greater mountaine Daiſie with ſharpe edged leaves.

The leaves of this Daiſie are longer and narrower then the firſt ſort, whoſe dented edges are very ſharpe, and the leaves harder in handling, the endes in ſome are pointed, in others ſomewhat rounder: the toppes of the ſtalkes are furniſhed with ſingle flowers like the firſt, but larger then it: the ſeede is ſmall and long like it, and the rootes are blackiſh with ſtrings or fibres thereat, being ſomewhat hard and wooddy.

4. *Bellis major ramoſa umbellifera Americana.* The great ſtrange white Daiſie.

The ſtalke of this great Daiſie is higher and greater then of the firſt great ſort, the leaves alſo are larger, and broadeſt towards the ends, but longer and ſmaller at the bottomes, dented likewiſe about the edges, ſhooting forth ſundry branches, and all of them bearing many white flowers at their toppes, as it were in an umbell, yet not ſo great, nor the white leaves ſo large as it, but ſmaller, and more in number, with a greeniſh yellow thrumme in the middle, and ſome a little larger then others, the ſeede is ſmaller then the other, and the roote full of fibres.

5. *Bellis Alpina minor rigido folio.*

The ſmaller great Mountaine Daiſie with rigid leaves.

This mountaine Daiſie is very like unto the laſt but that it is leſſe, growing ſcarſe a foote high, with hard or harſh narrow or ſhort leaves, deepely and ſharpely dented at the edges: the ſtalkes have each of them one large flower, made like the reſt, whoſe border of white leaves, have ſometimes yellow, and ſometimes purpliſh yellow thrums in the middle.

6. *Bellis maritima foliis Agerati.*

The ſmall Sea Daiſie with *Maudeline* leaves.

This ſmall Sea Daiſie, riſeth with a ſmall downy ſtalke, not above halfe a foote high, divided into two or three very ſmall and long branches, at the bottome whereof grow a few very ſmall leaves, dented about the edges, very like unto the leaves of *Maudeline*, the reſt of the ſtalkes and branches, being bare or naked of leaves unto the toppes, every one whereof beare one ſmall flower, having above twenty ſmall white leaves, compaſſing a greeniſh head in the middle: the roote is ſmall and white.

7. *Bellis major ſpinoſa flore luteo nudo.*

The greater yellow Daiſie with prickly leaves.

This prickely leafed Daiſie ſpringeth up with divers heads, of many ſmall greene leaves, dented about the edges, and every dent ſharpe at the point, which ſhooting up into ſtalkes, with the like, but leſſer leaves on them, become hard and wooddy up to the toppes, ſometimes branched, otherwhiles not, but carrying on their toppes divers ſmall round flowers, on ſeverall ſmall footeſtalkes, which have no border of leaves, either white or yellow to compaſſe them, but are like the naked Camomill, or Fetherfew, and ſomewhat leſſer, being a yellow round knop, ſomewhat hollow in the middle; after the flower is paſt, there ſtand in their places ſmall heads with ſeede, each whereof is ſmall long and whitiſh, which muſt ſoone be gathered when it is ripe, or elſe it quickely falleth, or is blowne away with the winde, the roote is a great tuft or buſh of long blackiſh ſtrings, or long fibres; the taſte hereof is bitter and unpleaſant, and the ſmell ſomewhat ſtrong.

7. *Bellis majo ſpinoſa flore luteo nudo.*
The greater yellow Daiſie with prickly leaves.

8. *Globularia Monſpelienſium Bellis cærulea.*
Blew Daiſies.

8. *Globularia Monſpelienſium ſive Bellis cærulea.*

Blew Daiſies.

The blew Daiſie hath many narrower ſhorter and blacker greene leaves then the common field or garden ſmall Daiſie lying on the ground: the ſtalke riſeth to be halfe a foote high or more, ſet with ſome ſuch ſmall leaves, and at the toppe a ſmall round head, compoſed of many blew flowers, ſomewhat like unto the head of a ſmall Scabious, and ſometimes with white flowers: the roote is hard and ſtringy, the whole plant is bitter in taſte.

9. *Bellis cærulea ſpinoſa.*

The blew Daiſie with prickely leaves.

This Daiſie is wholly like the former blew Daiſie, but that the leaves that grow below upon the ground, as well as thoſe upon the ſmall ſtalkes, being like in forme unto them, are dented about the edges, the points whereof are prickely, as the ends are likewiſe: at the toppes of every ſtalke, which is not higher then the other, ſtandeth one round flower, larger or greater then of the other, but compoſed of the like blew threds as they.

10. *Globularia lutea montana.*
The mountaine yellow Daiſie.

11. *Bellis minor ſimplex ſylveſtris.*
The leſſer wilde white Daiſie.

12. *Bellis minor alba ramoſa.* Branched ſmall wilde white Daiſies.

10. *Globularia lutea montana.* The mountaine yellow Daiſie.

This yellow Globe flower hath many thicke, hard, ſmooth, round pointed leaves ſpread into ſundry heads on the ground, from among which ſpring ſundry ſtiffe ruſhlike ſtalkes about a foote high, with a joynt towards the middle of them, and two ſmall upright leaves ſet thereat, each bearing on their toppes, a globelike round head of flowers incloſed in a skinne, which opening, a number of flowers appeare, thicke thruſt together, like unto a head of Scabions, each flower being ſet in a rough purpliſh huske conſiſting of five ſweete faire yellow leaves laid ſtarre faſhion, with tenne long threds in the middle, ſtanding about a ſmall round umbone, having a pale flat bicorned pointell riſing out thereof, which umbone growing ripe is rough, and conteineth within it an hard ſhell, opening at the toppe into foure parts, wherein lie round flat, blacke ſeed, divided as it were with a ſmall cut; the roote is white, a foote long, and of a ſmall fingers thickneſſe, with a thicke browniſh barke, and a hard wooddy pith within, divers long fibres iſſuing out therefrom, whoſe taſte is drying, and ſent quicke and heady, the leaves being bitter and ſharpe withall.

11. *Bellis minor ſylveſtris ſimplex.*
The leſſer wilde white Daiſie.

The ſmall common ſingle field Daiſie hath many thicke and ſomewhat long greene leaves, lying upon the ground, ſmall at the bottome, broad and almoſt round at the point, and a little dented about the edges; from among which riſe many very ſlender, weake, and naked ſtalkes, or rather footeſtalkes, of two, three or foure inches high, bearing every one a ſmall greene head, from whence riſe many ſmall white leaves, ſet about a yellow thrumme or head in the middle, ſometimes the greene leaves will be found to be much larger in one place then another, and the flower likewiſe in ſome will be reddiſh at the ends, and ſometimes underſtained, and yet is but all one kinde or ſort, and not divers as ſome would have it: the roote is many ſmall white fibres.

12. *Bellis minor alba ramoſa.*
Branched ſmall wild white Daiſie.

This ſmall Daiſie differeth very little from the laſt Daiſies, but that the leaves are a little ſhorter and more dented about the edges, and the ſundry ſmall ſtalkes beare ſuch like leaves on them at the joynts where they branch forth into many parts, with ſuch like ſmall white flowers at their toppes.

13. *Bellis hortenſis multiplex.* Double Daiſies.

This differeth very little from the laſt, either in the leaves or manner of growing, the chiefeſt difference conſiſteth in the flowers, which in ſome are all white, but compoſed of ſundry rowes of leaves, others of a whitiſh red, or more white then red, or rather white leaves diſperſed among the red and others of other varieties, as I have formerly expreſſed them in my Booke.

13. *Bellis hortenſis multiplex.*
Double Garden Daiſies.

The Place.

The firſt groweth every where by hedge ſides, in the borders of fields, and other waſte grounds. The ſecond on the *Euganean* hils by *Padoa*. The third on Mount *Baldus*. The fourth came to us from *Virginia*. The fifth groweth on the Mountaines among the *Switzers*. The ſixth in ſandy barren places in the Ilands of *Stœchades*, which are over againſt *Marſelles*. The ſeaventh was firſt brought me out of *Italy*, by Mr. Dr. *Flud*, with many other ſeedes, that grew in the Garden of *Piſa*, in the Duke of *Florence* his Dominions, but of whence it is naturall, I have not yet certainely knowne, whether of *Candy* or any other place. The eighth groweth about *Mompelier*, and in many other places both of *France* and *Italy*. The ninth, grow on the hils in the Kingdome of *Granado*, there gathered by Dr. *Albinus*, and brought to *Bauhinus* as himſelfe relateth. The tenth, on the hils of *Æquicola* in *Naples*, as *Columna* maketh mention. The eleventh groweth in every field and medow almoſt. The twelfth was ſent from *Portugall*. The laſt in Gardens.

The Time.

All the ſixe firſt ſorts doe flower in *May* and *Iune*, but the other foure next ſorts later, that is, not untill the end of *Iuly* or beginning of *Auguſt*, and but ſometimes give good ſeed with us, the reſt all the Spring and former part of the Sommer.

The Names.

It is thought by moſt writers and others, that this was not knowne to any of the ancient Greeke authors, although ſome doe thinke that it is the ſame that *Theophraſtus* in his ſeaventh Booke, and ninth Chapter, calleth *Anthemis*, which is with him *ad terram foliatè ſpecies*, which *Gaza* tranſlateth *Nigella*, but it cannot be that. *Pliny* onely among the Latines maketh mention of *Bellis*, in his 26. Booke, and fifth Chapter, ſaying *Bellis* groweth in medowes, with a white flower ſomewhat reddiſh, which ſheweth us our ſmall wilde Daiſie, but that whereof he ſpeaketh in his 21. Booke and 8. Chapter which he calleth *Bellio* or *Bellius luteus*, as ſome have it, and hath 55. beards to crowne it, and is a field flower is not certainely knowne what herbe it ſhould be, yet many thinke the place corrupted, and to be otherwiſe read, but howſoever it be, he maketh it knowne no better. Some would have the name *Bellis* to be taken from *Belus* the King of *Danaus*, whoſe fifty daughters, being married to their fifty husbands, did the firſt night of their marriage make a mournefull maſſacre, every one of their husbands excepting one: ſome derive the word *a bello quaſi, bellis præſidium*, ſome alſo from the *French* word *Marguerites*, doe call the leſſer wilde ſort *Herba Morgarita*. The firſt ſort is called of divers *Conſolida media*, and the common ſmall or field Daiſie, called *Conſolida minor*: yet *Matthiolus* maketh a ſort of them to be *minor*, but no other liketh of that diviſion. *Brunfelſius* called it *Oculus bovis*, and *Bupthalmus*, and *Tabermontanus Bellium majus*, but all other authors *Bellis major*. The next two that follow, that is the fifth and the ſixth have their names in their title, as *Bauhinus* who firſt ſet them forth hath called them. The fourth I have ſo entituled it, as fitteſt thereunto. The ſeaventh was brought me with the title *Bellis ſpinoſa Patris Mutii*, who was Preſident over the Dukes garden at *Piſa*, at that time that Dr. *Flud* brought me the ſeedes thereof from thence, but *Lobel* calleth it *Bellis ſpinoſa elatior, & fruticoſior herbariorum bullatis aureis floribus*. The eighth is called by *Lobel Bellis cærulea, Globularia Monſpelienſium, Aphyllanthes* by *Anguilara* and *Camerarius*, *Bellis montana* by *Cæſalpinus*, and *Scabioſæ pumilum genus* by *Cluſius*, as he doth the ninth *Scabioſa montana minor repens*, but not rightly in my minde, ſeeing himſelfe in the deſcription ſaith, that the leaves and ſeede are like the other blew Daiſie. The tenth is by *Columna* called *Globularia lutea montana*. The eleventh is called *Bellis minor ſylveſtris* and *Conſolida minor & minima*, of divers *Solidago minor*, by others and *Primula veris* by many. The twelfth and laſt have their titles beſt befitting them. The *Italians* call both ſorts, *Fior de prima vera*, and the leſſer *Margarite*, and *Fior de*

prima vera gentile. The *French* call them both *Marguerites* and *Paſquets*, yet uſually they call the leſſer *Margueritons*. The *Germanes* call the greater *Genſsblum*, and the leſſer *Maſslieben oder zeitloſen*. The *Dutch* call the great ſort *wild oft groote Madelienen*, and the leſſe *Madalienen*, and *Margrieten*. We in *Engliſh* call the greater the great Daiſie, and Maudelinewort, and the other the leſſer or field Daiſie, &c.

The Vertues.

The greater wild Daiſie is a wound herbe of good reſpect, often uſed and ſeldome left out in thoſe drinkes or ſalves that are for wounds, either inward or outward: both it and the ſmall are held by the moſt to be cold and dry, yet *Dodonæus* ſaith they are cold and moiſt, which none other doth allow of: for the drying qualities doe more properly conſolidate, the juice or diſtilled water of either of them doth much temper the heat of choller, and refreſheth the liver and other inward parts. It is ſaid that they looſen the belly that is bound (which *Lobel* contradicteth, and true judgement doth the ſame) being taken in a ſallet with oile and vinegar, or the broth of fat fleſh wherein the leaves hereof and a few Mallowes have beene boyled: they helpe to cure the wounds of the breaſt made in the hollowneſſe thereof, if a decoction be made of them and drunke; the ſame alſo doth cure all ulcers, and puſtles in the mouth or tongue, or in the ſecret parts: the leaves bruiſed and applyed to the cods, or to any other parts that are ſwollen and hot, doth reſolve it, and temper the heat; they are alſo much commended that a decoction be made hereof and of Wallwort, and *Agrimony*, and the places fomented, or bathed therewith warme, that are afflicted either with the palſie, the Sciatica, or the gout, to give a great deale of eaſe of paine: the ſame alſo diſſolveth and diſperſeth the knots or kernels that grow in the fleſh of any part of the body, and the bruiſes and hurts that come of fals and blowes; they are alſo uſed for ruptures, or other inward burſtings with very good ſucceſſe: an ointment made thereof doth wonderfully helpe all wounds, that have inflammations about them, or by reaſon of moiſt humours having acceſſe unto them, are kept long from healing, and thoſe are ſuch for the moſt part that happen in the joynts of the armes, and legges: the juice of them dropped into the running eyes of any doth much helpe them: the ſmall Daiſie is held to be more aſtringent and binding then any other ſort.

CHAP. XXVIII.

Saniculâ. Sanicle.

THere be divers herbes that the learned writers have entituled Sanikle, from their eſpeciall properties in healing, as Avens, Beares eare, Corrallwort, Butterwort, and divers others, as they are remembred in their ſeverall places, and ſome in my former Booke, as the ſpotted and Beares eares Sanicle, whereof I thinke it not amiſſe to ſpeake a little here, and to give you their figures withall, but this that I here firſt propoſe unto you, is properly and peculiarly called Sanicle, ſimply without any other *epithite*, and thereof I finde no other ſort, although ſome have made *mas* and *fœmina*, accounting this the *mas*

1 *Sanicula vulgaris ſive Diapenſia.*
Ordinary Sanicle or Selfe heale.

2 *Pinguicula ſive Sanicula Eboracenſis.*
Butterwort or Yorkeſhire Sanicle.

and

3. *Sanicula guttata.*
Spotted Sanicle.

4. *Sanicula Alpina sive Cortusa Matthioli.*
Beares eare Sanicle.

andle *Astrancia nigra Dioscoridis*, to be the *fœmina*, but yet I thinke fit also to adjoyne hereunto, the *Pinguicula* or Butterwort, called of some *Sanicula Eboracensis* and an *American Cortusa*, for the properties and use sake, although differing in forme one from another. The description of the ordinary Saniele is thus. It sendeth forth many great round leaves, standing upon long browniſh stalkes, every one somewhat deepely cut or divided into five or sixe parts, and some of those cut in also, somewhat like the leafe of a Crowfoote or Doves foote, and finely dented about the edges, smooth and of a darke greene shining colour, and sometimes reddish about the brimmes; from among which riseth up small round greene stalkes, without any joynt or leafe thereon, saving at the toppe, where it brancheth out into flowers, having a leafe divided into three or foure parts, at that joynt with the flowers, which are small and white, starting out of small round greenish yellow heads, many standing together in a tuft; in which afterwards are the seedes contained, which are small round rough burres, somewhat like unto the seeds of *Clevers*, and sticke in the same manner, upon any thing that they touch: the roote is composed of many blacke strings or fibres set together, at a little long head, which abideth with the greene leaves all the winter and perish not.

2. *Pinguicula sive Sanicula Eboracensis.* Butterwort.

Butterwort hath divers fat and long leaves lying upon the ground about the roote, broad at the bottome and pointed at the end, of a pale greene colour on the upperside, and white underneath, folded together at their first rising which then are more white, from among which arise two or three slender naked stalkes, about an handbreadth high, bearing onely one flower at the toppe of every one, set in a small greene huske, made somewhat like a Violet flower or those of the Larkes heeles or spurres, having a small tayle or spurre behinde, in some of a purple, in others of a more blew colour, and in some white: after the flowers are past, come in their places small pointed round heads, wherein is contained small long blacke seede: the roote is composed of divers small white fibres or strings which dye not but abide with the greene leaves upon them all the Winter.

3. *Sanicula guttata.* Spotted Sanicle.

Having given you the description hereof and the varieties in my former Booke, I shall here rather point at it, then fully declare that it hath roundish leaves, greene above and grayish underneath, and reddish withall, the toppe of the branched stalke is stored with many small five leafed white flowers, so finely spotted with red spots, that they seeme to be pricked thereon.

4. *Sanicula Alpina sive Cortusa Matthioli.* Beares-eare Sanicle.

This also being there described at large needeth the lesser relation, that it hath larger and more crumpled hairy round leaves then the last: the stalkes also lower, and bearing sundry small pendulous purple flowers.

5. *Sanicula sive Cortusa Americana fruticosa.* The Shrubbe Sanicle of *America*.

The shrubby Sanicle of *America*, hath sundry almost round leaves lying on the ground each upon a little long footestalke divided at the edges into two parts, dented likewise about the brimmes, from among which rise hard wooddy stalkes neere two foote high, having such like leaves thereon as grow below and branching forth with

ſundry ſmall white ſtarrelike flowers in a tuft together at the toppes.

The Place.

The firſt is found in many ſhadowye woods and other places of this land. The ſecond in the common fields and ſundry bogs, on the hils in *Yorkeſhire* chiefly; in many places alſo of the Weſt Country, and *Wales*, and likewiſe in a Common, about a mile from *Oxford*, neare a village called *Herington*. The third and the fourth as *Cluſius* ſaith, groweth in all the *Auſtrian* and *Stirian* hils in the ſhadowy places of them. The laſt came from the backe part of *Virginia* called *Canada*.

The Time.

The firſt and ſecond flower not untill *Iune*, and their ſeede is ſoone ripe after: the other two next flower much earlier and ſometimes againe in *Autumne*. The laſt flowreth in *Iuly*.

The Names.

I have not found that any of theſe Sanicles were knowne to any of the ancient Greeke or Latine authors, but are as many other vulnerary, and other herbes found out and named by later writers. For the firſt it hath his name *Sanicula a potiore ſanandi munere*, it is alſo called *Diapenſia*, by *Brunfelſius*, *Matthiolus*, and *Lobel*, and by *Tabermontanus*, *Conſolida quinquefolia*, for *Matthiolus* maketh it his fourth kinde of *Quinquefolium*. *Fabius Columna*, would referre it to the third *Sideritis* of *Dioſcorides*: but of moſt writers it is generally called *Sanicula*, and ſome as I ſaid before call it *mas*, becauſe they would make the *Aſtrantia nigra Dioſcoridis*, (ſet forth in the third Claſſis of this worke, which is of purging plants, and 23. Chapter, under the title of *Helleborus niger Saniculæ folio major*, the great purging Sanicle) to be the *femina*. It is called by the *Italians Sanicola*, by the *Germanes* and *Dutch Sanikel*, by the *French Sanicle*, and by us *Sanickle*. The other was firſt called *Pinguicula* by *Geſner in deſcriptione montis fracti*, and from him all others doe ſo call it: ſome alſo with us *Sanicula Eboracenſis*, becauſe it groweth ſo plentifully in *Yorkeſhire*: *Lugdunenſis* calleth it *Cucullata*, and thinketh it may be *Crias Apulei*, *Geſner* thought it to be *Dodecatheon Pliny*, others *Lingula Pliny*, and ſome, as *Geſner Viola humida aut paluſtris*, *Bauhinus* in putting it among his Sanicules calleth it *Sanicula montana flore calcari donata*. We in *Engliſh* doe call it Butterwort, and Butter roote, becauſe of the *vnctuoſitie* of the leaves, or elſe of fatning as *Gerard* ſaith, but untruely, for they call it white rot and not white roote as *Gerard* ſaith, for the Country people doe thinke their ſheepe will catch the rot, if for hunger they ſhould eate thereof, and therefore call it the white rot, of the colour of the herbe, as they have another they call the red rot, which is *Pedicularis* red Rattle. The third is called *Sanicula montana altera* by *Cluſius*, and *Alpina*, and *guttata* by *Camerarius* and others, by *Lobel Gariophyllata ſive Geum Alpinum recentiorum folio hederaceo*. The fourth *Matthiolus* called *Cortuſa* having received it from *Cortuſus*, and reckoneth it among the *Avens*, and thereupon *Lobel* calleth it *Caryophyllata Veronenſium flore Saniculæ urſinæ*; *Cluſius* calleth it his firſt *Sanicula montana*, and others *Alpina*: The laſt for ſome reſemblance was called *Cortuſa* by the *French*, and *Americana* added to diſtinguiſh it.

The Vertues.

Sanicle is bitter in taſte, and thereby is heating and drying in the ſecond degree, it is aſtringent alſo, and therefore exceeding good to heale all greene wounds ſpeedily, or any ulcers, impoſtumes, or bleedings inwardly; it doth wonderfully helpe thoſe that have any tumour in their bodies in any part, for it repreſſeth the humours, and diſſipateth them, if the decoction or juice thereof be taken, or the powder in drinke, and the juice uſed outwardly; for there is not found any herbe that can give ſuch preſent helpe, either to man or beaſt, when the diſeaſe falleth upon the lungs or throate, and to heale up all the maligne putride or ſtinking ulcers of the mouth, throat, and privities, by gargling or waſhing with the decoction of the leaves and roote made in water, and a little hony put thereto; it helpeth to ſtay womens courſes, and all other fluxes of blood, either by the mouth, urine, or ſtoole, and laskes of the belly, the ulceration of the kidneyes alſo and the paines in the bowels, and the *gonorrhea* or running of the reynes, being boyled in wine or water and drunke, the ſame alſo is no leſſe powerfull, to helpe any ruptures or burſtings uſed both inwardly and outwardly: and briefely it is as effectuall in binding reſtraining, conſolidating, heating drying, and healing, as Comfrey, Bugle, or Selfeheale, or any other of the Conſounds or vulnerary herbes whatſoever. Butterwort is as one writeth to me a vulnerary herbe, of great eſteeme with many, as well for the rupture in Children as to heale greene wounds; the Country people that live where it groweth; doe uſe to annoint their hands when they are chapt by the winde, or when their Kines Vdders are ſwollen by the biting of any virulent worme, or otherwiſe hurt, chapt or rift, the poorer ſort of people in *Wales* make a Syrupe thereof, as is of Roſes, and therewith purge themſelves and their children: they put it likewiſe into their broths for the ſame purpoſe which purgeth flegme effectually: they alſo with the herbe and butter make an ointment ſingular good againſt the obſtructions of the liver, experienced by ſome Phyſitions there of good account.

CHAP. XXIX.

Primula veris pratenſis & ſylveſtris. Primroſes and Cowſlips.

THere is ſo great a variety in theſe ſorts of plants, Primroſes and Cowſlips, whereunto for likeneſſe both in forme and quality, is to be joyned the little army of *Auricules* Eeares eares, (or *French* Cowſlips) as they are called, eſpecially in the various colours of their flowers, that to deſcribe them all againe, would but too much augment this volume, I will therfore here but give you ſome figures of thoſe, deſcribed fully in my former Booke, and the relation of ſuch others as have ſince the publiſhing thereof come to our knowledge.

1. *Primula veris Turcica Tradeſcanti flore purpureo. Tradeſcants Turkie* purple Primroſe.

The leaves of this Primroſe are ſo like unto other Primroſes, that they can very hardly be diſtinguiſhed untill the flowers appeare, but the chiefeſt difference in the leaves is, that they are ſomewhat longer, rounder pointed and a little reddiſh at the very bottome of the leaves: the flowers are as large as any other Primroſe or rather larger, made of five leaves like unto them, but of a delicate violet purple colour, the bottome of them yellow, circled

Primula veris vulgaris.
The ordinary field Primrose.

Primula Hesketi verſip
Heskets Cameleon P ellis.

Primula veris flore purpureo Turcica.
The *Turkie* purple Primrose.

Paralyſis flore pleno.
Double Paigles.

Paralytica Alpina major.
The greater Birdes eye.

Paralytica Alpina minor.
The lesser Birdes eye.

Aricula ursi lutea.
The yellow Beares eares.

Auricula ursi minima alba.
Small white Beares eares.

circled as it were with a deepe Saffron like yellow, which addeth a greater grace thereunto; in other things it is like unto the ordinary Primroſes.

Of this kinde there is alſo another ſort little differing from it in any thing ſave in the colour of the flower, which in this is crimſon, as in the other purple. *Flore chermeſino.*

2. *Paralyſios variæ ſpecies.* The divers ſorts of Cowſlips.

Of the various ſorts of Cowſlips, I have given you all the ſtore I know are extant, and therefore will deſcribe none of them here, but referre you to my former Booke, where you ſhall finde them. *duplici. 1.*

3. *Auriculæ urſi varietates.* The varieties of Beares eares or *French* Cowſlips. *Purpureo vario 2.*

I have there alſo divided the varieties of the Beares eares or *French* Cowſlips into three colours, that is purple or red, white, and yellow, of the reſt that I have not there ſpoken, I will here make but briefe mention, of the difference in leafe and flower onely, without any larger deſcription. *Purpureo ſaturo flore majore 3.*

The bright crimſon hath leaves of a middle ſize more greene then mealy, and flowers of a bright crimſon colour larger then the blood red. *Purpureo ſaturo flore minore. 4.*

The deepe crimſon velvet colour.

The double purple hath the purple flower once more double then the ſingle, but is not conſtant. *Sanguineo. 5.*

The ſtript purple differs in leafe little or nothing, from the ordinary purple, nor yet in flower, but onely that it is variouſly ſtript with a kinde of whitiſh bluſh colour; ſome of theſe will change wholly into the one or the other colour, as all or moſt of the ſeverall ſorts of other ſtript flowers, whether *Tulipas*, Gilloflowers, &c. are obſerved often to doe, yet as in them ſo in theſe, if they change into the deeper colour, they ſeldome or never returne to be marked, as they will if they change into the lighter. *Cœruleo. 6.*

Cœruleo. 7

The heavens blew hath the leafe broader and of a duskie yellowiſh greene colour, the flowers being of a blewiſh colour tending to a purple. *8. Flore cæruleo folio Boraginis.*

The paler blew is ſomewhat like unto the laſt in the greene leafe, the flower being of a paler blew.

Borage leafed blew Beares eares is ſufficiently expreſſed in my former Booke. *9. Purpuro cæruleo incano folio.*

The *Collie* as the *French* call it, or the farre Collier as we in *Engliſh*, hath a pale greeniſh leafe without dents, and ſomewhat a large flower, and of a dainty violet purple colour, ſomewhat ſad but very lively.

The *Camberſine* hath a ſmaller greene leafe without dents or very few, and the flower neere that of the faire Collier, but not altogether ſo lively nor ſo great a flower. *Flore cramoſino. 10.*

A purpliſh blew with a white bottome, and a mealy leafe. *Holoſericeo. 11.*

The *Poutrine* or blood red hath a yellowiſh greene leafe, ſomewhat ſmall and long, with a few dents on the edges, the flowers are of a blood red colour with a yellow eye, and but few upon a ſtalke. *Purpureo Rubro vario. 12.*

The party coloured red and white, we heare for certaine of ſuch an one, but we have not as yet ſeene it.

There are ſundry ſorts of bluſhes, paler or deeper, more or leſſe beautifull by much then others, as alſo wonderfull much variety of each of the former colours not to be expreſſed, in that from the ſowing of the ſeede ariſeth new colours almoſt every yeare. *Carneo colore. 13.*

The pure white, Snow white, or Paperwhite, as they are called by divers, hath flowers of a pure Snow white colour, but ſmaller then the next. *Flore niveo. 14.*

White hath a little larger flower, but is not ſo pure a white as the former, but yet commeth white from the firſt budding, and not yellowiſh as in the next. *Flore a bo 15.*

The common white hath ſundry flowers upon a ſtalke, of a reaſonable ſize, whoſe buds are yellowiſh at the firſt, and become white afterwards. *Flore albido, vel pallido 16.*

Other ſorts may be reckoned to theſe whites, and ſome may be ſet under the bluſhes of the paler ſorts. *17. Flore luteo.*

Of the great yellow there are ſundry different ſorts, all of them having large mealy leaves, and great tufts of flowers, ſome deeper or paler then others, and ſome greater or leſſer alſo. *Magno. 18*

The Lemman colour is of a delicate pale yellow colour and of a middle ſize both leafe and flower. *Limoniaco. 19.*

Straw colour, Shamwey colour. *Straminео 20. 21.*

A number of other ſorts of plaine yellowes there be, impoſſible to be diſtinguiſhed. *Verſicolore luteo. 22.*

The diverſities likewiſe of the diverſified or variable yellowes are numberleſſe, which although their ground is yellow yet are ſo mixed and varied thereupon that I cannot expreſſe them. *Caneſcentibus foliis.*

The leather coate is larger or leſſer, deeper or paler one then another, they have all large mealy leaves, yet not ſo much as in the greateſt yellow, but yet ſeemeth to be produced from thence they come ſo neere it. *Luteo fuſco. 23.*

Haire colour of divers ſorts. *Crinis coloris 24.*

Spaniſh bluſh. *Lutea rubra. 25.*

The Place and Time.

The purple and crimſon Primroſes came firſt from *Turkie* to us, and flowreth with other Primroſes very early in the Spring, and ſometimes againe in Autumne, The originall of the *Auricules* came firſt from the mountaines of *Germany*, *Hungary*, *Italy*, as the *Alpes* and *Pyrenees*, *&c.* but the greateſt variety hath riſen from ſowing of the ſeede, and many of them will flower twice in the yeare, *viz.* in *Aprill* and *May*, and then againe in *Auguſt* and *September*, if the Autumne proove temperate and moiſt.

The Names.

The purple Primroſe is ſaid to be called *Carchichek* by the *Turkes*. *Fabius Columna* referreth the Cowſlips to the *Aliſma* of *Dioſcorides*, and calleth them *Aliſma pratorum & ſylvarum*, others call them *Verbaſculum*. *Geſner Arthritica*, *Anguilara Dodecatheon*, but generally *Paralyſis* and *Herba Paralyſis*. The *Auricula urſi* is entituled by divers names, by ſundry authors as *Lunaria Arthritica*, and *Paralytica Alpina* by *Geſner*, *Primula veris pachyphyllos* by *Lugdunenſis*. *Sanicula ſive Auricula urſi*, firſt by *Matthiolus*, and after by *Lobel*, and *Sanicula Alpina* by *Geſner* and *Bauhinus*, but uſually now adaies *Auricula urſi* by all, and thereafter we in *Engliſh* Beares eares or *French* Cowſlips.

The Vertues.

Primroſes and Cowſlips are much uſed to be eaten in Tanſies Sallets, &c. by thoſe beyond Sea, and are accounted very profitable for paines in the head, and are accounted the beſt for that purpoſe next unto Betony, they are excellent good againſt any joynt aches as the palſie and to eaſe the paines of the ſinewes, as the names doe import.

port. Of the juice or water of the flowers of Cowslips, divers Gentlewomen know how to clense the skin from spots or discolourings therein, as also to take away the wrinckles thereof, and cause the skinne to become smooth and faire, the rootes made into a decoction and taken, easeth the paines of the backe and bladder, opening the passages of urine which was the cause thereof; they are likewise often used in wounds either greene or old, and that to very good purpose. The Beares eares according to their name Sanicle, are no lesse powerfull in healing then the common, as also for the palsie and trembling of the joynts, *Clusius* saith that the mountainers that hunt after wilde beasts doe use the rootes of Beares eares to helpe either paines in the head, or the giddinesse that may happen thereto, by the sight of such fearefull *precipices* or steepe places, that they must often passe by in following their game, and are admitted as good Wound herbes as the former Cowslips.

CHAP. XXX.

Alchymilla. Ladies Mantile.

VNto the Sanicles set downe in the last Chapter, I thinke it fittest to place this next unto it, because both for forme and quality it is so assuredly like it, that it is called of divers the greater Sanicle, and will adde thereunto another sort thereof, which hath not beene formerly well knowne.

1. *Alchymilla major vulgaris.* Common Ladies Mantle.

Our common Ladies Mantle is very like to the former Sanicle, having many leaves rising from the roote, standing upon long hairy footestalkes, being almost round, but a little cut in on the edges, into eight or tenne parts, more or lesse, making it seeme like a starre, with so many corners and points, and dented round about, of a light greene colour, somewhat hard in handling, and as if it were foulded or plaited at the first, and then crumpled in divers places, and a little hairy, as the stalke is also which riseth up among them, to the height of two or three foote, with a few such leaves thereupon, but smaller, and being weake is not able to stand upright, but bendeth downe to the ground, divided at the toppe into two or three small branches, with small yellowish greene heads, and flowers of a whitish greene colour breaking out of them, which being past, there commeth small yellowish seede like unto Poppy seede, the roote is somewhat long and blacke, with many strings and fibres thereat.

1. *Alchymilla major vulgaris.*
Common Ladies Mantle.

2. *Alchymilla minor quinquefolia.*
Cinkefoile Ladies Mantle.

This small Ladies Mantle, hath also a few smaller and smoother greene leaves, rising from the small blacke fibrous roote, set upon long footestalkes, but divided at the edges into five corners or points, and somewhat deepelier dented about the brimmes then the former; from whence two or three small weake bending stalkes doe rise, not halfe a foote high: the flowers that grow at the toppes are smaller, but alike according to the bignesse of the plant, and of the same herby or greene colour.

The Place.

The first groweth naturally in many pastures and wood sides, both in *Hartford* and *Wiltshire*, and in *Kent* also, as in *Kingwood* neere *Feversham*, in the pastures nigh *Tidnam*, and *Chepstow*, and in other places of this land; the other groweth on St. *Bernards* hill among the *Switzers*.

The Time.

The first flowreth in *May* and *Iune*, the other not untill *August*, but both abide after seede time, greene all the Winter after.

The Names.

It was not knowne by name unto the ancient writers, as can be gathered, and although *Brunfelsius* and some others thought it to be *Leontopodium* or Lions foote, deceived by the name, because divers nations have so called it, from the forme or likenesse of the leafe, yet is it not that of *Dioscorides*, as may plainely appeare by his description thereof. It is usually called *Alchymilla* by most writers, because as some thinke the Alchymists gave such commendations of it. It is called also of *Matthiolus*, *Lugdunensis*, and others *Stellaria*, from the forme of the leafe, that with the corners resemble a starre, but there are divers other herbes called *Stellaria* by divers authours, and some also call this *Pes Leonis*, and *Pata Leonis*: others call it *Sanicula major*, not without good reason. *Cordus in historia de plantis*, calleth it *Drosera*, *Drosium*, and *Psiadeion* from the *Germane* name *Sinnaw*, because the hollow crumplings and the edges also of the leaves, will containe the dew in droppes like pearles, that falleth in the night. *Bauhinus* calleth the other *Alchymilla Alpina Quinquefolia*. The *Italians* call it *Stellaria*, and *Stella herba*. The *French Pied de lyon*. The *Germanes* as I said before *Sinnaw*, and some *Lewenfuss*, and *Vnserfrawen mantel*. The *Dutch Onser urawen mantel*. And we in *English* Our Ladies Mantle, and great Sanicle, and some Lions foote, or Lions paw, or *Padelyon* after the *French*.

The

The Vertues.

Ladies Mantle is more cooling then Sanicle, and therefore more proper for thoſe wounds that have inflammations, and more aſtringent binding and drying, and therefore is more effectuall to ſtay bleedings, vomitings, fluxes in man or woman of all ſorts, and bruiſes by fals or otherwiſe, and to helpe ruptures, it helpeth alſo ſuch maides or women that have overgreat flagging breaſts, cauſing them to grow leſſe and hard, being both drunke, and outwardly applyed, and ſerveth alſo to ſtay the whites in them, wherein it is ſo powerfull that it is uſed as a ſurfuling water alſo, the diſtilled water drunke continually for twenty daies together, by ſuch women as are barren and cannot conceive, or retaine the birth after conception, through the too much humidity of the matrice, and fluxe of moiſt humours thereunto, cauſing the ſeede not to abide but to paſſe away without fruite, will reduce their bodies to ſo good and conformable an eſtate, that they ſhall thereby be made more fit and able to retaine the conception, and beare out their children, if they doe alſo ſit ſometimes as in a bath, in the decoction made of the herbe. It is accounted as one of the moſt ſingular wound herbes that is, and therefore the *Germanes* extoll it with exceeding great praiſe, and never dreſſe any wound, either inward or outward, but they give of the decoction hereof to drinke; and either waſh the wound with the ſaid decoction, or dippe tents therein, and put them thereinto, which wonderfully dryeth up all the humidity of the ſores, or of the humours flowing thereunto, yea although they be fiſtulous and hollow, and abateth alſo ſuch inflammations, as often happen unto ſores: but for freſh or greene wounds or cuts, it ſo quickely healeth them up, that it ſuffereth not any quitture to grow therein, but conſolidateth the lippes of the wound, yet not ſuffering any corruption to remaine behinde: it hath formerly beene much accounted of by Chymiſts, who have affirmed that the juice hereof will conſtraine the volubility of Mercury, and make it fixt, from whence as it is thought it tooke the name, but theſe idle fancies are now quite worne out, as I thinke.

CHAP. XXXI.

Solidago Saracenica. Saraſins Conſound.

THere have beene divers herbes that have beene miſtaken and ſet forth for the right Saraſins Conſound, we will therefore ſhew you here in this place ſome of them that are not right, with the true one alſo.

1. *Solidago Saracenica vera Salicis folio.*
The true Saraſins Conſound with willow leaves.

The true Saraſins Conſound groweth very high ſometimes, with browniſh ſtalkes, and other whiles with greene and hollow, to a mans height, having many long and narrow greene leaves ſnipt about the edges ſet thereon ſomewhat like unto thoſe of the Almond, or Peach tree, or Willow leaves, but not of ſuch a white greene colour; the toppes of the ſtalkes are furniſhed with many pale yellow ſtarrelike flowers, ſtanding in greene heads, which when they are fallen, and the ſeed ripe, which is ſomewhat long, ſmall, and of a yellowiſh browne colour, wrapped in downe, is therewith carryed away with the wind, the roote is compoſed of many ſtrings or fibres, ſet together at a head, which periſh not in winter, but abide, although the ſtalkes dry away, and no leaſe appeareth in Winter; the taſte hereof is ſtrong and unpleaſant, and ſo is the ſmell alſo.

2. *Solidago Saracenica major.*
The greater Saraſins Conſound.

This greater *Solidago* differeth not much from the former, riſing up with upright hard round hollow ſtalkes, as high as it, with many darke greene leaves at the firſt, ſet at the head of the roote, which afterwards riſe up with the ſtalkes, and are ſet there without order, ſomewhat larger then they, and dented about the edges; the flowers are much greater with more and yellower long leaves ſtarfaſhion, ſtanding in greene heads many together, wherein after they are paſt, are contained the ſeede, which with the downe thereof flieth away with the winde, in the like manner as the former doth, the rootes are compoſed of a great buſh of white ſtrings, or white fibres growing very ſtrongly in the ground, and ſhooting forth ſtringo n all ſides, which produce new plants, encreaſing in a ſmall time, and overſpreading a great quantity of ground, the head of leaves is ſomewhat browne at the firſt ſhooting out of the ground, and ſo is the head of the roote before the Spring, and are of a bitter taſte, and binding withall.

3. *Solidago Saracenica ſive Germanica ſiliquoſa.*
The *Germane* Conſound with ſmall cods.

This Conſound riſeth up with great round wooddy ſtalkes, to as great an height as the former, or more, but

3. *Solidago Saracenica ſive Germanica ſiliquoſa.*
The *Germane* Conſound with ſmall cods.

are

are ſo weake by reaſon of the length and weight of leaves thereon,that they cannot ſtand upright,but fall downe upon the ground, bearing many darke greene leaves thereon, long and narrow like the firſt, with a white ribbe in the middle, ſnipt or dented about the edges,and many ſmaller yellowiſh flowers at the toppes of them,which turne into very ſmall and long round darke pods, as ſmall and long as thoſe of *Sophia* or Flixeweede, and ſmall browniſh ſeedes within them, of an hot and quicke, ſharpe and unpleaſant taſte withall, as the herbe it ſelfe is, but much more, the roote in time groweth to be very great, even of the bigneſſe of a mans arme, and very deepe alſo (for ſuch I have digged up in my owne Garden) of a ſtrong unpleaſant ſavour and taſte, ſharper then Creſſes, and very like unto that of Flixeweede, abiding many yeares: but the ſtalkes periſhing downe to the ground, and ſhooting forth anew in the Spring.

4. *Solidago Saracenica altera ſive tertia Tragi.* *Tragus* his *Germane* Conſound.

This other *Germane* Conſound, is ſomewhat like both in ſtalkes and leaves unto the middle kinde of Neppe, with long leaves, being white as they are, the flowers ſtand at the toppes of the ſtalkes, many together upon ſmall round greene heads, very like unto the firſt ſort, being ſmall and yellow, which after they are paſt, and the heads with ſeed are ripe, open themſelves, and with the downe in them, is carryed away by the wind, in the ſame manner: the roote creepeth in the ground, and ſhooteth up branches round about; the taſte of the herbe is bitter, whereby it is found to be drying, and of a piercing quality.

The Place.

All theſe doe grow in moiſt and wet grounds, by woods ſides, and ſometimes in the moiſt places of the ſhadowy groves, as alſo by water ſides.

The Time.

They flower in *July*, and the ſeede of the two firſt, is ſoone ripe, and carryed away with the winde after; the third hath not his pods and ſeede ripe untill the end of *Auguſt*, or beginning of *September*.

The Names.

None of theſe herbes are of ancient, but later invention and appellation; it is called *Solidago* and *Conſolida* from the old Latine word *Conſolidare*, which in the barbarous Latine age did ſignifie, to ſoder, cloſe, or glue up the lips of wounds, and *Saracenica*, becauſe the *Turkes* and *Saraſens* had a great opinion thereof, in healing the hurts and wounds of their people, and were accounted great Chirurgions, and of wonderfull skill therein, whom the Chriſtians followed and called it thereafter, others called it *herba fortis* from the ſtrong ſent and taſte as it is thought. *Tragus* after he had deſcribed the *Solidago Saracenica vera*, addeth two ſorts more, the one which is his ſecond, is the *Lyſimachia cærulea ſpicata*, and the third which is the laſt here, *Bauhinus* calleth it *Conizæ affinis Germanica*, referring it to the *Conyza's* or Fleabanes, but I have thought it fitter to place it here. *Tragus* calleth the firſt *Solidago Saracenica prima*, and ſaith that *Brunfelſius* wrote very largely thereof, and yet *Bauhinus* quoteth not *Brunfelſius* to have called it ſo, but that he called the *Bellis ſylveſtris minor*, to be *Solidago Conſolidæ ſpecies*, divers have thought the *Virga aurea* to be it, and ſo doth *Bauhinus* alſo, and therefore ſaith that *Tragus* his firſt *Solidago* is the *Virga aurea anguſtifolia ſerrata*, *Tabermontanus* calleth it *Conſolida aurea*. The ſecond is called by *Lugdunenſis*, *Solidago Saracenica major*. The third I preſume is the ſame that *Lobel* giveth us the deſcription of in his *Adverſaria*, and the figure in his Obſervations, yet maketh the heads with ſeed to flye away with the wind as the others doe, but ſurely the figure hereof, doth ſo truely repreſent this plant, that I doe here ſet forth unto you, as no other can come neerer unto it, and therefore I am perſwaded that he was miſtaken in the heads of ſeede, which as I ſhew you in this, give ſmall long pods with ſmall browne ſeed therein; or elſe there is another ſo like this as can be, whoſe ſeed with the downe is carryed away with the winde. The laſt is as I ſaid *Tragus* his third *Solidago Saracenica*, which he calleth *Herba vulneraria ad fluvium de Pfrim*. The *Germanes* as it is thought firſt called it *Heidniſch Wundtkraut*, that is *Vulneraria Turcica* Heatheniſh Woundwort, from whence came the name *Solidago Saracenica*, and the *French* thereafter *Conſoulde Sarazine*, and ſo all other nations in their ſeverall tongues.

The Vertues.

Among the *Germanes* this Wound herbe, is not onely of eſpeciall account, but even preferred before all other of the ſame quality, be it Bugle or Sanicle, or whatſoever elſe, for it is hot and dry almoſt in the third degree, and binding withall: being boyled in wine and given to drinke, it helpeth the indiſpoſition of the Liver, and freeth the gall from obſtructions, whereby it is good for the yellow jaundiſe, and for the dropſie in the beginning thereof, as alſo all inward ulcers of the reines, or elſewhere, and inward wounds or bruiſes; and being ſteeped in wine, and then diſtilled, the water thereof drunke is ſingular good to eaſe all gnawing in the ſtomacke, or any other paines or torments in the body, as alſo the paines of the mother; and being boyled in water, helpeth continuall agues; and this ſaid water or the ſimple water of the herbe diſtilled, or the juice or decoction are all very effectuall to heale any greene wound, or old ſore or ulcer whatſoever, both cleanſing them from any corruption is bred in them, and healing them up quickely afterwards; the ſame alſo is no leſſe effectuall, for the ulcers in the mouth or throate, be they never ſo foule or ſtinking, by waſhing and gargling the mouth and throate therewith, and likewiſe for ſuch ſores as happen in the privy parts of man or woman, briefely whatſoever hath been ſaid of Bugle or Sanicle, may be found herein. The other ſorts of Conſounds doe runne the ſame courſe with this, and are as effectuall in a manner as it.

CHAP. XXXII.

Herba Doria ſive Aurea. *Dorias* his Woundwort.

BEcauſe this herbe doth notably differ, both from the former Conſounds, and the Golden roddes that ſhall follow, I have thought good to ſet it betweene them, whereof there are more ſorts then one, as they may beſt be referred.

1. *Herba Doria vulgaris.* The ordinary *Dorias* Woundwort.

This Woundwort hath many great thicke fleſhy long deepe greene leaves riſing from the roote, almoſt

1. *Herba Doria vulgaris.*
The ordinary *Dorias* Woundwort.

2. *Herba Doria minor Americana.*
Dorias Woundwort of *America.*

almoſt as long as Docke leaves, but thicker, ſharper at the points, ſmaller at the lower ends of them, and broadeſt in the middle, ſomewhat harſh or hard in handling, among which riſeth up but one great ſtalke for the moſt part, but exceeding high, above any man, whereon are ſet very ſparingly, ſcarſe two or three ſuch leaves, but ſmaller as grow below, at the toppes whereof ſtand a few yellow flowers, in greene ſcaly heads, greener then thoſe of the golden rodde, or of the former Conſound, which when they are ripe, are blowne away with the winde: the roote is not ſo great, as the plant would make ſhew it ſhould be, having many fibres ſet at the head together, which take ſtrong hold of the ground, and dyeth not, nor the leaves loſe their verdure in the winter, but ſpring afreſh every yeare.

2. *Herba Doria minor Americana. Dorias* Woundwort of *America.*

This ſtranger is ſo like the former in ſhew, that it cannot better be referred then unto the former, abiding greene all the winter, whoſe leaves are thicke ſomewhat long and narrow, but not halfe ſo great as the former, and of a paler greene colour, elſe for forme very like them: the ſtalkes which are many, and riſe not to halfe that height are round, and for the moſt part, leane downe, not being able, by the multitude of flowers and leaves thereon, to ſtand upright, which flowers ſtand upon longer, and greater greene ſcaly heads then the former, and are themſelves alſo greater, and more laide open, with many ſmall, long narrow leaves, which turne into a white moſſie downe, and is carryed away with the winde, the roote is compoſed of many blackiſh fibres.

3. *Conſolida aurea nemorum.* The golden Conſound.

This golden herbe hath divers long and narrow ſharpe pointed leaves, ſtanding at the toppe of the roote, very like unto *Dorias* Woundwort, but not ſo great, yet thicke like them, and of a darker greene colour, the ſtalkes riſe not much above a foote high, having here and there narrower long leaves on them, then below, the flowers that ſtand at the toppes of them, are larger then of the former, having many narrow long yellow leaves thereon, laide open like a ſtarre flower, with divers thrummes in the middle, the rootes are many ſmall white fibres, lik unto the Daiſies, the taſte thereof is ſomewhat ſharpe, and aromaticall, and aſtringent or binding withall.

The Place.

The firſt as *Lobel* ſaith, groweth neare the bankes of Rivers, in *Provence* and *Narbone* of *France.* The ſecond came from the *French* Colony in *America*, into *France*, for from *Veſpaſian Robin* of *Paris* I had it. The laſt in the thicke woods neere *Orleance*, as *Lobel* alſo ſaith, they doe all well abide in Gardens.

The Time.

The firſt and the laſt doe for the moſt part, flower a moneth before the ſecond, which is not in flower before *Auguſt* at the ſooneſt.

The Names.

The firſt is thought to have beene found out by *Andreas Doria*, the Generall of the Emperour, and the *French* Kings fleete, or at leaſt commended or commanded to be uſed for the reliefe of his Souldiers and Marriners, although

though *Lobel* ſeemeth to invert the name, from the *French*, *L' herbe Doree*, *herba Dorea*, *quaſi aurea herba*, and thinketh it may be the *Panax Chironium* of *Theophraſtus*, which he deſcribeth in the 12. Chapter of his 9. Booke, whoſe forme and properties there related, doe very fitly anſwer hereunto (yet ſome doe rather referre the *Bupleuron* Hares eare unto it) or elſe (as he ſaith) is one of thoſe *Panaces* of *Theophraſtus*, which *Pliny* in his 23. Booke, and 4. Chapter ſpeaketh of, found by *Chiron*, and called *Centaurium*, and called alſo *Pharnaceum*, of the King *Pharnaces*, who is ſaid alſo to finde it. *Geſner* in *hortis Germania*, ſaith it was called of ſome, *Panaces Chironium*, and *Tabermontanus* alſo calleth it, *Panax Chironium Theophraſti*, it is that *Limonium aliud*, that *Lugdunenſis* ſaith was ſo called of ſome Herbariſts, ſetting it forth in the Chapter of *Limonium*, and yet is the ſame that he ſet forth for the *Dorea Narbonenſium* of *Pena* and *Lobel*, in the Chapter of *Virga aurea*, although it ſeemeth he did not know ſo much, which kinde of error is very frequent in him. *Bauhinus* calleth it *Virga aurea major vel Doria*, The ſecond came to me under the ſame name that is in the title, which becauſe it can be no waies bettered, I thinke not fit to alter. The laſt *Pena* and *Lobel*, doe onely make mention of in their *Adverſaria*, by the name of *Conſolida aurea nemorum Limonij folijs*, and *Bauhinus* calleth it, *Virga aurea magno flore*.

The Vertues.

The properties of healing greene wounds, and old ſores is proper hereunto, being accounted as a meane in thē vertues, betweene the former Conſounds, and the golden rods that follow, and therefore it needeth not any further repetition, or amplification of the ſame things: but if it be the *Panax Chironium* of *Theophraſtus* as aforeſaid it ſhould then be availeable againſt the bitings of the viper, and the *Phalangium*, and other venemous Creatures, being given in wine inwardly, and annointed therewith, and the oyle outwardly; as alſo for old or foule ulcers, uſed with wine and oyle, and with hony for excreſcences in the fleſh, and to deſtroy the moths of garments, unto all which properties, both the ſmell and taſte ſo aromaticall in leaves and rootes, like unto that of wild Angelica, may very well conduce us to beleeve, for many both Phyſitions and Chirurgions in *France* doe much eſteeme thereof, and uſe it both inwardly and outwardly, in many medicines for their Patients, and to good effect.

CHAP. XXXIII.

Virga aurea. Golden Rod.

UNto the two ſorts of golden Rods, that are knowne and ſet forth by many writers, we have another ſort not yet knowne publikely, whoſe originall was in *America*.

1. *Virga aurea vulgaris.* The ordinary Golden Rod.

This Golden Rod, that is moſt common to our Country, riſeth up with browniſh ſmall round ſtalkes, halfe a yard or two foote high, but higher if it grow in a fat ſoile, or in a Garden, having thereon many narrow and long darke greene leaves, very ſeldome with any nickes or dents about the edges, and as ſeldome with any ſtrakes or white ſpots therein, and yet ſometimes and in ſome places, they are ſo to be found, divided at the tops into many ſmall branches, with divers ſmall yellow flowers on every one of them, which are turned one way, not looking ſundry waies, as all the flowers of the former kindes doe, which likewiſe being ripe, doe turne into downe, and are caried away with the winde, the roote conſiſteth of many ſmall fibres, which grow not deepe into the ground, but abideth all he Winter therein, ſhooting forth new branches every yeare, the old ones dying downe to the ground.

2. *Virga aurea ſerratis folijs.*
Golden Rod with dented leaves.

The ſtalkes of this Golden Rod, riſe not up ſo high as the former, but are as great, bearing larger, but ſhorter leaves thereon, and dented about the edges, the branches beare ſuch like flowers, facing one ſide of their ſtalkes as the former doth, and are turned into downe, flying away in the ſame manner, the roote is like the other.

3. *Virga aurea Americana.* Golden Rod of *America*.

The leaves of this Golden Rod, before it runne up to ſtalke, are as great as the laſt, being but narrow and long, yet broadeſt in the middle, and very ſharpe pointed at the ends, ſomewhat dented alſo about the edges, but leſſe then the former, and of a darke greene colour, the ſtalke is a little hairy, riſing higher then the laſt, or about a foote and a halfe high at the moſt, bearing yellow flowers all on one ſide, like the former, and flye in the winde, with the downe as the reſt, the roote is not much unlike the other, and abideth under ground in winter in the ſame manner, loſing all the old ſtalkes. I have given but one figure for all theſe three plants, they are all ſo like that it were needleſſe to multiply more figures, the place and the dented leaves making the whole difference.

2 *Virga aurea ſerratis folijs.*
Golden Rod with dented leaves.

The

The Place.

The first is as I said frequent enough in divers places of the land, in the open places of woods and copses, both in moist and dry grounds, the second is not so frequent, and is found but in few places, although *Gerard*, deceived with the common kinde, which he found sometimes, to have but a few dents about the edges, thought it to be the other, and therefore said that both sorts were to be found plentifully in *Hampsteed* wood, neere unto the gate that leadeth to *Kentish* Towne, when as all that there groweth, as I said for the most part, is but of the first sort, yet in some places it is there to be found also, but more sparingly. The last as I said before, came from *America*, but from what part I know not.

The Time.

The first flowreth later then the second, which is about *July*, and the other in the beginning or middle of *August*. The last also flowreth very late.

The Names.

The first is generally called by all writers almost, *Virga aurea*, because the stalkes being reddish, make the bushy toppes of flowers seeme as if they were of a gold yellow. The second is called *foliis non serratis* by *Camerarius* in his Epitome of *Matthiolus*, or *major angustifolia*, as he doth in *horto*, *Lobel* in *Adversaria*, giveth the title of *Virga aurea Villanovani*, but his description is of the other, (for in his *Icones* and observations, he called that which is not dented about the edges *Virga aurea Villanovani*, and the other *altera serrato folio*) *Anguillara* thought it might be the *Leucographis* of *Pliny*, because it is said in the description thereof, it is found sometimes with white strakes in the leaves, but why *Tabermontanus* should take it to be *Symphitum petræum*, is not well knowne, for he maketh three sorts, whereof this is his third, and the other two be the other *serratis foliis*, whereof he found or saw one, with somewhat rounder leaves, and whose flowers were more white then the others. The last hath his name in his title, as is fittest for it. It is called in *French Verge d'or*, and in high and low *Dutch gulden roede*, and we in *English* Golden Rod.

The Vertues.

As Golden Rodde is like unto the Sataſins Consound in forme, but much lesser, so is it also in the properties, not much inferiour, being hot and dry almost in the second degree. *Arnoldus de villa nova*, commendeth it much against the stone in the reines and kidneyes, and to provoke urine in abundance, whereby the gravell or stone engendred in the uritory parts, by raw and tough flegmatike humours, may be washed downe into the bladder, from growing into a stone in those parts, and thence may be avoided with the urine: the decoction of the herbe greene or dry, or the distilled water thereof is very effectuall for inward bruises, as also to be outwardly applyed: the same also stayeth the bleedings in any part of the body, and of wounds also, and the fluxes of the menstruall courses in women, and the fluxes of the belly and humours, as also the blooddy flixe in man or woman: it is no lesse prevalent in all ruptures, or burstings, to be both drunke and outwardly applyed: it is the most soveraigne woundherbe of many, and can doe as much therein as any, both inwardly for wounds and hurts in the body, and for either greene wounds, quickly to cure them, or old sores and ulcers, that are hardly to be cured, which often come by the fluxe of moist humours thereunto, and hinder them from healing: it is likewise of especiall use in all lotions for sores or ulcers in the mouth, and throate, or in the privy parts, of man or woman: the decoction thereof likewise helpeth to fasten the teeth that are loose in the gummes.

CHAP. XXXIII.

Lysimachia. Loosestrife or Willow herbe.

INtending next unto the Golden rods, to shew you the sorts of Loosestrife or Willow herbe, I am forced for methods sake, and that I might not encumber your memory, with too many in one Chapter, to divide them, and speake of them severally; those with yellow flowers first; and secondly, of those that doe not beare their flowers in spiked heads: thirdly, of them that doe beare spiked flowers: and lastly of those that doe beare their seede in longs huskes, or pods, bee they wilde in our owne land or in others, and brought into gardens.

1. *Lysimachia lutea major vulgaris.* Common yellow Loosestrife or Willow herbe.

The greater yellow Loosestrife, or Willow herbe, which is the more common, groweth in ranke moist grounds, to be foure or five foote high, or more, with great round stalkes, a little crested, diversly branched, from the middle of them to the toppes, into great and long branches, on all which at the joynts there grow, long and narrow leaves, but greater and broader below, most usually two at a joint, yet sometimes three or foure, somewhat like unto Willow leaves, without nickes or dents on the edges, and of a faint greene colour, from the upper joynts of the branches, and at the toppes of them also stand many yellow flowers, of five leaves apeece with divers yellow threds in the middle, which turne into small round heads, wherein are contained small cornered seede, the roote creepeth underground; almost like Couchgrasse, but greater, and shooteth up every spring browniſh heads, which afterwards grow up into stalkes, &c. it hath no sent or taste, but onely astringent and thereby drying.

2. *Lysimachia lutea minor.* The lesser yellow Willow herbe.

This yellow Willow herbe, or Loosestrife, as it riseth not up so high as the former, with his round joynted stalkes, which are somewhat woolly or hairy, so the leaves being also woolly and somewhat like them, are narrower and shorter then they, foure for the most part, and sometimes but three set together at a joint, spotted with blackish spots, on the underside of them, not compassing it at the bottome, but every one standing upon a short footestalke, and not dented about the edges at all, from the middle of the stalke almost, upwards at every joynt commeth forth the branches, which are short, nothing so long as the former, and standing closer together, whereon grow a few leaves, lesser then those below; at whose toppes, and at some of the upper joynts also, stand a few flowers lesser then the former, but yellow, and consisting of five leaves as they are, with many yellow threds in them, of a strong sweete sent, which so joyne together at the bottome, that the whole flower

1. *Lysimachia lutea major vulgaris.*
Common yellow Loosestrife or Willow herbe.

3. *Lysimachia lutea flore globoso.*
Roundheaded yellow Willow herbe.

falleth away together, and not any leafe apart, the roote creepeth under the ground, and shooteth up againe in the same manner, this hath a little more acrimony in it then the other, causing one to spit after the chewing thereof, a while in the mouth.

3. *Lysimachia lutea flore globoso.* Round headed yellow Willow herbe.

The stalkes of this Willow herbe rise not up to be above a foote high, bearing onely two leaves and no more at a joynt, which are shorter and narrower, yet very like unto those of the common sort, and of a pale greene colour, at the joynts of the stalkes, which are crested and hollow, with the leaves come forth long stalkes of flowers, without any leaves on them, which are close set together, almost round, but yet shewing the small yellow flowers, of five leaves a peece, the rootes are long, creeping underground, with many joynts therein, and shooting fibres at every one of them.

The Place.

The first groweth in many places of the land, in moist medowes and by water sides. The second groweth also neere water sides, and in the valleyes, and moist fields of the *Alps*, and hils in *Austria*, as *Clusius* saith. The last as *Lobel* saith; he found in the ditches neere *Gaunt* in *Flanders*, as also among the reedes, wherewith they thatch their houses, hard by *Amsterdam* in *Holland*, and *Clusius* saith it was found by a Physitian neere the *Alps*, who sent it unto him among other plants.

The Time.

All these sorts doe flower from *Iune* unto *August*.

The Names.

It is called in Greeke Λυσιμάχιον & Λυσιμάχον. *Lysimachium*, and *Lysimachia* by divers in Latine, it is thought by divers that this is that herbe, whereof *Pliny* saith *Lysimachus* the King of *Illyria* was the first finder, and of him tooke the name *Lysimachia*, but therein they are deceived, for *Pliny* attributeth a purple flower thereto, and is therefore the *Lysimachia purpurea spicata*, hereafter described, which is made famous by *Erasistratus*, who wrote a volume of the properties thereof, and so saith *Pliny*, and is also supposed to have taken the name, *a pugna dirimenda* for λύειν τὴν μαχὴν, *est certamen dirimere*, of taking away strife or debate betweene beasts, not onely those that are yoked together, but even those that are wilde also, by making them tame and quiet, which as they say this herbe will doe, if it be either put about their yokes, or their neckes, which how true I leave to them shall try, and finde it so. This is called also in Latine *Salicaria*, *aut quod inter Salices oritur*, *aut quod Salicis folio habet*, that is Willow herbe, either becaus it groweth among Willows, or that it hath Willow like leaves. *Leonicerus* saith it was called by divers in his time *Corneola*, and that they dyed a greene colour therewith. The first is called by all writers, either *Lysimachia lutea & vera*; by *Cordus in Dioscoridem*, or *Lysimachium verum, & Legitimum*, becaus it is the same of *Dioscorides*. *Tragus* onely, and *Gesner in hortis* call it *Salicaria*, *Bauhinus* calleth it *Lysimachia lutea major*, *quæ est Dioscoridis*, The second is called by *Clusius*, *Lysimachia lutea altera*, by *Cæsalpinus* *Lysimachia lutea in alis foliorum florens*, and by *Bauhinus* *Lysimachia lutea minor foliis nigris punctis notatis*.

notatis. The laſt is called by *Lobel*, *Lyſimachia lutea altera*: by *Cluſius* *Lyſimachia lutea tertia ſive minor*: by *Dodoneus* in his *Dutch* Herball, *Lyſimachium aquatile*: by *Bauhinus* *Lyſimachia latifolia flore globoſo luteo*. *Dodoneus* ſheweth that *Ruellius* erred, in thinking that *Lyſimachia*, was the *Lutea herba*. It is called of the *Italians* *Lyſimachis*: of the *Spaniards* *Lyſimacho*: of the *French*, as *Ruellius* ſaith, *Cornolle* and *Corneolle*, as alſo *Souſsy d'eau*, *Perce boſſe*, and *Pelle boſſe*, *ideſt*, *Peſti fuga*; but *Dodoneus* contradicteth *Ruellius* therein, ſaying that *Pelleboſſe*, with thoſe of *Cenomania*, is another herbe, even the *Ranunculus flammeus*, which will raiſe bliſters upon the skinne, and will draw the venome of a Plague ſore another way: of the *Germaines* *Widerich* and *Geilweyderick*: of the *Dutch* *Geel Wederijck*: and in *Engliſh* Willow herbe, and Looſeſtrife.

The Vertues.

Galen ſaith that this Willow hearbe, hath an exceeding binding quality, and therefore *Dioſcorides* ſaith, it is good to ſtay all manner of bleedings at the mouth or noſe, or of wounds, or howſoever, and all fluxes of the belly, and the bloudy flix, given either to drinke, or taken by gliſter; it ſtayeth alſo the aboundance of womens courſes: it is a ſingular good herbe for greene wounds, to ſtay the bleeding, and quickly to ſoder, or cloſe together the lippes of the wound, if the juyce of the herbe onely be bruiſed and applyed: it is often uſed in gargles for ſore mouthes, as alſo for the ſecret parts: it is found very certaine by good experience, that the ſmoake hereof being burned, driveth away flies and gnats, and other ſuch like ſmall creatures, which uſe in diverſe places, that are neere to Fennes, Marſhes, or water ſides, to infeſt them that dwell there, in the night ſeaſon to ſting and bite them, leaving the markes and ſpots thereof in their faces, &c. which beſides the deformity, which is but for a while, leaveth them that are thus bitten, not without paine for a time: it is ſayd alſo to drive away Serpents, or any other venemous creature, by the ſmoake of the hearbe burned.

CHAP. XXXIIII.

Lyſimachia non ſpicata. Willow herbe, with diſperſed heads of flowers.

THe ſecond ſort of Looſeſtrife is of thoſe whoſe flowers ſtand not in ſpiked heads, but diſperſedly upon the ſtalkes, whereof there is two ſorts onely to be remembred in this Chapter.

1. *Lyſimachia minor rubra ſive purpurea.* Small red flowred Willow herbe.

This ſmall Willow herbe or Looſeſtrife, is much lower than that of the purple ſpiked head, being but a foote and a halfe high, with ſmooth and ſquare ſtalkes, whoſe toppes are parted into many branches; on the lower part thereof ſtand long leaves, ſmaller and narrower than the other purple ſpiked kinde; two alwayes ſet together at a joynt, one againſt another: but thoſe that grow above toward the toppes of the ſtalkes, are ſmaller than the lowermoſt, and keepe not that order, but ſtand confuſedly thereon one above anothor, neere unto which, at the joynts with the leaves, come forth ſeverall flowers, but not ſpike faſhion, in ſixe ſquare heads uſually whoſe toppes are not ſo pointed, nor layd ſo open as in the other, but being more cloſe, thruſt forth their flowers out of them, which conſiſt of ſixe ſmall reddiſh purple leaves, with ſome threds in the middle: the roote creepeth not as the others doe, but is hard and ſomewhat wooddy, with many ſmall fibres, getting encreaſe from the ſides thereof.

1. *Lyſimachia purpurea ſive rubra minor.*
The ſmall purple flowred Willow herbe.

2. *Lyſimachia purpurea ſive rubra minima.* The leaſt purple flowred Looſeſtrife.

This other Looſeſtrife, being the leaſt, riſeth up ſcarce a foote high, the ſtalkes branch themſelves forth, from the very botrome; ſet thicke with ſmall, long, and narrow leaves, almoſt like thoſe of Line or Flaxe, but ſhorter; with whom at the joynts come forth the flowers, ſometimes two at a place, but more uſually one, ſtanding in greene huskes, like unto the laſt; compoſed of five ſmall blewiſh purple leaves, enclining to red; in which huskes after the flowers are fallen, ſtand ſmall skinnie heads, wherein is conteined ſmall whitiſh ſeede, the roote is ſmall, long, and browne. Vnto this ſort might belong, according to ſome mens opinion, the *Lyſimachia cærulea galericulata*, which I have already ſet forth in the Chapter of *Gratiola*, as a ſort of that kinde, in the Claſſis of purging plants; but as I there ſayd, there was the fitteſt place for it in my judgment; both for that it is extreame bitter, and hath hooded flowers, both which are proper to the *Gratiola*, and not to the *Lyſimachia*, none of them being ſo: as alſo that diverſe of good judgement have likewiſe called it *Gratiola cærulea*.

The Place.

The firſt groweth in moyſt Meddowes, and grounds nigh unto water courſes, in many places of *Hungary*, as *Cluſius* ſaith, the other he ſaith alſo he had of Doctor *Mera*, who gathered it in ſome places (not named) in his returne out of *Italy* into *Germany*.

The Time.

They flower in *Iune* and *Iuly* with the rest.

The Names.

The first *Clusius* calleth *Lysimachia purpurea secunda sive minor*: and by *Bauhinus*, *Lysimachia rubra non siliquosa*: the other *Clusius* likewise calleth, *Lysimachia rubra minima*: and *Bauhinus Lysimachia Lini folia purpurea cærulea.*

The Vertues.

It is no doubt but these herbes, being so like in face and outward forme unto the *Lysimachia*, are not onely to be accounted as *species* thereof, but of the same property in some measure with them, but thereof I know not any tryall made, and therefore can say no more of them.

CHAP. XXXV.

Lysimachia spicata. Loosestirfe with spiked heads of flowers.

THere are likewise two sorts of this kinde of *Lysimachia*, to be entreated of in this Chapter, which are as followeth.

1. *Lysimachia spicata purpurea.* Purple spiked headed Loosestrife.

This Willow herbe or Loosestrife, that carryeth a spiked head of flowers, groweth with many wooddy square stalkes, full of joynts, about three foote high at the least, at every one whereof stand two long leaves, not altogether so great and large as those of the common yellow, but shorter, narrower, and of a deeper greene colour, and some browniſh: the stalkes are branched into many long stemmes of spiked flowers, halfe a foote long; growing in rondles one above another, out of small huskes, very like unto the spiked heads of Lavander; each of which flowers have five round pointed leaves, of a purple violet colour, or somewhat enclining to redneſſe; in which huskes stand small round heads, after the flowers are fallen, wherein is conteined small seede: the roote creepeth under ground like unto the yellow, but is greater than it, and so are the heads of leaves, when they first appeare out of the ground, and are more browne than those of the yellow.

Lysimachia Virginiana flore carneo. Blush Willow herbe of *Virginia.*

This Willow herbe hath many faire long and large leaves, &c. expect the rest hereafter.

2. *Lysimiachia spicata cærulea.* Blew spiked Loosestrife.

This blue flowred Loosestrife, groweth somewhat lower, with some branches in the like manner at the toppes of the square stalkes, and with darke greene and narrower leaves, set by couples at the joynts towards the

1. *Lysimachia purpurea spicata.*
Purple spike headed Looseſtrife.

2. *Lysimachia cæru'ea spicata.*
Blue spiked Looseſtrife.

toppes

toppes; but with three or foure at a joynt lower, somewhat deepelyer snipped or dented about the edges: the flowers grow in the same manner as the former doe, in long spiked heads, set round about with blue flowers, of foure leaves a peece, which turne into small flat heads with browniſh seede therein: the roote creepeth not as the first doth, but shooteth forth many sprouts round about it, whereby it doth much encrease.

The Place.

The former groweth usually by rivers, and ditches sides, in wet grounds; as upon *Lambeth* side about the ditches there, in many places: the other is seldome found in our Land, but in *Austria*, and other places of *Germany* plentifully.

The Time.

Both these doe flower in the monthes of *Iune* and *Iuly*.

The Names.

The formost is certainely the *Lysimachia* that *Plynie* remembreth, and to take the name from *Lysimachus*, as is before sayd, and is the *Lysimachia altera* of *Matthiolus*, the *Lysimachia Pliniana* or *purpurea* of *Lobel* in his *Adversaria* and Observations; the *Lysimachia purpurea communis major*, of *Clusius*; the *Pseudo Lysimachium purpureum alterum* of *Dodonæus*; and the *Solidaginis Saraſenicæ alia ſpecies* of *Tragus*: there have beene some that have taken it for *Eupatorium*, and some for a kinde of *Centaurium*, but they have erred both: the other is taken by some, to be *Veronica recta major*, but others and that more truely make it a *Lysimachia*; as *Clusius*, who calleth it *Lysimachia cæruleo flore*; *Lobel Lysimachia cærulea hortensis*; *Lugdunensis* and *Dodonæus*, who calleth it *Pseudo lysimachium cæruleum*, and saith that many *Dutch* did call it *Partiicke*. *Bauhinus* calleth it *Lysimachia ſpicata cærulea*; whom I thinke to be of as good and sound judgement, as any other, whom I doe follow as you see.

The Vertues.

The properties of these hearbes, being cooling and drying, are to be referred to the former, wherein they scarse come behind the best of them, and therefore it needeth not that I should make a repetition of the same things againe, seeing any man may safely use the one in stead of the other, when it is not neere at hand, or to be gotten. And more by particular experience this hereafter hath beene found, and by a friend imparted, of whose learning and judgement there needeth no question: The destilled water is a present remedy for hurts and blowes on the eyes, and for blindnesse, so as the christaline humor, or sight it selfe of them be not perished or hurt, or be not spoyled; which experiments was found true, upon a boy, whose eye by chance was pricked, and restored hereby; as also by another who being hurt in the eye, athwart by a dart, was cured onely by applying this water outwardly: he that performed this cure, and the like upon divers, would not declare this secret to any; and therefore the Physitions and Chirurgions, that undertooke to cure another hurt in the same manner, and refusing this water, failed of their cure, and left him blind that they dealt with. It is of as good use to cleere the eyes of any dust, or other thing gotten into the eyes, and keepeth the sight from much danger. It is also availeable against wounds and thrusts; to be made into an oyntment with *May* butter, waxe, and sugar, in this manner. Take to every ounce of the water, two drammes of *May* butter without salt, and of sugar and waxe of each as much also, let them boyle gently altogether; let tents be dipped in the liquor that remaineth after it is cold, and put into the wounds, and the place covered with a linnen cloath, doubled and annointed with the oyntment: this was proved on a Captaine, who was shot in two places with bullets, the one through his breast, the other through his thigh, and was perfectly cured of both wounds without any scarre, onely by applying them as aforesayd, when as he could not be holpen by other remedies applyed. It likewise clenseth and healeth all foule ulcers and sores wheresoever, and stayeth their inflammations, by washing them with the water, and laying on them a greene leafe or two in summer, or dry leaves in winter. This water gargled warme in the mouth, and sometimes drunke also, doth cure the Quinsie, and Kings Evill in the throate: The sayd water applyed warme taketh away all spots, or markes and scarres in the skinne, which are caused by the Measells small Poxe or the like. And lastly, if one drinke of this water, when they are very thirsty, or in any journey not having any drink, it will presently slake their thirst.

CHAP. XXXVI.

Lysimachia siliquosa. Codded Looseſtrife.

THE last kinde of Looseſtrife to be spoken off, is those that beare their seedes in cods, whereof there are divers, one kind hereof under the name of *Chamænerium flore delphinij*, Willow flower, and the *Virginian* Looseſtrife, belongeth to this place; which although I have set them forth in my former Book, and wil not describe them againe, yet I wil here give you the figure of the *Virginian*.

1, *Lysimachia siliquosa angustifolia Chamænerium Gesneri dicta*,
The narrow leafed codded Looseſtrife.

This codded Looseſtrife (I place first of this kinde, as most worthy in my judgement, both for the rarity, beauty and property) riseth up with divers hard stalkes, about two and sometimes three foote high, with many very narrow long greene leaves thereon, somewhat like unto Rosemary leaves in my opinion, set very thicke with two at a joynt, those below, being shorter then those up higher, at the toppes of the stalkes come forth many flowers, made of foure small round pointed leaves, of a fine reddish colour, and some threds in the middle, every one standing on the toppe of a small long almost square codde, whitish on the outside, and stuffed with fine cotton or downe, wherein lye bright red seedes, which cods with seedes therein appeare, before the flowers doe breake forth at the ends of them, whereupon some have called it *Filius ante patrem*, the roote creepeth in the same manner that the yellow and blew doe. Of this kinde both *Gesnerus*, *Thalius*, and *Clusius* say, they found one with white flowers, not differing in any thing else from the other. *Flore Albo*

2, *Lysimachia Chamænerium dicta Alpina*. The mountaine codded Looseſtrife.

This mountaine Looseſtrife hath very short stalkes, seldome more then a foote high, whereon grow very narrow,

narrow leaves, like unto the former, yet some longer then others set without order: for the smaller come sometimes from the middle of the longer, and sometimes stand at the joynts; at the toppes of the stalkes stand the flowers upon slender long purplish stalkes, and sometimes whitish, of a purplish or reddish blew colour, and in some of a whitish blew colour, consisting of foure reasonable great leaves, even as great as the former, which the smallnes of the plant doth scarse admit, with some threds in the middle, every one of them standing in a small huske, composed of foure short greene leaves, wherein after the flowers are falne, grow up small ong pods, with smal seed in them, enclosed in downe like the other, the roote hereof creepeth not, but is composed of many fibres, which whether it be annuall or longer abiding, I have not yet learned.

1. *Lysimachia siliquosa angustifolia Chamæneriam Gesneri dicta.*
The narrow leafed codded Looseſtrife.

3. *Lysimachia siliquosa major.*
The greater codded Looseſtrife.

This greater Looseſtrife shooteth forth divers round greene stalkes, three foote high at the least, bearing thereon at the severall joynts, two leaves a peece, which are somewhat like the common yellow Looseſtrife, but smaller and smoother, greene on the upper side, and of a yellowish greene underneath, and dented about the edges, the stalkes send out from the middle upwards many branches, at the toppes whereof grow many small long pods, of a whitish greene purple colour, wherein the reddish seede lying in downe is contained, and at the end of them after they have appeared a good while; come forth the flowers made of foure round pointed leaves a peece, with some threds in the middle, of a faint reddish or purplish colour, the roote is somewhat great and white, creeping every way underground, and quickly possessing a good plat of ground, which abide in the winter, although the stalkes dye downe every yeare. Of this sort likewise there hath beene one found with white flowers, but very seldome and rare.

Flore albo.

4. *Lysimachia siliquosa minor vulgaris sylvestris.*
The wilde lesser codded Looseſtrife.

This lesser sort that groweth wilde in divers places, riseth up scarse two foote high, and in some places, not a-

6. *Lysimachia siliquosa Virginiana.* Codded Looseſtrife of *Virginia*, or tree Primrose of *Virginia*.

bove

bove a foote high, with ſmaller ſtalkes and narrower leaves, not ſo greene, but rather of a grayiſh duſty greene colour, and hath many branches, bearing his flowers of foure leaves a peece, at the ends of long pods, of a deeper red colour, as the former doth, and hath like ſeede in downe but ſmaller: the roote is ſmall and fibrous, dying every yeare.

5. *Lyſimachia ſiliquoſa ſylveſtris hirſuta.* Hairy wilde codded Looſeſtrife.

This other is in growing, and height in leaves and flowers, and yearely dying like unto the laſt deſcribed, the onely difference betweene them is, that the leaves are more hairy, and as it were woolly, and the flowers alſo ſmall and paler.

6. *Lyſimachia ſiliquoſa Virginiana.* Codded Looſeſtrife of *Virginia.*

This is ſet forth in my former Booke, and ſo is *Chamænerium Geſneri.*

The Place.

The firſt groweth more often in moiſt grounds then in dry, yet *Geſner* and others ſay, it doth grow in thoſe places that are open to the Sunne all day; it will hardly abide in our Gardens, unleſſe it be planted in ſome ſhadowy place. The ſecond groweth upon the *Alpes*, in the Country of the *Switzers*. The third groweth in divers moiſt places, and is often found of it ſelfe in Gardens, alwaies delighting where it may be kept moiſt by ſhadowing, the other ſorts grow wilde in dry grounds, as by the wayes, and lanes, and borders of fields.

The Time.

They doe all flower in *Iune* and *July*, and are quite paſt in *Auguſt* for the moſt part.

The Names.

They are all called *Lyſimachia ſiliquoſa* from the long cods they beare, which none of the others have, the formoſt are alſo called *Chamænerium* by *Geſner*, but in my minde that name doth more fitly ſerve to the other ſort hereof, which we call the Willow flower, ſet forth in my former Booke, by the name of *Chamænerium flore delphinij*, for that hath long greene leaves, very like unto Peach leaves, or the leaves of *Nerium*, or *Oleander* the Roſe bay, whereas this as I ſaid, hath narrow leaves like Roſemary, and *Geſner* himſelfe doth not well like of the name *Chamænerium*, but rather calleth it ἐπιλόβιον *Epilobium*, a word made of three, that is ἰὸν ἐπὶ λοβοῦ, *quia viola, id eſt flos, ſuper ſiliqua naſcitur*, and reckoneth up ſixe ſorts thereof, as he ſetteth them downe, at the end of *Cordus* his Hiſtory of Plants. *Dodonæus* and *Lobel* have ſet this forth as a ſmaller kinde of the greater wilde ſort, which is the third here ſet downe. And *Bauhinus* calleth it *Lyſimachia latifolia*, and this *Anguſtifolia*, as they ought to be. *Lugdunenſis* expreſſeth it under the name of *Linaria rubra*. *Dodonæus* calleth it *Pſeudo Lyſimachium purpureum minus*, for as I ſaid before, he maketh the third ſort here to be the *majus*. The reſt neede no further amplification, being every one is expreſſed in their title anſwerable unto them, and not much varying from what others call them; onely *Cæſalpinus* calleth the third ſort, *Onagræ genus alterum*, for hee calleth the *Chamænerium flore Delphinij*, *Onagra*.

The Vertues.

The firſt which is more uſed in phiſicke then any of the reſt, is hot and dry in the ſecond degree, as *Geſner* ſaith, and very aſtringent withall, and ſomewhat abſterſive, whereby it conſiſteth of divers parts, but is effectuall both to ſtanch blood, reſtraine fluxes, heale the ſores of the mouth and ſecret parts, cloſe up quickly greene wounds and heale old ulcers, and briefely doe and performe almoſt as much as the ordinary *Lyſimachia* can.

CHAP. XXXVII.

Veronica mas. The male Speedewell.

OF the Speedewels there are two kindes, the male and the female, of the male there are many ſorts, which ſhall be ſet forth in this Chapter, and the female in the next.

1. *Veronica mas vulgaris ſupina.* The common Speedewell.

The common Speedewell hath divers ſoft leaves, of an hoary greene colour, a little dented about the edges, and ſomewhat hairy alſo, ſet by couples at the joynts of the hairy browniſh ſtalkes, which leane downe to the ground, never ſtanding upright, but ſhooting forth rootes as they lye upon the ground at divers joynts, the flowers grow one above another at the toppes, being of a blewiſh purple colour, and ſometimes it is found white, after which come ſmall flat huskes, wherein is ſmall blackiſh ſeede included, the roote is made of many fibres.

2. *Veronica mas erecta.* Vpright Speedewell.

This Speedewell differeth from the former in this, that the ſtalkes leane not downe to the ground, but ſtand more upright, having ſomewhat narrower and greener leaves then the other, and the flowers ſtand thicker together, as it were in a ſpike, of a faint blew colour, and the roote creepeth under ground. There is a leſſer ſort hereof, differing onely in the lowneſſe, and in the ſmallneſſe both of leaves and flowers. *Minor.*

3. *Veronica ſpicata latifolia major.* The greater ſpike flowred Speedewell.

This greater ſpiked Speedewell, riſeth up with divers creſted ſtalkes full of joynts, two foote high, whereon ſtand two large, ſhining, thicke, and darke greene leaves, and in ſome neither ſhining nor ſo darke, ſomewhat dented about the edges, the ſtalkes have very ſeldome any branches, but have ſometimes two or three ſtalkes of ſpiked flowers, ſomewhat larger then the laſt, and of the ſame pale blew colour, flowring by degrees the loweſt firſt, the ſeede that followeth is ſmall, encloſed in ſmall flat huskes as the other, the roote is ſomewhat blacke and fibrous, encreaſing by the ſides.

4. *Veronica erecta anguſtifolia.* Spiked Speedwell with narrow leaves.

This upright Speedewell hath his ſtalkes about two foote high, ſet at the joynts with two leaves a peece, which are longer and narrower then the laſt, and ſlightly dented about the edges, of a bitter and unpleaſant taſte, on the toppes of the ſtalkes, which are as ſeldome branched as the laſt, ſtand the flowers in long ſpiked heads, many ſet together, every one having foure pale blew leaves a peece, with ſome threds in the middle, which after they are paſt give ſmall ſeede veſſels, which are flat, but a little ſwelling in the middle, and bicornered at the head,

1. *Veronica mas vulgaris supina.*
The common Speedewell.

2. *Veronica mas erecta.*
Vpright Speedewell.

3. *Veronica spicata latifolia major.*
The greater Spikeflowred Speedewell.

4. *Veronica vella angustifolia.*
Spiked Speedewell with narrow leaves.

head, wherein lye very ſmall browniſh ſeede; the roote creepeth in the ground and ſhooteth forth many fibres.

5. *Veronica pratenſis minor.*
Small medow Speedewell.

The ſmall medow Speedewell, hath many leaves, ſmaller, greener, ſmoother, and rounder then any of the former, growing by couples on the divers ſpreading ſtalkes, and at the toppe, divers ſmall blew flowers like the laſt, and ſo is the ſeede likewiſe, the roote creepeth in the ſame manner.

6. *Veronica minima Bellidis folio.*
The leaſt Speedewell with Daiſie leaves.

This Speedewell groweth not an handbredth high, with an hard hairy flexible ſtalke, bending downe to the groundward, at the foote whereof are many hairy leaves, ſmall, thicke, ſomewhat round pointed, and of a darke greene colour, very like unto the Blew Daiſie leaves, but on the ſtalke it hath but few, two ſtanding alwayes at a joynt, one oppoſite to the other, the flowers are blew, of foure and ſometimes of five leaves a peece; with a pointell and two threds in the middle, the ſeed veſſels that follow are flat and ſhort, bearing a pointell in the middle, and containe ſuch like ſmall browniſh ſeede, the roote creepeth about, and encreaſeth quickly.

7. *Veronica fruticans.*
Shrubby Speedewell.

Shrubby Speedewell hath many wooddy flexible branches, a foote high or more, lying upon the ground, and taking roote as they lye, full of joynts, whereat ſtand two long thicke greene ſhining leaves, dented about the edges, one againſt another, at the joynts with the leaves on each ſide of the ſtalke, ariſe long greene branches, with ſuch like leaves on them, at the toppes whereof ſtand ſixe or ſeaven flowers, one above another conſiſting of foure and ſometimes of five leaves, of a very dainty blew colour, and more pale in the middle, circled about with a red ring, having in the middle a long ſtile or pointell, and two

7. *Veronica fruticans.*
Shrubby Speedewell.

8. *Veronica minor Alpina.*
Small mountaine Speedewell.

9. *Veronica Teucrij facie.*
Germander like Speedewell.

ſmall

ſmall long threds, after which come the ſeede veſſels, being greater then any of the reſt, flatter alſo and broader, wherein the ſeede lyeth, being flat, yellowiſh, and ſmall, the roote is long and wooddy, with many fibres thereat.

8. *Veronica Alpina minor.* Small mountaine Speedewell.

This ſmall Speedewell from a ſmall hard and threddy roote, ſhooteth forth ſundry ſtalkes with ſmall leaves thereon by couples, ſomewhat larger then Mother of Time leaves, ſeldome dented about the edges, and of a darke greene colour, the flowers are ſmall and of a pale blew colour, ſtanding without order at the toppes of them, ſometimes conſiſting of foure, and ſometimes of five or ſixe leaves apeece, the ſeede that followeth, is ſmall round and blacke, and abideth with greene leaves thereon all the Winter.

9. *Veronica Teucrij facie.* Germanderlike Speedewell.

This Speedewell hath ſquare rough ſtalkes about a foote high, with long narrow dented leaves, ſet by couples at the joynts, the toppes ending in a long ſpiked head of foure leafed blew flowers and ſeede ſucceeding like the greater Speedewels.

The place.

The firſt groweth in all Countries of this land, upon dry bankes and wood ſides, and other waſte ſandy grounds, eſpecially. The ſecond groweth in *Auſtria* and other parts of *Germany*. The third and fourth grow, as well on the mountaines of *Hungary*, as in the vallies at the foote of the *Alpes* in *Auſtria*, *Stiria*, *&c.* The fifth groweth in ſome places of this Land, as well as beyond the Sea. The ſixth *Cluſius* ſaith he found on the hill in *Stiria*, called *Sneberg*, whereon Snow lyeth almoſt all the yeare through. The ſeventh was found on the *Pyrenian* hils, by Doctor *Burſerus*, who brought it to *Bauhinus*. The eighth, and the laſt on Mount *Baldus*.

The Time.

They flower in *Iune* and *Iuly*, and their ſeede is ripe in *Auguſt*.

The Names.

It hath no Greeke name that I know, being not knowne to the ancient writers, *Dodonæus* onely taketh it to be the other *Betonica Pauli Æginetæ*, which he ſaith is like unto Penniroyall, but not that is called Κέστρον, wherby the Greekes call the true and right Betony, and thereupon this is very ordinarily called of many, *Betonica Pauli*, or *Veronica mas*, and *ſupina*, to diſtinguiſh it from the other. *Tragus* in his time tooke it to be *Teucrium*, and many learned men doe likewiſe referre moſt of the other ſorts thereunto. The ſecond ordinary upright ſort, is called by *Cæſalpinus Auricula muris tertia*, as the *ſpicata* is his fourth, and the fifth here, his *prima*, which *Dodonæus* calleth *pratenſis*, *Tragus Teucrium alterum*, and *Brunfelſius Eufragia nobilis*, but *Lobel* in his *Adverſaria Veronica minor ſerpillifolia*. *Dodonæus* in his *French* Herball calleth this *fœmina*, and ſo did *Tabermontanus*, but by the judgement of the beſt Herbariſts of our times, all theſe ſorts are *ſpecies* of the male kind, the female being another herbe of a differing forme, as you ſhall preſently underſtand, *Gerard* hath foully erred not onely in the figure, but in the deſcription alſo of his ſecond *Veronica*, which is called *recta*, not onely in ſaying that it creepeth contrary to the very title, but in the flowers alſo, ſaying they are yellow. All the reſt have their names in their titles, as proper to them by moſt other authours, and therefore I ſhall not neede a further explanation of them. The *Italians* call it *Veronica maſchio*. The *Germanes Grundheyl*, and *Ehrenpreiſſ. i. e. laudata nobilium*, that is to ſay, honour and praiſe, and ſo the *Dutch* as *Lobel* ſaith call it. In *Engliſh* Speedewell, and *Paules* Betony, and of ſome *Fluellen*, which being a *Welch* name, is more proper I thinke to the female kinde, whereof they give admirable praiſes.

The Vertues.

The male Speedwell is temperately hot and dry, the bitterneſſe thereof ſhewing it, and is held a ſingular good remedy for the Plague, and all Peſtilentiall Fevers, and infectious diſeaſes, to expell the venome and poyſon from the heart, and afterwards to corroborate and ſtrengthen it, from noyſome vapours, if the pouder of the hearbe to the quantity of a dramme or two, be given with a dramme of good Treacle, in a ſmall draught of wine, and they be layd to ſweate: the decoction of the herbe in wine, or the diſtilled water thereof, given in ſome wine, performeth the ſame thing: it is reported that a *French* King troubled with the Leproſie, was cured thereof by this hearbe, one of his huntſmen adviſing him thereunto; it doth alſo wonderfully helpe the memory, and to eaſe all turnings and ſwimmings, and other paines of the head, and as it is ſayd helpeth women to become fruitfull, that were barren: it clenſeth the blood from corruption: the decoction of the hearbe in water, or the powder thereof dryed, and given in it owne diſtilled water, is ſingular good for all manner of coughes and diſeaſes of the breſt and lunges, by the warming and drying quality; which thing the Shepheards have ſufficiently tryed, who give their ſheepe that are troubled with the cough, or the like, ſome of this hearbe, and a little ſalt with it: it openeth the obſtructions of the liver, and is therefore good for the yellow Iaundiſe: it openeth alſo the obſtructions of the ſpleene, being taken for ſome time together inwardly, or the herbe bruiſed and applyed with ſome Vinegar to the region of the ſpleene outwardly; it clenſeth the exulcerations of the reines and bladder, or of the mother alſo, or any other inward wounds or ſores: it provoketh Vrine, and helpeth thereby to breake the ſtone, and as *Paulus Ægineta* ſaith, is of much good uſe in all medecines for the backe and reines: it it is ſingular good to heale all freſh wounds, and cuts in the fleſh, ſpeedily cloſing the lippes of them together, and not ſuffering them to gather corruption: it is no leſſe effectuall alſo for ſpreading tetters, and for foule or old frettings, or running ſores or ulcers, that are of hard curation, or are of long continuance: it ſtayeth the bleedings of wounds or other fluxes of blood in any otherpart, and diſſolveth all tumors and ſwellings eſpecially thoſe in the necke. The diſtilled water of the herbe, either ſimple of it ſelfe, or the hearbe firſt ſteeped in wine for twelve houres at the leaſt, and then diſtilled in an ordinary ſtill, but not in any *Limbecke*, to make it an hot water, as others are after that manner, doth wonderfully helpe, for all the purpoſes aforeſayd, either for the the Plague, the Cough, Conſumptions, &c. and all the other diſeaſes before mentioned, as alſo to waſh wounds and ſores therewith; a little coperas alſo diſſolved in the ſayd diſtilled water, doth wonderfully helpe all itches, ſcabbes and ſcurfe, tetters alſo and the morphew, and all diſcolourings of the skinne, as freckles, ſpots, and markes whatſoever, either riſen from the infection of the blood, and from hot and ſharpe ſalt humours, or the ſcarres that remaine after hurts or bruiſes, if they be bathed therewith: a little alome diſſolved in the ſayd diſtilled water, and ſprinkled upon garments, keepeth them from moths that ſpoyle them.

CHAP.

CHAP. XXXVIII.

Veronica fœmina ſive Elatine. *Fluellen* or the female Speedwell.

OF this *Elatine* there are ſome varieties, obſerved by diverſe, namely two ſorts, but we muſt thereunto adde a third as followeth.

1. *Elatine folio ſubrotundo.* Round leafed Flvellen.

This Fluellen ſhooteth forth, many long branches, partly lying upon the ground, and part ſtanding upright, ſet with almoſt round leaves, yet a little pointed at the ends, and ſometimes more long than round, without order thereon, being ſomewhat hoary, and of an evill greeniſh white colour: at the joynts all along the ſtalkes, and with the leaves come forth ſmall flowers, one at a place, upon a very ſmall ſhort foote ſtalk, gaping ſomewhat like thoſe of Snapdragon, or rather *Linaria* Todeflaxe, whoſe upper jaw is of a yellow colour, and the lower of a purpliſh, with a ſmall heele, or ſpurre behinde, as the *Linaria* hath: after which come ſmall round heads, that containe ſmall blacke ſeede, the roote is ſmall and threddy, dying every yeere, and raiſeth it ſelfe againe of it owne ſowing.

2. *Elatine folio acuminato.* Fluellen with cornered leaves.

This other Fluellen hath longer branches, wholly trayling upon the ground, two or three foote long, and ſometimes more, and more thinnely ſet with leaves thereon, upon ſmall foote ſtalkes, which are a little larger, and ſomewhat round, and cut in or cornered ſometimes in ſome places on the edges, but the lower part of them, being the broadeſt hath on each ſide, a ſmall point, making it ſeeme as if they were eares, ſomewhat hayrie but not hoary, and of a better greene colour than the former: the flowers come forth at the joynts with the leaves, upon little long ſtalkes, every one by it ſelfe, one above another, in forme very like unto the other, but the colours therein are more white, than yellow, and the purple is not ſo faire: it is a larger flower, and ſo are the ſeede and ſeede veſſels: the roote is ſmall and threddy like the other, and periſheth every yeere.

3. *Elatine flore cæruleo folioque acuminato.* Cornered Fluellen with blew flowers.

This third Fluellen differeth little from the laſt, but that the leaves thereon are not ſo much cornered about the edges, and leſſe pointed alſo, at the foote or loweſt part of them, and the flower is almoſt all blew, with a very little whitiſh colour therein.

The Place.

Theſe doe all grow in divers cornefields, and in borders about them, and in other fertile grounds, as about Southfleete in *Kent* aboundantly: at *Buckworth* alſo, *Hamerton* and *Richwerſworth* in *Huntington* ſhire, and divers other places, both there and elſe where.

The Time.

They all likewiſe are in flower about *Iune* and *Iuly*, and the whole plant is dry and withered before *Auguſt* be done.

1. *Elatine folio ſubrotundo.*
Round leafed Fluellen.

2. *Elatine folio acuminato.*
Fluellen with cornered leaves.

The Names.

It is called in Greeke Ἐλατίνη *Elatine*, by the *Arabians Athin*, and by the judgement of the moſt judicious in thoſe latter times, taken to be the true and right herbe that *Dioſcorides*, hath ſet forth by that name, although ſome did ſeeme to doubt of it, as not knowing what *Helxine Dioſcoridis* meaneth, unto whoſe leaves he compareth it, whether unto *Helxine*, which is *Paritaria*, or *Helxine Ciſſampelos*, the blacke Bindweed. *Serapio* ſeemeth to make *Elatine* a kinde of ſmall *Volubilis* or Bindweede, for ſo he compareth it to *Helxine*, which can bee no other than *Ciſſampelos*, but his interpreter *Paulus Ægineta* doth turne *Helexine* to be *Parietaria*. *Ruellius* tooke *Rapiſtrum campeſtre*, the wilde *Charlorke* to be it, for the which *Matthiolus* conteſteth againſt him, as alſo againſt thoſe that would make *Numularia* Monywort, or herbe two pence to be *Elatine*, and againſt others that made *Pimpinella*, *Burnet*, becauſe neither of them were hayrie, nor grew in Corne grounds, as *Dioſcorides* ſaith *Elatine* doth. *Fuſchius* calleth it *Veronica fœmina*, and ſo doth *Matthiolus*, *Lonicerus*, *Camerarius*, *Dodonæus*, and others, and *Lobel* and ſome others *Elatine Dioſcoridis*. *Lugdunenſis* calleth it *Verbaſcum quorundam*, for that ſome in thoſe parts, did it ſhould ſeeme ſo call it, and yet giveth the ſame figure thereof that he gave to *Veronica fœmina Matthioli*. The ſecond is called *Elatine Matthioli* by *Lugdunenſis* and *Caſtor Durantes*, becauſe he firſt ſet forth the figure thereof in his laſt Edition, ſent him as he ſayd from *Cortuſus*, for in his other Editions he knew not this ſort. *Dodonæus* and others call it *Elatine altera*. *Fabius Columna* calleth it *Linaria Hederulæ folio*, becauſe as I ſayd the flowers are ſomewhat like a *Linaria* or Todeflaxe, and the leaves cornered like Ivie: the *Italians*, *French*, *Dutch*, &c. doe all follow the Latine *Veronica fœmina*, and we call it by the name of female Speedwell.

The Vertues.

Although that *Fluellen* be ſomewhat bitter, yet it is held to be more cooling with the drying property, than the former Speedwell. The leaves, ſaith *Dioſcorides* and *Plinye*, bruiſed and applyed with Barly meale, to the eyes that are watering, by defluxions from the head, and that are hot and inflamed withall, doe very much helpe them: it helpeth alſo all other defluxions, as alſo the fluxes of blood, or humours, which are the laske, and bloody flixe, as alſo womens too aboundant courſes, and ſtayeth all manner of bleeding, whether at the noſe, mouth, or any other place, or that commeth by any veine burſt, bruiſed or hurt, wonderfully helping all thoſe inward parts, that neede conſolidating or ſtrengthning, and is no leſſe effectuall, both to heale and cloſe greene wounds, as to clenſe or heale all foule or old Vlcers, fretting or ſpreading Cancres, or the like, as the tryall thereof made upon one can witneſſe; whoſe noſe being almoſt conſumed with a Canker, was (as *Pena* reporteth it) to have his noſe cut off, by the Chirurgians appointed thereunto by the Phyſitians, to preſerve the reſt of the body, ready to fall into a Leproſie, whoſe determination being over heard by a ſimple Barber in company, deſired that he might beforehand, make tryall of an herbe, he had ſeene his Maſter uſe in the like caſe; which being granted, he by uſing the juyce and concoction of this herbe taken inwardly, and the herbe uſed outwardly, recovered the man, who was not onely cured of the danger of his noſe, but of his whole body, and thereby hē was freed from the diſeaſe he was falling into. This occaſion doth make me thinke, that not onely in this herbe, but in many other ſimple herbes, our forefathers found helpe of many diſeaſes, and therefore uſed fewer compounds: and were we in theſe times as induſtrious, to ſearch into the ſecrets of the nature of herbes, as the former ages were, and to make tryall of them, we ſhould no doubt finde the force of ſimples, many times no leſſe effectuall than of compounds: but of this enough, yet not too much, ſo as I might provoke ſome learned to bee more induſtrious, and not like droanes onely to ſucke the honey from others hives: it helpeth alſo all the outward defects of the skinne, when it is diſcoloured, as it is ſayd of the former: for they are both of a faculty very neere in effect, one unto another, and therefore what is ſayd of the one, may very well be applyed to the other.

CHAP. XXXIX.

Numularia. Money-wort, or herbe two pencē.

THere be two ſorts of *Numularia*, onē greater than another, that beare both of them yellow flowers; if that the fertility, or ſterility of the ſoyle doe not cauſe the ſame, which I ſhall ſhew you here, and with them I have another leſſer ſort, with purple flowers, which is alſo found wilde in our owne Land, although but in a few places, which is remembred by no author but *Bauhinus* in his *Prodomus* and *Pinax*.

1. *Numularia vulgaris.* Common Money-wort.

The common Money-wort, ſendeth forth from a ſmall threddie roote, divers long, weake, and ſlender branches, lying and running upon the ground, two or three foote long or more, ſet on both ſides with leaves, with two at a joynt, one againſt another, at equall diſtances, which are almoſt round, but pointed at the ends, ſmooth and of a good greene colour: at the joynts with the leaves, from the middle forward, come forth at every joynt, ſometimes one yellow flower and ſometimes two, ſtanding each on a ſmall footeſtalke, and made of five narrow leaves, pointed at the ends, with ſome yellow threds in the middle, which being paſt, there ſtand in their places, ſmall round heads of ſeede.

Minor. There is one of this ſort, much leſſer than the former, not elſe differing.

2. *Numularia minor flore purpuraſcente.* Small Money-wort with purpliſh flowers.

This ſmall Money-wort ſpreadeth and runneth on the ground, in the ſame manner that the former doth, with two very little leaves, ſet at every joynt of the ſtalke, which are as round or more than the former, with a little point at the ends: the flowers likewiſe ſtand in the ſame manner at the joynts, but much ſmaller than they, and of a purpliſh red colour: after which come ſeede in round heads alike, but leſſer, as the roote is ſo likewiſe.

The Place.

Both the former ſorts grow in our owne Land, in moyſt grounds by hedgē ſides, although thē firſt morē plentifull

1. *Nummularia vulgaris.*
Common Money-wort.

Nummularia minor.
Small Money-wort.

2. *Nummularia minor flore purpurascente.*
Small Money-wort with purplish flowers.

plentifully, and almost every where, the last hath beene found with us also in sundry places.

The Time.

They doe all of them flower in *Iune* and *Iuly*, and their seede is ripe quickly after.

The Names.

It is called of the later Latine writers (for none of the ancient either greeke or Latines, have made any mention of it, unlesse it be *Ereuthedanum* of *Theophrastus*, *lib.9.c.* 14. as *Pena* thinketh, which *Gaza* translateth *Rubia*, but that the vertues thereof doe not agree herewith; and *Numulum* of *Plinye*, *lib.* 18. *c.*28. which is falsly set downe *Mimmulus*,) *Numularia* of the round forme of the leafe, like unto money. *Brunfelsius* and others call it *Serpentaria*, because it hath beene found that Serpents have helped themselves therewith being wounded, and *Centummorbium*, and *Gesner Centimorbia*, or *Centummorbia*, of the singularity to helpe diseases and wounds. Some have called it *Lunaria minor*. *Tabermontanus* (and others before him) calleth it *Hirundinaria*, some say, *quod hirundinis instar passim terræ adhereat*. *Bauhinus* hath made mention of the last. The *Italians* call it *Nummolaria*, the *French* *Monnoyere*, the *Germanes* *Egelkraut*, and *Pfeuningkraut*; the *Dutch* *Pennickecruijt*; and we in *English* Herbe two pence, or two penny grasse, but more usualy Money-wort.

The Vertues.

Money wort is somewhat cold, but very astringent, binding and drying, whereby it is singular good for to stay all fluxes of blood in man or woman, whether they be laskes, bloody fluxes, the flowing of womens moneth-ly courses, or bleedings inwardly or outwardly, also the weakenesse of the stomacke, that is given to casting, it is very good also, for all ulcers, or excoriation of the lungs or other inward parts; yet some shepherds and others doe thinke it is very hurtfull for their cattell to feede thereon, and that it causeth their lungs to blister, which assuredly is but a conceit or opinion, for no cold and binding thing was ever knowne to exulcerate. It is exceeding good for all wounds either fresh or greene, to heale them speedily, for old ulcers also, which by their

humidity, and by the fluxe of moiſt and ſharpe humours, are either ſpreading or long in curing, for all which purpoſes, the juice of the herbe, or the powder drunke in water, wherein hot ſteele hath beene often quenched, or the decoction of the dry or greene herbe in wine or water drunke, or the ſeede, juice, or decoction uſed to the outward places, to waſh or bathe them, or to have tents dipped therein, and put into them are effectuall.

CHAP. XL.

Paronychia. Whitlow wort, or Whitlow graſſe.

ALthough *Bauhinus* diſclaimeth all the ſorts of *Paronychia* expreſſed by all other Authours, referring them all to ſome one or other herbe, and although thoſe that I ſhall ſet forth here by that name, doe not fully anſwer the deſcription of *Dioſcorides*, yet becauſe divers worthy Authours have ſo called them, and I had rather if they have erred, erre with them, then be ſingular in error with *Bauhinus*, let them therefore receive their place here at this time.

1. *Paronychia major.* The greater Whitlow wort.

The greater Whitlow wort hath very many leaves lying on the ground, in a round compaſſe one by another, of three inches long, and one broad a peece, rough, hairy, of a darke greene colour, and ſomewhat dented about the edges, ſtanding upon ſhort footeſtalkes, from the middle of whom riſe up one or two ſmall round naked ſtalkes, with few or no leaves thereon, ſcarſe able to ſtand upright, but bending downewards, at the tops whereof ſtand ſmall white flowers, after which come ſmall long pods containing ſmall reddiſh ſeede, nothing ſo hot and ſharpe as the next.

2. *Paronychia altera minor.* The leſſer Whitlow-wort.

This other that is ſmaller, hath likewiſe divers leaves lying on the ground, leſſer then the former, ſomewhat like unto the leſſer Mouſeare, called Cats foote, but not ſo hoary, yet a little hairy, and of a yellowiſh greene

3. *Paronychia Alſines folio.* Common Whitlow graſſe.

4. *Paronychia altera rutaceo ſolum.*

4. *Paronychia inciſis foliis.* Iagged Whitlow graſſe.

colour from which ſpring divers ſmall ſtraight and creſted ſtalkes, halfe a foote high or more, branching forth at the toppes, where ſtand divers white flowers, unto whom doe follow very ſlender long pods, like thoſe of Flixeweed, full of ſmall reddiſh ſeede, as ſharpe and hot in taſte as Creſſes, the roote is ſmall, hard and wooddy.

3. *Paronychia vulgaris Alſines folio.*
Common Whitlow graſſe.

This is a very ſmall herbe, ſeldome riſing to be an handbreadth high, having many ſmall and ſomewhat long leaves, lying next unto the roote, ſomewhat like thoſe of Chickeweede, but ſomewhat longer and whiter, from whence riſe divers ſlender naked ſtalkes, bearing many white flowers one above another, exceeding ſmall, after which come ſmall flat pouches, leſſe then of any *Thlaſpi*, wherein is contained very ſmall ſeede, of a ſharpe taſte, the rootes are a few ſmall fibres.

4. *Paronychia foliis inciſis*, Iagged Whitlow graſſe.

This other Whitlow graſſe, hath ſome pale or reddiſh; greene leaves, cut in on the edges into two or three ſmall cuts, making them ſeeme like unto the leaves of Rue, or herbe grace; it hath fewer ſtalkes then the former, and ſuch like leaves but ſmaller, ſet thereon in ſome places, with ſome white flowers at the tops of the ſtalkes, which

which turne about like a Scorpions taile, greater then the other, and huskes that hold the ſeede greater alſo, the rootes are ſmall and fibrous.

The Place.

The two firſt ſorts are found upon open hils, and in the dryer grounds of them, both the laſt ſorts are often found together, that is either upon old ſtone or bricke wals, or in dry gravelly grounds, yet ſtill where it hath graſſe or moſſe or the like, growing neere to ſhadow it.

The Time.

They flower very earely in the Spring, for they are all paſt by the end of *Aprill*, and are not to be found all the Sommer following.

The Names.

Theſe are not as I ſaid, the true παρονυχία *Paronychia* of *Dioſcorides*, but received under that name by good Herbariſts, *Bauhinus* as I ſaid before diſclaimeth all the ſorts of *Paronychia*, & referreth them all to one plant or other, as he thinketh beſt, and therein I think he hath as much erred, as he thought others did, for althogh the *Paronychia prima Matthioli*, be true *Ruta muraria*, or *Salvia vitæ*, being of the taſte and quality of the reſt of the capillary herbes, as you ſhall heare when wee come to ſpeake of them in their proper place, and *Matthiolus* his *Paronychia altera*, be *Anthyllis Alſines folio*, yet how *Bauhinus* ſhould make the *Paronychia foliis inciſis ſive rutaceo folio* to be a *Sedum*, rather then the other, calling it *Sedum tridactylites tectorum*, I cannot well ſee; for the leaves thereof doe not lye compaſſing one another, as all or moſt of the *Seda's* doe, neither are the leaves thereof thicke, as moſt of them are, nor are the *Seda's* hot in taſte as theſe are, and although *Lonicerus* ſetteth forth the *Medica lunata*, (whoſe figure and deſcription I have given you in my former Booke) for a *Paronychia*, whereunto as he ſaith, *Dioſcorides* his deſcription doth not much vary, which is called alſo *Lunaria Italica*, as a difference from the *Lunaria Germanica*, which may be refuſed, yet in my opinion he hath erred as much as in the others, to make all the other here ſet downe to be *ſpecies* of *Burſa paſtoris*, and I cannot but mervaile alſo at *Gerard*, in that hee had meant, if he had lived to have ſeene his worke publiſhed againe, with the additions, to have made another *Paronychia*, by the name of *Paronychia Cambrenſis*, of an herbe that he had received from a friend that ſent it him, being gathered upon a mountaine in *Wales*, which is the *Pyrola Europæa alſines flore minor*, as by his deſcription may plainely appeare, but I muſt excuſe him in that, I thinke he never read, or marked what he read of *Pyrola Alſines flore*, ſpoken of before in the Chapter of *Pyrola*, and therefore he referred the plant upon ſight, unto the neereſt his wits would ſerve him. The firſt is called by *Thalius Piloſella ſiliquata major*, *Aizoon Telephium Dalechampij* by *Lugdunenſis*, and *Bauhinus*, *Burſæ paſtoris ſimilis ſiliquoſa major ſeu majoribus foliis*. The ſecond is *Thalius* his *Piloſella ſiliquata minor*, which *Geſner* calleth *Paronychia altera Myagri foliis*, and *Bauhinus Burſæ paſtoris ſimilis ſiliquoſa minor ſeu minoribus foliis*. The third is called *Paronychia Alſines folio*, by *Lobel*, *Lugdunenſis*, and *Camerarius*, *Paronychia vulgaris* by *Dodonæus*, *Thlaſpios minima ſpecies*, by *Thalius* who yet ſaith it may well be referred to theſe ſorts, by *Lugdunenſis Myoſoris altera ſpecies*, and by *Bauhinus Burſa paſtoris minor loculo oblongo*. The laſt which is *Paronychia inciſis foliis* and *rutaceo folio* by *Lobel*, *Paronychia altera* by *Dodonæus*, *Alſine petræa rubra* & *Paronychia tertia* by *Tabermontanus*. *Tragus* not knowing by what name beſt to call it, entituled it in his owne language *Hendelkraut*, and *Thalius* thereafter *Dactyliobotanon alterum*, and as I ſhewed you before, *Bauhinus* maketh it an *Aizon* or *Sedum*.

The Vertues.

There is no exact and certaine tryall made of late dayes of this herbe Whitlow-graſſe, whether it performeth the cure, *Dioſcorides* and *Galen* attribute unto their *Paronychia*, for being by taſte found to be ſomewhat hot and ſharpe, it hath not that drying faculty without ſharpeneſſe, that they ſay is in theirs, and therefore it is not probable to worke thoſe effects, to heale the impoſtumes that grow at the rootes of the nailes of a mans hand, and other hot inflammations and impoſtumes, but onely a generall ſuppoſition it hath from the name, that it will helpe whitlowes and fellons, that riſe upon the fingers, moſt uſually about the joynts of them, which is performed by a digeſting quality.

CHAP. XLI.

Anagallis. Pimpernell.

THere were formerly onely two ſorts of Pimpernell knowne to *Dioſcorides*, and the other ancient Authours, which are that with the red flower, and that with the blew, but our times have found out other ſorts, as ſhall be ſhewed in this Chapter, yet I doe not meane to ſpeake of any of the Brooke limes, or Water ſorts here, for they ſhall be entreated of in their proper place, which is among thoſe plants that delight to grow in watery places.

1. *Anagallis flore phæniceo.* Red flowred Pimpernell.

The Common Pimpernell hath divers weake ſquare ſtalkes lying on the ground, beſet all along with two ſmall and almoſt round leaves at every joynt, one againſt another, very like unto Chickweede, but have no foote-ſtalkes, for they doe as it were compaſſe the ſtalke, wherein it differeth from Chickeweede, the flowers ſtand ſingly, each by themſelves, at the joynts betweene them and the ſtalkes, conſiſting of five ſmall round pointed leaves, of a fine pale red colour, tending to an Oreng, with ſo many threds in the middle, in whoſe places after they are paſt, ſucceed ſmooth round heads like thoſe of Chickeweedes, wherein is contained ſmall ſeede, the roote is ſmall and fibrous periſhing every yeare.

2. *Anagallis flore cæruleo.* Blew flowred Pimpernell.

This other Pimpernell, is in all things like unto the former, ſaving onely in the colour of the flower, for whereas that is of a red colour, this is of a faire blew colour, wherein conſiſteth the difference.

3. *Anagallis flore obſolete purpurea.* Pimpernell with ſullen red flowers.

This Pimpernell doth in all things likewiſe reſemble the former, ſave that the flowers hereof are of a ſullen or darke red colour, having a glimpſe of purple therein,

4. *Anagallis flore carneo.* Pimpernell with bluſh coloured flowers.

Of the ſame kinde alſo is this other, not differing in any thing, but in the colour of the flower, which is of a faire bluſh or incarnate colour.

5. *Anagallis flore luteo.*

Pimpernell with yellow flowers.

The yellow Pimpernell groweth in the like manner, that the former doe, with many ſpreading branches upon the ground, but they are ſomewhar greater, and ſo are the leaves alſo, larger then the former ſorts, but ſet by couples at the joynts, where the flowers come forth upon long footeſtalkes, like unto the other, but larger or greater, and of a faire yellow colour, with pointed leaves ſomewhat like unto *Numularia*, withround heads alſo containing the ſeede, and ſmall fibrous rootes not periſhing every yeare, as the reſt doe; for with the plant in flower, which I have gathered, there hath remained the dry ſtalke, with the heads of ſeede, of the former yeares growing.

6. *Anagallis tenuifolia flore cæruleo.*

Narrow leafed Pimpernell with blew flowers.

This blew flowred Pimpernell, groweth in the ſame manner that the reſt doe, with ſpreading branches upon the ground, and leaves ſet at the ſeverall joynts thereof, all along up to the toppes, but they are longer and narrower, ſomewhat reſembling the leaves of *Gratiola*, or hedge Hyſſope, and not alwaies two at a joynt, but oftentimes three, or peradventure more, yet very ſeldome: at the joynts likewiſe with the leaves, ſtand ſeverall flowers as in the other ſorts, upon ſmall long footeſtalkes, made of five ſmall round pointed leaves, yet ſomewhat greater then thoſe of the former blew ſort, having a ſhew or circle of a purple colour in the middle, or bottome: which afterwards yeeld ſuch like round heads and ſeedes, and having ſmall threddy rootes like unto the other, periſhing in the ſame manner every yeare.

The Place.

The firſt groweth every where almoſt, as well in thē medowes and corne fields, as by the wayes, or in gardens

1.2.3.4. *Anagallis floribus phœniceis, cæruleis, obſolete purpureis & carneis.* Pimpernell of foure ſorts of colours in the flowers. that is, red, blew, ſullen red, and bluſh colour.

5. *Anagallis flore luteo.*
Pimpernell with yellow flowers.

6. *Anagallis tenuifolia flore cæruleo.*
Blew flowred Pimpernell.

arising

ariſing of it ſelfe: the ſecond is nothing ſo common, yet is found growing neere *Battle* by *Oxford*, and plentifully in *Rumney* Marſh, at *Higham Ferrers*, *Artilborrow*, and *Raundes* in *Northamptonſhire*, and at *Beconsfield* in *Buckinghamſhire*. The third as *Cluſius* ſaith, firſt grew with him, in his Garden at *Franckford*, and continually by the ſhedding of the ſeede, preſerved it owne kinde, as well there, as in *Holland* at *Leyden*. The fourth grew of it ſelfe, in my owne Garden here in *London*, and commeth up every yeere, of it owne ſowing. The fift groweth in the ſhady places of *Hampſted* wood, and in many places of *Kent*, and about *Aſhford*, at a place called the Parke. The laſt *Cluſius* ſaith he had from the noble and learned *Iohn Monnel* of *Tornay*, who received it from *Cadis*, or *Calis*, where it grew; and grew likewiſe in his garden at *Tornay*.

The Time.

They doe all flower from *May*, unto *Auguſt*, and the ſeede ripeneth in the meane time, and falleth.

The Names.

It is called in Greeke Ἀναγαλλὶς, *Anagallis*, and ſo likewiſe in Latine. *Pena* thinketh it might take the name Γαλλὶς, *quod Græce dicebatur Hyacinthus unde a colore Hyacintheo, Anagallis nuncupari potuit: vel fortè dixit antiquitas Anagallidem, quia ſuperbula floribus venuſtis vias paſſim ornet, colore oculis grato & amico.* *Iacobus Manlius*, and *Matthiolus* after him, call it *Morſus Gallinæ*, and *Morgelina*, but that name is more truely the name of *Alſine* Chickeweede, whereof this may be accounted a *ſpecies*. Some have called it *Auricula Muris*, following therein the *Pandectarum author*. *Dioſcorides* ſaith, that in his time it had divers names, among which he numbreth *Macia*, which *Marcellus Virgilius* alſo remembreth, and *Corchorus*, and *Halicacabus*, whereby it is ſuppoſed to be the *Corchorus* of *Theophraſtus*, which in his ſeventh booke, and ſeventh chapter, he reckoneth *Inter olera*, among the pot herbes, or ſallet herbes; and for the bitterneſſe became a Proverbe κόρχορος ἐν λαχάνοις, *Corchorus inter olora*; which is underſtood of thoſe men, that would be eſteemed of ſome worth and account among others, when they are the vileſt of others, for ſo *Plinye*, in his twenty fift booke, and thirteenth chapter, doth ſay that this *Anagallis Pimpernell*, was called *Corchorus*, or *Corcorus* in the ſame manner: but not that *Corchorus* he mentioneth, in his 15. booke, and 32. chap. which as I ſayd before, is more truely taken to be *Melochia*, *Olus Iudaicum*, the *Iewes* Mallow. *Paulus Ægineta* uſed the male Pimpernell in the compoſition. *Diacorallion*, becauſe it was called *Corallion*, whereof he ſpeaketh in his ſeventh booke, which is uſed againſt the diſeaſes of the Arteries and joynts, and was to be made with this herbe, which ſome doe rather thinke ſhould be called, *diacollarion*, and the herbe *Collarion*, which may ſeeme to take the name of glewing, which is proper to Pimpernell. Some alſo take this to be the *Melochia* of *Serapio*, but *Serapio* calleth the *Anagallis flore phæniceo*, which is generally called *Mas*, In the *Arabian* tongue *Xantala*, and the other *flore cærulea*, which is the *Femina Cardabella*, as *Tragus* ſaith. The *Italians* call it *Anagallo*, and *Morſo di gallina*. The *Spaniards Murages*. The *French Mauron* and *Morgeline*. The *Germanes Gauch heiil, quaſi ſalus fatuorum*, or *coccygis ſive cuculi*, for ſo they call *Gauchbrot Panis cuculi*, and *Gauch blum flos cuculi*, from a ſuperſtitious conceit as it is thought, that it being hung over the threſhould of the porch or dore, will fruſtrate or expell all witchcraft or ſorceries. The *Dutch*, *Guichel heil*: and we in *Engliſh* Pimpernell. The firſt here ſet downe is generally of all writers called, *Anagallis mas & flore phæniceo*, as the other, or ſecond, *Anagallis fœmina flore cæruleo*. The third *Cluſius* maketh mention of in his hiſtory of plants. The fourth is not remembred or ſpoken of by any other but my ſelfe: the fift is generally called *Anagallis lutea*, but of *Geſner in hortis Germaniæ Numularia ſylvatica & mas*, and of *Lugdunenſis Alſine lutea*. The laſt *Cluſius* calleth *Anagallis tenuifolia Monelli*, and *Bauhinus Anagallis cærulea foliis binis terniſve, exadverſo naſcentibus*.

The Vertues.

Pimpernell as *Galen* ſaith, in his ſixth booke, of the faculties of ſimples, of both ſorts with red or blue flowers, are of a clenſing faculty, they have alſo an attractive heate, whereby they draw forth thornes or ſplinters, or other ſuch like things faſtned in the fleſh, and therefore the juyce put up into the noſtrils, purgeth the head; briefely alſo they have a drying faculty without ſharpeneſſe, whereby they are good to ſoder the lippes of wounds, and to clenſe foule ulcers; thus ſaith *Galen*; whereby it is plaine, that they erre greatly, that make Pimpernell, to be cold and moyſt, when as they are quite contrary hot and dry, and of ſuch a clenſing quality, that the diſtilled water or juyce, are by the *French* Dames accounted mervailous good to clenſe the skinne from any roughneſſe, deformity or diſcolouring thereof, and to make it ſmooth neate and cleere: being boyled in wine and given to drink, it is a good remedy againſt the Plague, and other Peſtelentiall Fevers, and contagious diſeaſes, ſo as after the taking thereof warme, they lye in their beds, and ſweate for two houres after, and hereby the venome of the diſeaſe would bee expelled, yet ſo as that it bee uſed twice at the leaſt: the ſame alſo helpeth all ſtingings and bitings of any venemous beaſts, be they of Serpents, as the Viper, Adder, or Scorpion, or madde dogges, or any other, uſed inwardly, and applyed outwardly: the ſame alſo openeth the obſtructions of the Liver, and is very availeable againſt the infirmities of the raines, provoketh urine, and helpeth to expell the ſtone and gravell out of the Kidnies and Bladder, and conduceth much in all inward wounds, and ulcers. The decoction or the diſtilled water, is no leſſe effectuall, to be outwardly applyed to all wounds, be they freſh, to conſolidate them, or old filthy or fretting and running ulcers, venemous alſo, or infected, by clenſing their corruption, by reſtraining their malignant corroding, and infectious qualities, by drying up their fluxe of humours, which hindreth their cure, and quickly bringing them to healing: a little honey mixed with the juyce, and dropped into the eyes, clenſeth them from cloudy miſtes, or filmes growing over them, which hinder and take away the ſight: it helpeth the toothach being dropped into the eare, on the contrary ſide of the paine: it is effectuall alſo to eaſe the paines of the hemorrhoides, or piles: the male Pimpernell is ſayd to drive forth the fundament, and the female to repell it, and drive it into his place againe, whereby it is found that the male is more powerfull in expelling, and the female in repelling.

CHAP.

Chap. XLII.

Androſaces altera Matthioli. *Matthiolus* his Navelwort.

ALthough theſe plants conteined in this Chapter, be referred to the Chickwëedes, by divers authors, and might therefore have beene placed among them, yet in regard I finde them not onely to vary from all the ſorts of Chickweedes, as well in the outward forme, as in the inward qualities, as by the taſte may plainely be diſcerned, I have therefore thought good to ſeparate them, and ſpeake of theſe in this Claſſis, and of them in another.

1. *Androſaces major Matthioli.* *Matthiolus* his *Androſace* called the greater Navel-wort.

The greater hath diverſe ſomewhat broade freſh greene leaves, a little hayrie, lying upon the ground, ſomewhat reſembling a Plantaine leafe, with ſome ribbes in them, but much ſmaller, and a little unevenly dented about the edges: from among which riſe up divers round ſtalkes, foure or five inches high, ſomewhat hayrie alſo, bare or naked without a leafe up to the toppes, where ſtand foure or five leaves, like thoſe that grow below but leſſer, and among them ſtart forth divers ſlender foote-ſtalkes, bearing every one of them a ſmall white flower, conſiſting of five ſmall notched leaves, ſtanding in a greene huske, divided alſo at the toppes into five parts, wherein after the flower is paſt, ſtandeth a ſmall round head, containing ſmall blackiſh ſeede: the roote is ſmall and fibrous, periſhing as ſoone as it hath borne ſeede; and riſeth often of it owne ſowing againe, which if it ſpring before winter, or that it doth not runne up for flower, the firſt yeere of the ſowing, will abide the firſt winter, and flower the ſommer following.

1. *Androſace altera major Matthioli.*
Matthiolus his *Androſace* called Navel-wort.

2. *Androſaces minor.* The leſſer *Androſace*, or *Matthiolus* Navel-wort.

The leſſer Navel-wort groweth like the former, with many leaves lying on the ground, but they are ſmaller and narrower by much, yet ſomewhat hayrie, and dented about the edges; from whence riſe alſo many ſmall naked hayrie ſtalkes, three or foure inches high, not having any leaves at the toppes like the former, but an umbel or tuft, of many ſmall flowers, like the former but whiter; after which come forth ſuch like ſmall round heads with ſeede: the roote is likewiſe ſmall and fibrous, but more reddiſh, and periſheth every yeere, after ſeede time.

3. *Androſaces minima.* The leaſt *Androſace* or *Matthiolus* Navel-wort.

The leaſt Navel-wort is alſo very like the former, with many hayrie leaves, lying in a round compaſſe upon the ground, very like unto the leaves of the ſmalleſt Sheapheards purſe, with more pointed and deeper dented edges, than either of the former: the ſtalkes that riſe from among them are much ſmaller than the former, ſo are they ſhorter alſo, but not leſſe hayrie, having five ſmall greene leaves, ſet in a round compaſſe at the joynt, which is about the middle height, from whence ariſe as in the firſt ſort, three or foure ſmall white flowers, which afterwards beare ſeede in ſmall heads like the former: the roote is alſo a few threds as the reſt, and anſwerable to the plant.

The Place.

Theſe all grow in divers places of *Germany*: the firſt in *Auſtria* in the cornefields about *Baden*, and *Vienna* as *Cluſius* writeth, although *Matthiolus* his friend that ſent it him, ſayd it was brought out of *Syria*: the ſecond Doctor *Burſerus* gathered neere a village called *Markerſon*, about foure miles from *Herbipolis*, as *Bauhinus* in his *Prodomus* ſetteth it downe. The laſt he ſaith likewiſe Doctor *Furerus* told him, groweth in the plaines of *Northuſa*.

The Time.

They doe flower in *May*, and their ſeede is ripe in *Iune* and *Iuly*, yet the laſt is the earlieſt of the reſt, both for flower and ſeede.

The Names.

Ἀνδρόσακες in Greeke, is called alſo in Latine *Androſaces*, *ut quis forte putare poſſit* ὑδρόσακες *ab urina & hydropicorum aquis educendis*, yet this is not the right *Androſaces* of *Dioſcorides* and *Galen*, becauſe he ſaith it groweth without leaves, as it is extant in ſome copies, yet in others it is ſaid to have leaves, having onely a head with ſeede, *Matthiolus* firſt exhibited two plants under the name of *Androſaces*, the one which is a Sea plant, ſent unto him, as he ſaith from *Lucas Ghinus* of *Piſa*, who found it about the Sea coaſts in *Hetruria*, *Tuskany*, or *Florence*, which doth not anſwer unto the Text of *Dioſcorides*, who ſaith *folliculum in capite habet in quo ſemen*, it hath a huske at the toppe, wherein is the ſeede, and therefore *Bellenius* called the *Polygonum quartum Plinij*, which

which is the leſſer *Uva marina*, or Sea Grape, by the name of *Androſace*, as it is declared before in the Chapter of *Polygona baccifera*, Berry bearing Knotgraſſes, *Anguillara* accounteth the *Cuſcuta* to be the *Androſace* of *Dioſcorides*, which is without leaves, according to thoſe copies that have it ſo, and as *Tragus* before him doth, who ſaith that *Antonius Muſa*, and *Ericius Cordus* were of the ſame minde before him, which is not without ſome probability, in that it carryeth no leaves but heads of flowers and ſeede, upon a number of ſmall threds, but that this is not of a Sea plant, as *Dioſcorides* his *Androſaces* is, nor is white as ſome copies have it, or with ſlender ruſhy ſtalkes, as other copies have, and therefore I thinke we may eaſily conclude, that *Cuſcuta* is not *Dioſcorides* his *Androſaces*, but the *Uva marina* Sea Grape, may be thought & is by many, to come neerer therunto, and I ſhould with *Bellonius* thinke ſo alſo of it, if it were an herbe, and not a ſhrubbe, and if it had white and ſlender ſtalkes, as it hath wooddy, and climing, bearing red berries, which it is likely *Dioſcorides* would not have omitted, if he had meant that plant, and for that firſt Sea plant of *Matthiolus*, for any thing we can perceive it is but an excreſcence of the Sea, not bearing any heads with ſeede, but ſmall round Navell-like leaves, and therefore at *Mompelier*, called *Vmbilicus marinus*, which grow hard and white, being out of the water, although tender underneath it, as *Corall*, *Coralline*, and ſome other Sea plants doe, whereof you ſhall heare more in the proper place, which is of Sea plants, the other *Androſace* that *Matthiolus* ſetteth forth and calleth *altera* was ſent him as he ſaith, by *Cortuſus*, for *Androſace*, which although it agree not unto that of *Dioſcorides*, yet all other writers ſince, have ſo called it, but both *Cluſius* and *Lobel* deny it to be any Sea plant however *Cortuſus* ſaith, it came from the places, neare the Sea in *Syria*. The firſt here deſcribed is generally called *Androſaces altera Matthioli*, who as it ſhould ſeeme, held the reading of *Dioſcorides* his text, to be *tenues ſpargens juncos cum folijs*, ſpreading ſmall ruſh like ſtalkes with leaves, for ſo hath this plant, and as I ſaid before is referred to the kindes of *Alſine*, Chickweede; but for the reaſons before aledged, I doe as ye ſee diſtinguiſh them, but *Bauhinus* calleth it *Alſine affinis Androſaces dicta major*. The ſecond is called by *Bauhinus* in his *Pinax* and *Prodromus*, *Alſine affinis Androſace dicta minor*. And the laſt is called alſo by him, in the places before named, *Alſine verna Androſaces capitulis*. I have called it in *Engliſh*, (not ſimply Navel-wort, for I ſee no reaſon why ſuch a name ſhould be given it) as others doe, but *Matthiolus* his *Androſace*, or Navel-wort, as a diſtinction betweene it and the *Cotyledon altera*, called alſo Navel-wort.

The Vertues.

This Navel-wort, being ſomewhat ſharpe in taſte, is accounted hot and dry in the ſecond degree, and doth both clenſe old ſores and ulcers, and ſtayeth thoſe that are corroding or fretting from their malignity, and afterwards dryeth up the ſuperfluous humidity, which hindereth their healing, and clenſeth alſo the skinne outwardly from roughneſſe, Sunburning or the like diſcolouring, the juice clarified and dropt into the eyes, clenſeth them from thoſe filmes or skinnes, that by growing over the ſight, cauſe blindeneſſe.

CHAP. XLIII.

Sagina Spergula. Francking Spurry or Spurrewort.

THeſe plants alſo as the former, I might as others doe, referre unto the kindes of Chickeweedes, but their qualities being not alike, nor the forme of them, but very little conformable, I muſt likewiſe for this worke diſjoyne them, howſoever for another they may be joyned.

1. *Sagina Spergula major.* The greater Franck Spurry, or Francking Spurrewort.

The greater Spurry or Spurrewort, ſendeth forth divers ſmall round and upright ſtalkes, ſcarſe halfe a foote high, whereon at ſeverall diſtances or joynts, grow many ſmall and narrow leaves, ſet together in the manner of a ſtarre, or the rowell of a ſpurre, whereupon came the name, the flowers are many, ſmall, and white, ſtanding at the toppes of the ſtalkes, which turne into ſmall round heads, containing therein blacke ſeede, the roote is ſmall and threddy, periſhing every yeare after ſeede time.

2. *Sagina Spergula minor.* The leſſer or Sea Spurry.

This Sea Spurry is not much differing from the former, but that it hath not ſo many long and narrow leaves ſet together at the joynts of the ſtalkes, which doe not riſe fully ſo high, and doe ſomewhat more leane downewards to the ground, which together with the leaves are more white, and of a ſaltiſh or brackiſh taſte, if it grow neere the Sea ſide, as moſt Sea plants are, otherwiſe nothing ſo hoary white, or brackiſh at all, the flowers likewiſe are fewer, but of a white colour, and the ſeede blacke like the other, the roote is likewiſe, ſmall, long and ſomewhat hard, with ſmall fibres thereat.

3. *Sagina Spergula minima.* The leaſt Franck Spurry.

The ſmalleſt Spurry hath likewiſe divers weake ſtalkes, but ſomewhat bowing downe to the ground, ſeldome above an handbredth high, full of joynts, and at every of them, two ſmall ſhort leaves, compaſſing them at the bottome, from betweene the ſtalkes and the leaves come forth other ſmall leaves without number, towards the toppes of the ſtalkes from the ſaid joynts come forth the flowers, every one upon a ſmall footeſtalke, which are of a pale blew colour, and ſometimes more blew, or tending to a purple, after which come ſuch like round heads with blacke ſeedes in them, as are in the former, the roote is ſmall and long, with ſome fibres, or threds at it.

4. *Aſterias ſive Stellaria Monſpelienſium.* *French* Spurry, or Spurrewort.

The *French* Spurry, is likewiſe not much differing from the laſt ſort, but that the ſmall ſhort and narrow leaves, that ſtand at the joynts of the ſmall low ſtalkes, are all of an equall length, and being ſtiffer and harder, ſtand ſtraight outright in an equall diſtance, one from another like a ſtarre, the flowers hereof are ſmall, having five narrow pointed leaves laid open abroad like a ſtarre alſo, but of a reddiſh colour, ſo that whether you reſpect the leaves or the flower, they both reſemble a ſtarre, and from thence tooke the name, and yet we know there are many other herbes ſo called, much differing one from another.

The Place.

Theſe doe all grow in dry ſandy grounds, as well among the Corne in divers Countries, as in untilled and

shadowy places, especially the first and second, although it is also found growing neare the Sea shore in the like places.

The Time.

They flower in *Iune* and *Iuly*, and the seede is ripe usually in *August* before Harvest time.

The Names.

It is called *Spergula* of all those that have written thereof, except *Thalius*, who calleth it *Anthylloides*, and *Fabius Columna*, who calleth the first, *Alsine tenuifolia altera, vel sylvestris altera, tricophyllos*. *Lobel* calleth it *Sagina Spergula, a saginandis pecoribus*, from the Francking or feeding fat of cattle, and therefore he saith, that divers *Brabanders* and others in the Low Countries, did sow their grounds therewith, for the same purpose, to cause their Kine to give the more store of milke. *Bauhinus* calleth them *Alsine Spergula*. The last *Lugdunensis* maketh mention of, under the same name in the title. Both the *Dutch* and we in *England* call it Spurry, or Franck Spurry, for the causes aforesaid, but I do a little more explaine the names, in calling it Francking Spurrewort.

The Vertues.

The seede is held to be a provoker to vomit, and thereby to bring forth flegmaticke and foule slimy humours, that sticke in the stomacke, both troubling the body, and hindering digestion, and health, the herbe a little bruised and laid to the fingers, or other places that are cut, will speedily heale them, whereof the Country people in divers places, say they have had good experience. It fatteneth cattle as you have heard before, and so it doth also Pullaine, and as it causeth the Kine to give more store of milke then ordinary otherwise, so it causeth Pullaine likewise to lay more store of egges, which is no idle conceit, for those of *Brabant*, and other the parts thereabouts have found it sufficient true, by their daily use and tryall thereof.

1. *Sagina Spergula major.*
The greater Franck Spurry.

CHAP. XLIIII.

Asperula. Woodroofe.

THere are two or three sorts of this herbe Woodroofe, whereof although some be common, and well knowne, yet the others are not so.

1. *Asperula odorata.* Common Woodroofe.

The Common Woodroofe, or Woodrowell, sendeth forth divers square stalkes, halfe a foote high or more, full of joynts, and at every joynt seaven or eight faire greene shining leaves, broader then those of Clevers, in a manner smooth or but little rough at all, at the toppes of the stalkes stand foure or five white sweete smelling flowers, made of five leaves a peece, laid open like a starre, after which come small round seede, a little rough, or cleaving to whatsoever it toucheth, the roote runneth creeping under ground, and shooteth up new stalkes round about it every yeare.

2. *Asperula flore cæruleo.* Woodroofe with a blew flower.

This Woodroofe hath seldome more then one round stalke, rising from the roote, set full of joynts, at every one whereof stand divers small and somewhat long greene leaves compassing it, not so smooth and greene as the former, and likewise small branches, from the bottome almost up to the toppe, set with the like leaves but smaller, where the flowers stand three or foure together, each upon a small footestalke, which are of the same greatnesse with the former, or rather somewhat lesse, and of a faire blewish purple colour, without any sent at all: and after they are past, in their places grow small round browniſh seede, not rough at all, the roote is small, somewhat yellowish and fibrous, and perisheth every yeare, and from the seede when it falleth, springeth new plants every yeare.

3. *Asperula purpurea.* Woodroofe with a purple flower.

This is very like unto the last, but with more store of stalkes, and fewer pale greene leaves at the joynts of them, having purplish flowers, and small fat oylie seede.

4. *Asperula Muralis minima.* Small stony Woodroofe.

This small Woodroofe, (which doth in my judgement, better resemble *Gallium* then *Asperula*, yet because others so call it, I am content to let it so passe also) hath divers square, rough, and upright stalkes, about halfe a foote high, which are in a manner transparent, being full of joynts, and at every joynt sometimes foure or five but usually stand sixe small rough greene leaves, somewhat hairy and bitter in taste: at the joynts above the leaves come forth the flowers, round about the stalkes, at certaine distances up to the toppes of them, which consist of foure small yellowish leaves, the roote is threddy and small, perishing also every yeare in these Countries.

1. *Asperula aut Aspergula odorata.*
Common Woodroofe.

2. *Asperula cærulea.*
Woodroofe with blue flowers.

The Place.

The first is found in the open woods of *Germany* and other places oftentimes, but is most usually planted in gardens, as the second is also. The third groweth as well in the fields as gardens, about *Lyons*. The last *Columna* saith, hee found in stony or rockie places, on the hils *Valvenses*, which are in the Kingdome of *Naples*.

The Time.

They doe all flower early, even about *May*, and their seede is ripe while they are yet in flower, or presently after.

The Names.

It is generally called *Asperula*, *Aspergula* or *Spergula*, *& odorata* is put to the first, to distinguish it from the other, and not mentioned by any of the antient writers, except it be as *Gesner in collectione stirpium*, thinketh it to be *Alyssum minus* of *Plinye*, in his 26. booke, and 9. chap. and some others that tooke it to be *Alyssum Galeni*, but erroniously: the first hath beene diversly taken, of divers of the later writers; for *Brunfelsius* calleth it *Caprifolium, vel Stellaria*, or *Herba Stellaris*, and *Hepatica quarta*. *Tragus*, *Cordus*, *Lonicerus*, and *Thalius* call it *Matrisylva*. *Dodonæus*, *Lobel*, and *Lugdunensis*, *Asperula*. *Clusius* and others *Asperula odorata*. *Pena* in *Adversariis*, *Aspergula odora nostras*; *Cordus* upon *Dioscorides Aparine sylvestris quædam*. *Gesner* in his *Appendix Rubia sylvestris alia minor*, and *Tabermontanus Hepatica stellata*: but generally now adayes it is called of most men *Asperula odorata*, although it hath but little roughnesse therein at all, save onely as I sayd in the seede: the *Italians* call it *Asperulla*: the *French Mugnet*: the *Germanes Hertzfroidt*, *waldneister*, *& Leberkraut*: the *Dutch Waltneester*: and we in *English* Woodroofe, and Woodrowell: the second is called *Asperula cærulea*, by *Dodonæus*, *Lobel*, *Camerarius*, and *Lugdunensis*, and our *English Turner* calleth it *Alysson*, and so doe others also but falsely. *Bauhinus* calleth it *Asperula cærulea arvensis*: the third is called *Myagrum alterum minus Dalechampii* by *Lugdunensis*; and *Asperula hexaphyllos purpurea* by *Bauhinus*. The last is called by *Columna Asperula verticillata muralis minima*, and by *Bauhinus Asperula verticillata luteola*.

The Vertues.

The *Germanes* doe account very highly of this Woodroofe, using it very familiarly in wine, like as we doe Burnet to take away melancholy passions, to make the heart merry; and to helpe the stomacke dejected, unto a good appetite, and the Liver being oppressed and obstructed: it is held also to be good against the Plague, both to defend the heart, and vitall spirits from infection, and to expell the noysome vapours that are received: it helpeth also to dissolve hard impostumes, being bruised and applyed, and in the same manner many Country people use it, for any fresh or greene wound, or cut in the flesh any where: the distilled water of the herbe is no lesse effectuall, for the purposes aforesayd, either inwardly or outwardly.

CHAP.

CHAP. XLV.

Gallium. Maidens haire, or Ladies Bedstraw.

OF *Gallium* Ladies Bedstraw, there are diverse sorts, some growing with us, others rare, and brought from other places, all which is fit that we should joyne in one chapter, as followeth.

1. *Gallium luteum vulgare.* The common Ladies Bedstraw.

This Ladies Bedstraw riseth up with divers small browne and square upright stalkes, a yard high or more, sometimes branched forth into divers parts, full of joynts, and with divers very fine small leaves, at every one of them, little or nothing rough at all: at the toppes of the branches grow many long tufts or branches of yellow flowers, very thicke set together, one above another; from the severall joynts, which consist of foure small leaves a peece, which smell somewhat strong or resinous, yet not unpleasant; the seede is small and blacke, like Poppie seede, two for the most part joyned together: the roote is reddish, and hath many small threds fastned unto it, which take strong hold of the ground, and creepeth a little also, and the branches leaning a little downe to the ground, take roote at the joynts thereof, whereby it is easily encreased.

2. *Gallium flore rubro.* Red flowred Ladies Bedstraw.

This small plant hath slenderer and lower stalkes than the former, yet divided into many branches, at whose joynts stand 4. 5. or 6. long leaves, and not of so darke a greene colour: the flowers are of a red colour, not so thicke set together as the former, consisting of foure small pointed leaves, with a yellow pointell in the middle, but 5. or 6. or more standing together at the toppes of the branches at the most, which afterwards turne into small blacke seede like the former; the roote also is reddish like it, but greater and creepeth not, abiding many yeeres, and perisheth not. Like hereunto is that *Gallium nigro-purpureum montanum tenuifolium* of *Columna*, which therefore I doe but onely remember here, not thinking it to be a differing *species* from it, although the flower bee in some places a little darker, they are so like in all things, although *Bauhinus* doth make them divers.

3. *Gallium flore albo major sive Mollugo montana.* Mountaine white flowred Ladyes Bedstraw.

The white flowred *Gallium*, which is the greater *Mollugo*, shooteth forth from the roote, which is blacke, and very threddy or fibrous, a number of slender and weake stalkes, which yet stand upright of themselves, diversly branching forth into many parts, so that it maketh shew of a pretty well spread bush, having many shorter and broader smooth greene leaves, set at the joynts, than any of the former, or the next that followeth: the flowers

1. *Gallium Luteum.*
Common Ladies Bedstraw.

2. *Gallium flore rubro.*
Red flowred Ladyes Bedstraw.

are

are very ſmall and white, ſtanding at the toppes of the branches, more thickly or plentifully ſet than the other, with red flowers before, which likewiſe turne into ſmall blacke round ſeede.

4. *Mollugo vulgatior.* The common white flowred Ladies Bedſtraw.

This is in all things like the laſt, but that the branches are ſo weake, that unleſſe they be ſuſtained by the hedges, or other things neere which it groweth, it will lye downe on the ground; and the leaves are ſmaller and narrower, yet not ſo ſmall as the former, with yellow flowers; the flowers are likewiſe ſmall and white, but not plentifully ſet thereon: and the roote threddy and abiding; ſome doe make a ſmaller ſort hereof, which is not a proper *ſpecies*, for upon tranſplanting it will grow as great as the laſt.

5. *Gallium montanũ Creticum.* Mountaine *Candy Gallium.*

Gallium montanum Creticum groweth like the ordinary but much leſſer, with greater rootes and branches: it is a more effectuall rennet than the other, it is hot and aſtringent, ſtaying fluxes of blood.

6. *Gallium montanum alterum.* Another ſmall *Candy Gallium.*

The rootes are ſmall and wooddy; it hath two or three ſmall, long leaves, broad pointed and whitiſh flowers, ſtanding in ſpikes.

The Place.

The firſt and the fourth are frequent in many places of this Land, in Meddowes and Paſtures both wet and dry, and by the hedges: the ſecond was found in *Italy*, as *Cluſius* ſaith, and *Columna* his in the Kingdome of *Naples*: the third is found in *Germany*, on divers hils there; the two laſt in *Candye*.

The Time.

All theſe are in flower in *May*, for the moſt part, yet that with the red flower is later than the other, & flowreth not untill *Iune*: the ſeede is ripe in *Iuly* and *Auguſt*.

4. *Gallium album ſive Mollugo vulgatior.*
The common white flowred Ladies Bedſtraw.

Minus flore albo

The Names.

It is called in Greeke γάλλιον, and in Latine alſo *Gallium*, or as others have it γάλιον *Galium*, and as *Dioſcorides* ſaith, of ſome γαλέριον, & γαλάριον *Galerion* and *Galarion*, and was ſo called from the effect, which is to cauſe the milke to gather into a curd, when they ſet it to make cheeſe; and therefore in many Countries, as well here as beyond the ſeas, they call it Cheeſe rennet, and ſerveth for that purpoſe very well The firſt is generally called of all writers, without variation *Gallium*, and *Gallium luteum*. The ſecond *Cluſius* firſt made mention of, and then *Columna* by the names formerly ſet downe. The third is the *Mollugo montana* of *Dodonæus*, *Cluſius*, *Lobel*, *Lugdunenſis*, *Thalius* and *Tabermontanus*. *Geſner in hortis* calleth it *Rubia ſylvatica altera, & major* in his *Appendix*, and is the ſecond *Matriſylva* of *Tragus*. The fourth is the *Mollugo vulgatior herbariorum* of *Lobel*, and the *Mollugo prima* of *Dodonæus*, *Lugdunenſis*, and *Tabermontanus*; it is *Tragus* his third *Gallium*, and called of *Camerarius*, *Thalius*, *Pena* and others *Gallium album*. The two laſt are mentioned by *Alpinus* in his book *de plantis exoticis*. The *Italians* call it *Galio*, the *Spaniards Coaja leche yerva*: the *French Pety Muguet*: the *Germaines Walſtro*, and *Unſerlichen frawen Betſtro*, and *Magerkraut*, of helping of the dry ſcabbe in children, which they call *Megerey*: the *Dutch Walſtroo*, and we in *Engliſh*, our Ladyes Bedſtraw, according to the *Germane* name, or Cheeſe rennet, and Maides haire in divers Countries of this Land.

The Vertues.

The decoction of the hearbe, I meane the common Ladies Bedſtraw, being drunke, is uſed by divers, to helpe to provoke Vrine, and thereby to fret and breake the ſtone: the ſame alſo drunke helpeth to ſtay inward bleedings, as alſo to heale inward wounds, by the drying and heating qualities therein, the herbe as the flowers being bruiſed, and put up into the noſthrils, ſtayeth their bleeding likewiſe. *Dioſcorides* writeth that the roote is good to provoke bodily luſt, and ſome ſay the flowers doe ſo alſo: the flowers and the hearbe likewiſe made into an oyntment or oyle, in oyle to be inſolated or ſet into the Sunne, and changed after it hath ſtood ſome tenne or twelve dayes, but if it be made into an oyntment, it muſt be boyled in *Axungia*. or ſallet oyle, with ſome waxe melted therein after it is ſtrayned; which will helpe burnings with fire, and ſcaldings with water: the ſame alſo or the decoction of the herbe and flowers, is good to bath the feete of traveilers, who are ſurbated with travaile, and for Lackies or ſuch like, whoſe running long, cauſeth not onely wearineſſe, but ſtiffeneſſe in their ſinewes and joynts; for which both the decoction warme is very availeable, and ſo is the oyntment to uſe afterwards: the ſame alſo as is ſayd before, helpeth the dry ſcabbe, and the itch in children, whereof the *Germanes* doe make dayly experience: theſe ſorts with white flowers have beene thought unprofitable, and of no uſe: but *Cluſius* ſaith, the poore women in *Auſtria*, *Hungaria*, and other places in *Germany*, that gather herbes and rootes for their uſes that neede them, bringing them to the market to ſell, calleth it *Gleidkraut*; and by their experience have found it good, for the ſinewes, arteries, and joynts, to bathe them therewith, both to take away their wearineſſe, and weakeneſſe in them, and to comfort and ſtrengthen them alſo, after travaile, cold, or paines.

CHAP. XLVI.

Cruciata. Crossewort.

WEe have formerly knowne but one sort of *Cruciata* Crossewort, but because I find two other herbes neere in forme thereunto, and it may be in property also, as the taste may induce one to thinke, I have placed them together.

1. *Cruciata vulgaris.* The common Crossewort.

The common Crossewort groweth up with square hairy browne stalkes, little above a foote high, having foure small broad, and pointed, hairy, yet smooth not rugged yellow greene leaves, growing at every joynt each against other crossewise, which hath caused the name; towards the toppes of the stalkes at the joynts, with the leaves in three or foure rowes upwards stand small pale yellow flowers, after which commeth small blackish round seed, foure for the most part set in every huske, the roote is very small and full of fibres or threds, taking good hold of the ground, and spreading with the branches a great deale of ground, which perisheth not in the winter, although the leaves die downe every yeare, and spring againe anew.

2. *Cruciata minor lutea.* Small yellow Crossewort.

This small plant is like the other, but smaller, and not hairy, having smooth pale greene leaves, with yellow flowers.

3. *Cruciata minor montana.* Small Crossewort with blush flowers.

This small Crossewort (for so I take it to be rather then *Gallium* as *Columna* entituleth it) hath divers square weake branches, lying at the first upon the ground, but afterwards raising themselves up on high, and spreading many branches full of joynts, and foure leaves usually at them, the lowest very small and short, but those that grow more upwards to the middle of the stalkes, are larger and longer, and from the middle upwards much longer, and towards the tops but two leaves, long and narrow standing at a joynt, which joynts are more separate one from another then below, all of them smooth, and not hairy at al, as the stalkes are likewise: the flowers stand at the toppes of the branches, in a thinne or sparsed umbell, as the small Centory, or Saint *Iohns* wort doth, which have somewhat a long and hollow truncke, and then end in foure small leaves of a blush colour, very like for their forme, as well as for their sweetenesse, unto the flowers of the white or yellow *Iasmine* but lesser then they, and larger then any flowers of *Gallium*, after which come small rugged and somewhat crooked and long seedes, two alwayes set together, greater then those of the former, and of a yellowish colour, the roote is long and great, in respect of the plant, with divers fibres set thereat, of a brownish colour on the outside and white within.

1. *Cruciata vulgaris.* Common Crossewort.

4. *Cruciata minima muralis.*
The least Crossewort.

The least Crossewort hath many smal square stalkes, smaller at the bottome, and greater upwards, sometimes reddish and somewhat hairy also, set full of joynts, and at every one of them, foure small leaves, one against another, in manner of a crosse; from those joynts likewise upwards, come forth the flowers, of a pale greene colour, consisting of foure leaves, but set in such a manner that they are scarse to be discerned from the threds, that stand with them, for one part seemeth to be a body or belly, with prickes thereon, another a head shewing to be prickly also, but not hurting, and the rest which are as it were beards, seeme to be armes, which when they are withered, seeme to be hooded: after they are past come small heads, or swelling round vessels, which were the bellies of the flowers, wherein is contained small round yellowish seede like Pannicke seede, the taste of the whole plant is somewhat bitter and harsh withall, the roote is as small almost as a thred with some small fibres at it.

The Place.

The first groweth in many moist grounds, as well medowes as untilled places about *London*, in the Church yard at *Hampsteed* neere *London*, at *Wye* in *Kent*, at *Rande*, and neere *Ringmore* in *Sussex*, along the high way, and in sundry other places. The second groweth under the hedges about *Bononia*. *Fabius Columna* saith that the third groweth in the open hils in *Naples*, and the last in the ruines of the walls of *Diocletian*, his baths in *Rome*, and some other places thereabouts.

The Time.

They are all in flower from *May* all the Sommer long, in one place or another, as they are more open to the Sunne, and the seede ripeneth soone after.

The Names.

It hath no Greeke name that we know, being unknowne to the ancients; it is called in Latine *Cruciata*, and *Crucialis*, of the situation of the leaves, as I said before, and so doe most other writers. *Thalius* calleth it *Cruciata herniaria*,

herniaria, and *Lobel Cruciata minor*, to distinguish it from the *Gentiana cruciata*. *Lugdunensis* calleth it also *Aspe-rula Aurea*, and *Tragus* maketh it his second kind of *Gallium*, for his *Cruciata* is *Gentiana cruciata*. *Bauhinus* calleth it *Cruciata hirsuta*, the *French* call it *Croise*, the *Germans Golden Waldtmeister*, the *Dutch Croysette*, and wee in English Crosswort and Golden Crosswort. The second *Bauhinus* in his *Prodromus* describeth by the name of *Gallium latifolium glabrum*, but in his *Pinax* he calleth it *Cruciata glabra*: The third *Columna* calleth *Gallium montanum latifolium cruciatum*, but because I thinke it doth more truly represent a *Cruciata*, by the standing of the leaves; I have called it *Cruciata minor montana*. The last *Columna* calleth *Cruciata nova Romana minima muralis*, and *Cesalpinus Crucialis minima in maritimis*.

The Vertues.

This Crosswort is of a binding and drying propertie, and is accounted as singular a good wound herbe almost as any, and is used inwardly not onely to stay bleeding of wounds, but to consolidatate them, as it doth outwardly any greene wounds, for by closing the lippes of the wound together it is quickly healed, *Camerarius* saith it helpeth to expectorate flegme out of the chest, and is good for the obstructions in the brest or stomacke, or in the bowells, or miseraicke veines, and helpeth a decayed appetite, to use the decoction of the herbe in wine: the same will serve also to wash or bathe any wound, or running moyst sore, to clense and heale it, the herbe bruised and then boyled and applyed outwardly for certaine dayes together, renewing it often, and in the meane time, the decoction of the herbe in wine taken inwardly every day, doth certainely cure the Rupture in any, so as it be not too inveterate, but very speedily if it be fresh and lately taken.

CHAP. XLVII.

Aparine. Gooſe graſſe, or Clevers.

THe herbe that is usually called Goose grasse or Clevers, is of two sorts, one which is rough, which is knowne to all; the other not rough at all, which is not so well knowne or observed by many, of which there are some varieties which I shall entreat of in this Chapter, but of a greater kind, whereof *Gerard* maketh mention, we know not of, but are sure his figure exhibited, is of a wilde Borrage, which *Lobel* calleth *Alyssum Germanicum Echioides*, as *Bauhinus* also testifieth.

1. *Aparine vulgaris*. Common Clevers.

The common Clevers hath divers very rough square stalks, not so bigge as the tagge of a point, but rising up to bee two or three yards high sometimes, if it meete with any tall bushes or trees, whereon it may clime (yet without any claspers) or else much lower or lying upon the ground full of joynts, and at every of them shooteth forth a branch beside the leaves thereat, which are usually six, set in a round compasse like a Starre, or the Rowell of a Spurre, from betweene the leaves at the joynts, towards the toppes of the branches come forth very small white flowers, every one upon a small threddy footestalke, which after they are fallen, there doe shew two small round rough seedes joyned together like two testicles, which when they are ripe, grow hard and whitish, having a little hole or hollownesse on the side, somewhat like unto a Navel, both stalkes, leaves and seede are so rough, that they will cleave to any thing shall touch them, the roote is small and very threddy, spreading much in the ground, but dyeth every yeare.

1. *Aparine Vulgaris*. Common Clevers.

Semine Coriandri succharati.

2. *Aparine levis*. Smooth Gooſe graſſe.

The smooth Goose grasse groweth like the former, but that it neither groweth so high, nor are the leaves so great, and not at all rough, or sticking to what it toucheth: the flowers are as small and white as the former, and give such like seede, but smooth also, and not rough as the former. There is another little differing from this in any other notable thing, but the seede which is rough like unto a Coriander Comfit.

3. *Aparine floribus purpureis*. Purple floured Clevers.

This kinde of Clevers is in all things like unto the former sort, except the colour of the flower, which in this is purple, as in the other it is white.

The Place.

The former sort groweth by the hedge and ditch sides in many places of the Land, and every where also in Gardens, where it is a weede of much labour to weede out, for it will rampe upon every thing groweth next unto it, and be ready to choake and spoyle it, shedding the seede if it be suffered of both sorts. The second was brought me out of *Spaine*, but the last is as great a stranger.

The Time.

These doe flower in *Iune* and *Iuly*, and the seede is ripe and falleth againe by the end of *Iuly*, or in *August*, not springing any more from the rootes, but from the shaken seede.

The Names.

It is called in Greeke Ἀπάρινη *Aparine*, and so it is in Latine also usually, but it hath divers other Greeke names, as φιλίστον and φιλατρεῖον, as *Galen* saith out of *Hippocrates*, and as *Dioscorides* saith ὀμφαλόκαρπος, not ἐμφαλόκαρπος, as it is falsely read in many copies of *Galen*, *Pliny*, *Paulus Ægineta* and *Ætius*, for ὀμφάλος not ὀμφακὸς, is *umbilicus*, and the seede is Navell fashion, whereof came the name; yet some have it ἐμπίλοκαρπος: It is called also φιλανθρωπος, *quasi hominis amans*, and φιλάνδρος for the same cause: *Pliny* calleth it *Lappa minor*, saying it is *Lappaginis species*, whereof this being one sort, is called *Asperugo*, because the leaves are rough; and the other *Mollugo*, because they are soft: but *Pliny* his words concerning *Mollugo*, seemes not to be truly expressed, as his copies extant doe declare: I have therefore thought it fitter to referre the *Mollugo* (at the least that which wee so call) unto the kinds of *Gallium*, then unto this *Aparine*, because we have a smooth *Aparine*, which is not the *Mollugo*; of which smooth *Aparine* I finde no auther to make mention but *Thalius* onely, no, not *Bauhinus* himselfe in his *Pinax*, which is an enumeration of all plants, that were eyther set forth by any other Author, or that himselfe knew or heard of: The *Italians* call it *Speronella*, the *Spaniards Presera*, and *Amor di hortolano*, the *French Roble* and *Grateron*, the *Germans Clebkraut*, the *Dutch Kleefcruyt*, and we in English Goosegrasse and Clevers.

The Vertues.

Clevers are hot and dry, *Dioscorides* saith and *Pliny* from him, that the juice of the herbe and seede together taken in wine, helpeth those that are bitten with Vipers, or the great Spider *Phalangium*, by preserving the heart from the venome; *Galen* saith it clenseth meanely and dryeth, and is of subtill parts: it is familiarly taken in broth to keepe them leane and lanke, that are apt to grow fat. *Tragus* saith, that the distilled water drunke twice a day helpeth the yellow Iaundies, and the decoction of the herbe is found by daily experience to doe the same, and stayeth Laskes and Bloody flixes; the juice of the leaves, or they a little bruised and layd to any wound, or place that bleedeth, will stanch the blood; and *Matthiolus* saith, that the juice is much commended and used to close the lippes of greene wounds, and so doth the pouder of the dryed herbe strowed thereupon, and likewise helpeth old Vlcers: being boyledwith *Axungia* and anointed, it healeth all sorts of hard swellings, or kernells in the throate; the juice dropped into the eares taketh away the paines of them: the herbe serveth well the Country people in stead of a strainer, to cleare their milke from strawes, haires, or any other thing that falleth into it.

CHAP. XLVIII.

Camphorata. Stinking Groundpinē.

THere are two or three sorts of this *Camphorata*, or stinking Groundpine which I thinke fittest to follow the former herbes, because of some resemblance in forme as well as in vertue.

1. *Camphorata major Monspelienſium.* The greater stinking Groundpine.

3. *Camphorate congener ſive Anthyllis altera Italorum.* Groundpine not stinking.

1. *Camphorata major Monspelienſium.* The greater stinking Ground Pine.

The rough or greater kind of *Camphorata* shooteth forth many slender and pliant feathered round stalkes of leaves, parted into many branches from the very ground, growing upright to be about a foote and a halfe high or more, thicke set with joynts by certaine spaces, and many very small thicke and narrow whitish greene leaves at them, round about the branches, very like unto the leaves of the *Tanariske* tree, but longer below then they are up higher, which being broken or bruised betwixt ones fingers smelleth somewhat strong, resembling *Camphire*, as many doe take it, and of a drying unsavory taste: there hath not beene eyther flowers or seede observed, but is increased by slip-

ping the branches; the roote is somewhat great, thicke and wooddy, blackish on the outside, with many fibres thereat.

2. *Camphorata minor.* The lesser stinking Groundpine.

The smaller *Camphorata*, hath many slender and weak stalks lying or bending to the ground in a compasse, with divers rundles of small long leaves, set at spaces, as in the former, of a yellow greene colour, especially towards winter, when the tops of the branches also will be reddish with some wollinesse thereon, whereon divers flowers do stand together, as it were in a tuft, consisting of five small white leaves a peece; after which rise small hard seede vessels, of the bignes of two barley cornes, wherein is enclosed very small seede: the roote is greater and longer then the proportion of the plant above ground may seeme to allow, of a reddish yellow colour on the outside, with many fibres thereat: the whole plant both leaves, flowers and seede, are of a strong and grievous sent, and of a very sharpe and quicke taste.

3. *Camphoratæ congener sive Anthyllis altera Italorum.* Ground Pine not stinking.

The other Ground Pine that smelleth not so strong as the former sorts doe, groweth upright in the same manner, with divers upright slender stalkes, and many small leaves set at the joynts, some of them being longer and some shorter then others, all covered with a small woollinesse: the flowers are very small, standing many together at the toppes of the branches, of a pale yellowish colour, and of an astringent and drying taste.

The Place.

The first groweth neare unto *Mompelier*, and *Nemausum*, especially out of the rifts and chinkes of the old walls of the *Amphitheater* there, and seldome in any other part of *France*, or *Italy* as *Pena* saith; yet *Lugdunensis* saith it prospereth better in fertile and moyst places, then in such as are barren and dry. The second groweth both in sandy dry grounds, and in rotten mooriish grounds likewise: The last groweth in many places of *Italy*, but whether naturally of that country or no, is not signified, but they there keepe it in their gardens, where most usually it is to be seene.

The Time.

All these flower very late, or not at all with us, and are very hardly preserved in the winter, being tender, comming from so hot and dry places.

The Names.

None of these plants were knowne to the antient writers, eyther Greekes, or Latines, by any the names of their herbes knowne to us now a dayes; the name *Camphorata*, is taken from *Camphora*, because the sent is thought to be so like unto *Camfire*, as divers doe imagine, but surely then it smelleth otherwise in the hotter countries then they doe in ours, for with us the former two have a grievous heady sent, yet nothing so fierce, and quicke in my judgement as *Camfire* is: *Anguillara* first, and others afterwards, as also *Pena* and *Lobel* referre the former unto the *Chamæpeuce* of *Pliny*, whereof he maketh mention in his 24. Booke and 15. Chapter, saying that *Chamæpeuce* hath leaves like unto the *Larche* tree; but *Lugdunensis* saith, that divers did rather referre this to the *Selago* of the sayd *Pliny*, mentioned in his 24. Booke and 11. Chapter, where he saith that *Selago* is like unto *Savine*: Divers also tooke it to bee the *Cneorum nigrum* of *Dioscorides*, and *Theophrastus*, but the learned of *Mompelier*, called it *Camphorata major*, and so doth *Lobel* call it *Camphorata Monspelienſium*. *Bauhinus* calleth it *Camphorata hirsuta*, when as according to *Lugdunensis* his description, the roughnesse belongeth rather to the second in the stalkes and leaves, and not unto this first. Divers also tooke it to bee *Ericæ prius genus*, a kind of Heath; others to be *Hyssopus nemorensis*, and some also to be that *Muſci terrestris genus* that *Tragus* doth set forth, by the name of *Sabina sylvestris*. Our *London dispensatorie*, or *pharmacopæia Londinensis*, in the description of *Unguentum Marciatum*, maketh *Camphorata* to be *Abrotanum*, which is utterly untrue, yet I think it may very well be the substitute or *succedanium* thereof for that oyntment: and *Lugdunensis* also saith, that divers did referre the second which he calleth *Champhorata minor Dalechampij*, to the *Chamæpeuce* of *Pliny* aforesaid: but *Bauhinus* calleth it *Camphorata glabra*, as though this were smooth, which as I sayd before is contrary: The last is called *Anthyllis altera*, by *Anguillara* and others: The learned in *Italy*, as *Lobel* in his observations saith, referre it to the second sort of *Authyllis* of *Dioscorides*; but because as he there saith it is not sweet as that second *Anthyllis* of *Dioscorides* should be, hee doth rather judge the *Iva Moschata Monspelienſium* to be the truer *Anthyllis altera*, then this *Anthyllis Italorum*. *Gerard* hath much erred in calling this *Anthyllis lentifolia*, and yet his figure doth expresse this *Anthyllis Italorum*, and not *Anthyllis lentifolia*, although his description doth. *Bauhinus* calleth it, as *Lobel* and others before him have done, *Camphoratæ congener*, & *Tabermontanus Camphorata altera*.

The Vertues.

These herbes are all of them of a drying faculty, and are very profitably used inwardly to stay defluxions from the head, that fall into the eyes, and upon the Lungs: and outwardly in bathes, to stay running humours that rest in the joynts, as the Goute, Crampes, Palsies, and Aches; it is no lesse effectuall for the Nerves and Sinewes to comfort and strengthen them, to be made into a salve or oyntment; and is availeable both in fresh wounds, and old running ulcers and sors; and therefore divers doe account it of the same propertie with Southernwood for all the purposes whereunto it is used.

CHAP. XLIX.

Coris. The faire Heath Low Pine.

THere are three ſorts of herbes called *Coris*, the one *Matthiolus* firſt ſet forth, and made knowne; the other *Honorius Bellus* of *Candy*; and *Pena* and *Lobel* ſet out the laſt; which are as followeth.

1. *Coris Matthioli.* *Matthiolus* his faire Heath Low Pine.

This ſpringeth up to the height of a foote or more, with divers hard, wooddy, reddiſh ſtalkes, full of joynts, and many ſmall and long thicke, fat leaves, ſet together at every of them, ſomewhat like unto the *Spergula*, or Francke Spurry: at the toppes of the ſtalkes, ſtand divers flowers, each of them upon a ſhort foote ſtalke, conſiſting of five or ſixe leaves, ſomewhat like unto *Hypericum*, S. *Iohns* wort: or *Ornithogalum* Starre of *Bethelem*, as *Lobel* compareth them, but of a whitiſh red colour, with yellow threds in the middle; yet *Matthiolus* and others ſay, the flowers are all yellow like *Hipericum*, ſmelling ſomewhat ſweete, the ſeede is encloſed in round heads: the roote is ſomewhat long and wooddy, with many thredy fibres thereat: this keepeth his greene leaves all the winter, but turne ſomewhat of a yellowiſh red colour towards Autumne or ſeede time.

2. *Coris legitima Cretica Belli.* The *Candye* faire Heath Low Pine.

This *Candiot* as *Bellus* ſaith, groweth to be a cubit and a halfe high in good ground, branching forth many wayes, and bearing many ſmall leaves, like unto Heath on the woody ſtalkes and branches: the flowers at the toppes, are not unlike to S. *Iohns* wort and yellow, which paſſe into ſeede encloſed in huskes like it alſo: the roote is long, ſpreading, and wooddy, abiding with greene leaves thereon all the winter.

3. *Coris Monſpelienſium.* The purple faire Heath Low Pine.

This faire Heath Low Pine, riſeth up likewiſe, with many round wooddy and reddiſh ſtalkes, not ſo high as the former, having many ſmall, long, thick, & roundiſh leaves ſet thereon, without order moſt commonly, & yet ſometimes conformable one unto another, ſomewhat like unto the great kinde of Heath: the tops of the ſtalkes are ſtored with a great ſpiked tuft or buſh, of purpliſh blew flowers, (but pale red with us) ſmelling ſomewhat ſweete, each conſiſting of foure leaves a peece, double forked as it were at the ends, two whereof that ſtand uppermoſt, are greater than the other two that are lower, which will abide long in their perfect colour, being gathered in

1. *Coris Matthioli.*
Matthiolus his faire Heath Low Pine.

2. *Coris legitima Cretica Belli.*
Candye faire Heath low Pine.

their

their prime, and each of them ſtanding in a browniſh huske, parted at the toppes into five points, and ſpotted with five blackiſh ſpots, on the outſide, wherein afterwards groweth the ſeede; which is ſmall round and blackiſh, wrapped up as it were in many coates or filmes, whoſe huskes then doe grow ſomewhat hard and ſharpe at the ends, when as before, while the flower laſted, they were not ſo: the roote is reddiſh, and hard, or wooddy, greater than the proportion of the plant ſhould ſeeme to require; giving a dye or colour, not onely to the fingers of them that touch it, but ſerveth alſo to dye linnen cloathes withall, for thoſe where it groweth naturally: this alſo abideth the winter, although the leaves are then more reddiſh than in Summer, but requireth ſome care to preſerve it with us.

The Place.

The firſt groweth in many places in *Italy*, in dry grounds and hils, as *Matthiolus* ſaith, and *Pena* ſeemeth to confirme the ſame, in giving a more exact diſcription thereof, than *Matthiolus* did: *Camerarius* ſaith it groweth by *Carara*, a Village in *Liguria*: the ſecond in *Candye*: and the laſt neere *Mompelier*, and the parts thereabouts, as *Pena* ſaith, and *Cluſius* ſaith, he found it in the dry grounds about *Salamanca* in *Spaine*, and neere the Sea alſo in *Valentia*, and by *Mompelier*.

The Time.

They flower early in the hot Countries as *Cluſius* obſerved, to be as well in *March* in ſome places, as in *May* in others; but late with us, and ſeldome doe perfect their ſeede.

The Names.

It is called in Greeke κόρις, and as *Dioſcorides* ſaith, of ſome in his time *Hypericum*, and in Latine *Coris* alſo: *ob pulchritudinem videtur dicta, nam* κόρη *virgo puellave dici potuit*, ſaith *Pena, quia tota pulchella, & perquam hilaris eſt; verum Hippocrates & antiqui,* κόρην, *id eſt, pupillam vocarunt, propter ſemen, oculi pupillæ, ſeu anteriori humori criſtallino, ambitu ſphærico haud abſimile, cujuſmodi in hac Monſpeliaca cernitur.* The firſt is called *Coris Matthioli*, by *Camerarius*, *Geſner in hortis*, *Lacuna*, *Lonicerus*, *Lobel*, *Lugdunenſis*, *Tabermontanus* and others; *Bauhinus* calleth it *Coris lutea*; the ſecond *Honorius Bellus*, in his firſt Epiſtle to *Cluſius*, calleth *Coris legitima, Ericæ ſimilis*, and conteſteth againſt *Bellonius* for that in his firſt booke of Obſervations, and 17. chap. he ſaith, that the roote of the *Coris* which he found in *Candy*, having yellow flowers, is very unpleaſant, whereby *Bellus* doth preſume that *Bellonius* did never ſee this true *Coris*, for the cauſe aforeſayd; that is, the unpleaſantneſſe of the roote, but that it was *Aſcyrum ſcilicet fœtidum* which *Bellonius* ſaw, and called it *Coris*; and therefore I alſo ſuſpect, *Bauhinus* hath not ſo rightly referred, *Honorius Bellus*, his *Coris Ingitima*, to this firſt *Coris Matthioli*, but ſhould rather have made it agree with the *Monſpeliaca*, or *Hiſpanica*, of *Lobel* and *Cluſius*, in regard of the manner of the growing and poſture of the leaves: the other is called *Coris Monſpeliaca*, by *Pena* and *Lobel* in their *Adverſaria*, and ſo alſo by *Camerarius* and *Tabermontanus*, and by *Cluſius*, *Coris quorundam*. *Bauhinus* calleth it *Coris cærulea maritima*; and ſaith that although *Cluſius* did ſuſpect that the *Symphitum peræum* of *Matthiolus*, was this *Coris*, yet aſſuredly, ſaith he, it was a differing plant, and was brought him from the ſame place, where *Matthiolus* ſaith his did grow. *Cluſius* ſaith that the *Spaniards* did call it *Pinſel* in their Language; and *Bellus* ſaith that they in *Candye* called his ſort *Orpilocorto, id eſt, herba orpilo*. I have given unto theſe, ſo well as unto the other in the laſt Chapter, ſuch fit *Engliſh* names, as I thinke are proper unto them.

3. *Coris Monſpelienſium.*
Purple faire Heath Low Pine.

The Vertues.

The *Corides* eſpecially that of *Mompelier*, is hot and bitter, and ſomewhat ſweete in ſent withall, and is very good to provoke Vrine, and womens courſes that are ſtopped, and for the ſtrangury, if the bladder be not exulcerated, if the ſeede be boyled in wine or bruiſed and drunke therein: the decoction thereof or the ſeede it ſelfe drunke, is a remedy for thoſe that have beene bitten with the venemous Spider called *Phalangium*, as alſo for thoſe that are troubled with the Goute or Sciatica, to be bathed therewith, or made into an oyle or oyntment: it helpeth alſo the ſhiverings or ſhaking fits of agues, taken with ſome Pepper: It is often uſed alſo in oyntments and ſalves, that are made to heale any old or running ſores, and to dry up the moyſture of them which hindreth their cure.

CHAP. L.

Hypericum. St. *Iohns* wort.

THE ordinary S. *Iohns* wort is well knowne at this day to many, but there are some other sorts brought to our knowledge, which *Dioscorides* and the other auncient writers, knew not of besides the *Ascyrum*, and *Androsæmon*, which are to be accounted other severall kindes thereof, but larger: each whereof shall be declared in their order.

1. *Hypericum vulgare.* Common St. *Iohns* wort.

The common S. *Iohns* wort shooteth forth browniſh, upright, hard, round ſtalkes, two foote high, ſpreading many branches from the ſides, up to the toppes of them, having two ſmall leaves, ſet one againſt another, at every place, which are of a deepe greene colour, ſomewhat like unto the leaves of the leſſer Centory, but narrower, and full of ſmall holes in every leafe, which cannot be ſo well perceived, as when they are held up to the light: at the toppes of the ſtalkes and branches, ſtand yellow flowers, made of five leaves a peece, with many yellow threds in the middle, which being bruiſed doe yeeld a reddiſh juyce like blood: after which come ſmall round heads, wherein is conteined, ſmall blackiſh ſeede, ſmelling like Roſſen: the roote is hard and wooddy, with divers ſtrings and fibres at it, and of a brownish colour, which abideth in the ground many yeeres, ſhooting a new every ſpring.

1. *Hypericum vulgare.*
Ordinary S. *Iohns* wort.

2. *Hypericum minus erectum.* Small upright S. *Iohns* wort.

This ſmall S. *Iohns* wort, is very rare to meete withall, being like the former, but that it is ſmaller, yet the leaves doe not fully anſwere the forme of the former, but are a little broader and not ſo ſharpe pointed; the ſtalkes are reddiſh and the flowers ſmaller, and not fully ſo yellow, nor give ſo bloody a colour, when they are bruiſed betweene the fingers; and ſometimes ſtand in circles at the joynts of the ſtalkes as well as at the toppes: the ſeede is reſinous as the former, and the roote long laſting alſo.

3. *Hypericum minus ſupinum.* Small creeping S. *Iohns* wort.

This other ſmall S. *Iohns* wort, differeth little from the laſt ſmall ſort, having reddiſh ſtalkes, not above an hand breadth high at the moſt, nor ſtanding fully upright, but leaning downewards, with ſmall narrow ſmooth leaves, and ſmall yellow flowers.

4. *Hypericum numulariæ folio.* Round leafed S. *Iohns* wort.

This little S. *Iohns* wort, is as ſmall an herbe as the laſt, whoſe ſmall reddiſh ſquare branches, riſe no higher than

5. *Hypericum tomentoſum major Hiſpanicum.* Great woolly S. *Iohns* wort.

it, having two leaves set one against another, at every joynt up to the toppes: and are almost round, like unto Money-wort or hearbe two pence, of a darke or sad greene on the upperside, and whitish underneath, spotted sometimes with reddish spotts and strakes: the flowers are of a paler yellow colour, than the former, but somewhat large in comparison of the plant, with divers yellow threds in the middle: the roote is small and long.

5. *Hypericum tomentosum majus Hispanicum.* Great woolly S. *Iohns* wort.

The greater woolly S. *Iohns* wort, hath divers hayrie, whitish woolly branches, lying upon the ground, and shooting forth fibres, very thicke set with such like leaves, as the Common S. *Iohns* wort hath, but hoarie, white, and woolly; at the joynts towards the toppes, and at the toppes also, stand paler and smaller flowers than in the common: after which come seede vessels like unto the other sorts, and so is the seede, and wooddy roote.

6. *Hypericum supinum tomentosum minus.* Small creeping Woolly S. *Iohns* wort.

The lesser woolly S. *Iohns* wort, is in most things like the greater, but that it is smaller, the branches having the woolly leaves, not so thicke set together, smaller and rounder than the former.

7. *Hypericum fruteſcens Americanum flore albo.* *Indian* S. *Iohns* wort, with white flowers.

7. *Hypericum fruteſcens Americanum flore albo.* *Indian S. Iohns* wort with white flowers.

The *Indian* S. *Iohns* wort, riseth up with sundry wooddy stems almost to a mans height, covered with a whitish barke, from whence spring on all sides, divers branches, set thicke with greene leaves, narrow below, and broad and round at the ends, sometimes 2 or 3 at a place, from which joynts also rise divers white flowers, made of foure leaves a peece: the leaves fall away every yeere, and rise againe in the spring, the wooddy stems abiding.

The Place.

The first foure sorts grow in woods, and copses, as well those that are shadie, as open to the sunne: the fift *Clusius* found in *Salamanca*, and *Valentia* in *Spaine*: the sixt likewise is often found in our Country; as well on dry barren grounds, as in mooriſh and wet fields: the last was brought from the North-west parts of *America*.

The Time.

They doe all flower about Midsommer, and in *July*, and some of them later, and their seede is ripe in the end of *July* and *August*, for the most part.

The Names.

It called in Greeke ὑπερικὸν *Hypericon*, which the Latines doe retaine, and yet some have called it *Fugadæmonum*, superstitiously imagining, that it will drive away devills: and some call it, *Perforata*, or *Porosa*, from the many small holes, are to be seene in the leaves: but we finde that in *Dioscorides* his time; the name *Hypericum* was given unto five severall hearbs; that is, to *Ruta sylvestris*, *Onobrychis*, *Hypericum*, *Ascyrum*, and *Coris* as in his Commentaries, is extant to be seene: and concerning this *Hypericum* also, he saith, that in his time it was called *Androsæmum* (of the bloody colour, the flowers yeeld) and *Chamæpytis* (of the resinous sent of the seede and heads) and yet all these herbes are severally described by *Dioscorides*, in severall chapters of his Commentaries. *Marcellus Florentinus*, from the Greeke word *Leucoion*, in the text of *Dioscorides*, whereunto he compareth the flowers of *Hypericum*, would thereupon interpret the flowers thereof to be white, and *Plinye* also mistaking the Greeke word in *Dioscorides*, as it is very frequent in him, where *Dioscorides* compareth the seede vessels of *Hypericum*, unto a barly corne that is somewhat long and round; he saith that the seede ripeneth at the time, when as barly is ripe. The *Arabians* call it *Reofricon*, *Reiofaricon*, and as others have it *Hensericon Nelifricon*; the *Italians Hyperico, & perforata, & herba di San Giouainni*: the *Spaniards Coraconcillo*: the *French Mille pertuis & Tourcheron*: the *Germanes* S. *Iohanskraut*, and *Hartham*: the *Dutch* S. *Iohns cruiit*, and we in *English* S. *Iohns* wort. The first is generally now adayes, by all authors taken to be the true *Hypericon* of *Dioscorides*, as both the bloody colour of the flowers, and the resinous sent of the heads, and seede thereof doe declare, being two principall notes thereof: the second is thought to be *Hypericum pulchrum* of *Tragus*, and the smaller sort of *Thalius*. I cannot otherwise thinke, but that it is also, the *Hypericum Syriacum* of *Lobel*, for such a one hath beene found in many places of this Land, with many small leaves set at a joynt, in the same manner. *Bauhinus* calleth it *Hypericum minus erectum*, as I doe in the title, yet he maketh *Lobel* his *Syriacum* to be another sort: the third is the *Hypericum exiguum* of *Tragus*, the *Hypericum minus* of *Gesner* and *Dodonæus*, *Hypericum minimum supinum Septentrionale* of *Lobel*, and the *Hypericum supinum tertium minimum* of *Clusius*, which *Bauhinus* calleth *Hypericum minus supinum, vel supinum glabrum*: the fourth is as I take it, the *Hypericum tertium* of *Tragus*, which *Bauhinus* in his *Pinax* maketh his second sort, and describeth it in his *Prodromus*, under the same name in the title: the fift *Clusius* calleth *Hypericum supinum, & tomentosum Hispanicum*, which as he saith *Iohannes Plasa* of *Valentia*, called *Ruta sylvestris* of *Dioscorides*, but *Ruellius* putteth that among the bastard names. *Bauhinus* calleth it *Hypericum supinum tomentosum majus, vel Hispanicum*, and yet maketh this to be *Lobel* his *Hypericum minimum supinum Septentrionalium*, which he referred before to the *minus vel supinum glabrum*, but it cannot be both this and that, because the one hath smooth greene leaves, and is lesser than the *Spanish* kinde, which is woolly, and so is not that: the sixth is the *Hypericum alterum tomentosum* of *Lobel*; but *Clusius* checketh *Lobel* in making this and his former *tementosum Hispanicum* to be both one. *Bauhinus* calleth it *Hypericum supinum tomentosum minus vel Monspelia-*

Mor. Speliacum, and thinke it to be the *Androsæmum album Dalechampij* of *Lugdunensis*, which I see no reason, why he should so judge, in that the figure expresseth an upright, and not a bending plant, and there is no description given of it: The last hath the name imposed upon it, as is fittest I thinke for it.

The Vertues.

S. *Iohns* wort is as singular a wound herbe as any other whatsoever, eyther for inward wounds, hurts or bruises, to be boyled in wine and drunke, or prepared into oyle or oyntment, bathe or lotion outwardly, for being of an hot and drying quality, with subtill parts, it hath power to open obstructions, to dissolve tumours, to consolidate or soder the lips of wounds, and to strengthen the parts that are weake and feeble; the decoction of the herbe and flowers, but of the seed especially in wine, being drunke, or the seed made into pouder and drunk with the juice of Knotgrasse, helpeth all manner of spitting and vomiting of blood, bee it by any veine broken inwardly, by bruises, falls or howsoever: the same also helpeth all those that are bitten or stunge by any venemous creature: And is good for those that are troubled with the stone in their kidneys, or cannot make water, and being applyed provoketh womens courses: two drams of the seede made into pouder, and drunk in a little broth, doth gently expell choller, or congealed blood in the stomack, and mesentery veines; the decoction of the leaves and seeds being drunk somewhat warme before the fits of agues, whether they be *tertians* or *quartians*, doth helpe to alter the fits, and by often using taketh them quite away; the seede is much commended being drunke for 40. dayes together, to helpe the Sciatica or Hippe Goute, Falling sickenesse and Palsie also. The herbe, that is, both the leaves, flowers and seede, steeped in wine for 12. houres, and then distilled in an ordinary Still, the water hereof being drunke with a little Sugar therein, is accounted as effectuall as any decoction or other preparation, and killeth the wormes in the belly or stomacke. The oyle of S. *Iohns* wort, eyther simple or compound, but the compound is more effectuall, is singular good both for all greene wounds, and old sores & ulcers, in the legs or elsewhere, that are hard to be cured, and is effectuall also for crampes and aches in the joynts, and paines in the veines and sinewes, and is also good for all burnings by fire, to be presently used, or the juice of the green leaves applyed; the hearbe dryed and made into pouder, is as effectuall for wounds and sores to be strowed thereon, as the oyle or juice. The simple oyle is made of foure ounces of the flowers infused in a pint of oyle Ollive, called Sallet oyle, and three ounces of white wine, for 10. or 12. dayes to bee set in the Sunne, and afterwards boyled in a *Balneo* or Kettle of seething water, strayned forth, and refreshed with new flowers, so set in the Sunne, and in the same manner boyled, strained forth and renewed the third time with fresh flowers, which after they have lastly stood in the Sunne a fortnight or more, are to be boyled in the sayd *Balneo* or Kettle of seething water, strayned forth, and the oyle, having some fine turpentine dissolved in it whiles it is hot, and so kept, is singular good for the purposes aforesayd. Like hereunto *Gerard* hath set downe away, which is, with Sallet oyle two parts, white wine and oyle of Turpentine one part, set in the Sunne, with the leaves, flowers and seedes, of S. *Iohns* wort, for 8. or 10. dayes, and boyled and renewed the third time, in the manner aforesayd. But the compound oyle is made of the simple oyle, after the last infusion being strained forth, there is added, *Dittanie* of Candy, *Gentian* or Felwort, *Cardus Benedictus*, or Blessed thistle, and *Tormentill* of each a small quantitie, and some earth wormes washed and slit, and all of them infused in the sayd oyle, and set in the Sunne, and after boyled, strayned forth, and Turpentine and oyle of Wormewood put thereto, which then is to bee reserved in some pot, or glasse close stopped, to be used as occasion doth require.

CHAP. LI.

Ascyrum. S. *Peters* wort.

OF this herbe likewise formerly there hath beene but one sort knowne, and described, but wee have two other to shew, not long since found and brought to our knowledge.

1. *Ascyrum vulgare.* Ordinary S. *Peters* wort.

This S. *Peters* wort that is most common in our land, riseth upwith square upright stalkes, for the most part, somewhat greater and higher then S. *Iohns* wort, but browne in the same manner, and at every joynt having two leaves, somewhat like those of S. *Iohns* wort, but larger, a little rounder pointed, and with very few or no holes to be seene therein, and having sometimes some smaller leaves, rising from the bosome of the greater, and sometimes a little hayrie also, as the stalkes will bee: at the toppes of the stalkes stand many yellow starre-like flowers, with yellow threds in the middle, very like unto those of S. *Iohns* wort, so that but for the largenesse and height, it is hardly by many discerned from S. *Iohns* wort, and that it giveth not so bloody a juice, being bruised betweene the fingers, having also such like seede, of as strong a resinous sent; the roote abideth long, sending forth new shoots every yeare.

2. *Ascyrum magno flore.* Great flowred S. *Peters* wort.

This other S. *Peters* wort is like the former, having a round browne upright stalke, two foote high at the least, with such like, but larger leaves and round pointed, of a paler greene colour on the upperside, and whiter underneath; the flowers that stand at the end of the stalke, are of a paie yellow colour like the other, but a good deale larger, with yellow threds therein also.

3. *Ascyrum supinum villosum palustre.* Creeping S. *Peters* wort of the Marsh.

The Marsh S. *Peters* wort is like the last in the round stalkes, but that they are woolly and soft, and stand not upright, but leaning downeward, taking roote at the joynts, having somewhat rounder pointed leaves set at the joynts, two for the most part together: the flowers are as yellow, and of the same bignesse as the ordinary, but give not that red juice that they doe; and these things make the whole difference from the former besides the naturall place.

4. *Ascyroides cretica major.* Great S. *Peters* wort of *Candy*.

This differeth from the former onely in the largenesse of the leaves and flowers, which are foure times bigger then it.

The

Ascyrum vulgare. Ordinary S.Peters wort.

The Place.

The first groweth in many Groves, and small low Woods in divers places of this Land, as in *Kent*, *Huntington*, *Northampton*, and *Cambridge* shires; as also neare water courses in other places: The second was found on the *Pyrenian* hills: The third in the Marshes of the Low Countries, and the last in *Candy*.

The Time.

They doe all flower in *Iune* and *Iuly*, and the seede is ripe in *August*.

The Names.

It is called in Greeke ἀσκυρὸν, and ἀσκυροειδὴς, *Ascyrum* and *Ascyroides*, *& contrario dictum putatur: σκύζ & enim asperitatem illis significat*: The Latines have no other name then *Ascyrum*, from the Greekes to call it. *Dioscorides* saith, it was also called *Androsæmum*, and *Hypericum* too, and *Galen* therefore accounteth it a kind of *Androsæmum*. The first is usually called by most writers *Ascyrum*, as *Matthiolus* doth; it is probable to bee the first *Hypericum in dumetis nascens* of *Tragus*, and is the first *Androsæmum* of *Fuchsius*, and by *Dodonæus* set for *Hypericum*, in his French Edition, but called *Androsæmum alterum hirsutum*, by *Fabius Columna*, who yet doubted whether to call it *Hypericum* or *Androsæmum*, saying it came neare unto *Ascyrum*, although somewhat differing from it (which it may bee is but the soyle and climate) *Bauhinus* calleth it *Androsæmum hirsutum*: the next two have their names in their titles that *Bauhinus* giveth them; yet the third is called by *Clusius*, in the *Auctuarium* of his other Appendix, *Ascyrum supinum* ἐλώδης: the last is called by *Alpinus lib. de exoticis*, as it is in the title; all nations christned take it as another kind of S. *Iohns* wort, and so call it, and we S. *Peters* wort.

The Vertues.

It is of the same propertie with S. *Iohns* wort, but somewhat weake, and therefore more seldome used; the seede to the quantitie of two drams taken at a time, in Meade or honyed water, purgeth, saith *Dioscorides*, *Pliny*, and *Galen* chollericke humours, and thereby helpeth those that are troubled with the Sciatica, or paine in the hippes: the leaves are used as S. *Iohns* wort, to helpe those places of the body that have beene burnt with fire.

CHAP. LII.

Androsæmum. Tutsan, or Parke leaves.

ALthough our Tutsan be not the right *Androsæmum* of *Dioscorides*, *&c.* yet because it is so generally called, and accounted by most, let it receive his place here among some other plants called *Androsæmum*, by divers writers, that thereby you may see and know the difference betweene them.

1. *Androsæmum vulgare.* Common Tutsan or Parke leaves.

Our Tutsan hath not square but browniſh shining round stalkes, crested all the length thereof, rising to be two, or sometimes three foote high, branching forth even from the bottome, but more thinly set or farther asunder, having divers joynts, and at each of them two faire large leaves standing, but more thinly set then of the other sorts, which are of a darke blewish greene colour on the upper side, and of a yellower greene underneath, turning reddish towards Autumne, but abiding on the branches all the winter: at the topes of the stalkes and branches stand larger yellow flowers, then in any of the former sorts, and heads with seede likewise larger, which being greene at the first, and afterwards reddish, turne to be of a blackish purple colour, when they are through ripe, with small browniſh seede within them, and then yeeld a reddish juice or liquor, of a reasonable good sent, somewhat resinous, and of an harsh or stipticke taste, as the leaves also and the flowers bee, although much lesse, but doe not yeeld such a cleare Claret wine liquor, as *Gerard* following *Dodonæus* therein, saith it hath; the roote is browniſh, somewhat great hard and wooddy, spreading well in the ground.

2. *Androsæmum Matthioli.* *Matthiolus* his Tutsan.

This Tutsan (for other Englisſh name I know not well, what it may have, unlesse you would call it a great S. *Iohns* wort, because it is so like it) hath browniſh round stalkes, with two leaves at every joynt, fuller of branches, else very like unto S. *Iohns* wort, but more sparingly or thinly set thereon, much smaller and greener then the former Tutsan, and greater then those of S. *Iohns* wort, without any hoales at all in them; the flowers are yellow likewise, and greater then they, and so are the heads with seede, but spotted with blacke streakes on them:

them: the roote is browniſh and abideth, yet the ſtalkes periſh; the leaves hereof as well as flowers, doe give a red juice like S. *Iohns* wort, whereof it may beſt be diſcerned, but becauſe S. *Peters* wort doth the like alſo, therefore divers doe miſtake one for another; and the rather, for that S. *Peters* wort is found to have a round ſtalke, although ordinarily it be ſquare.

3. *Androſæmum alterum Apulum.* Tutſan of *Naples.*

This Neapolitane Tutſan is more buſhie, but groweth not ſo high as the laſt, for it ſendeth forth from a reddiſh roote, ſomewhat threddy, reddiſh, or browniſh round ſtalkes, not much above a foote high, with two creſted ſtrakes like filmes all the length of them, and are full of branches, with two leaves at every joynt, ſo cloſely ſet thereunto at the bottome, that the ſtalkes ſeeme to runne through them, and yet are leſſer then the laſt recited Tutſan, ſharpe pointed, of a freſher greene colour, and ſmooth on the upper ſide, white underneath, and having many ſmall holes therein, almoſt not to bee perceived, and for the moſt part are greater and broader towards the toppes then they are below; the flowers at the toppes of the branches are of a paler yellow colour, many more ſet together then in the other, whoſe greene huskes wherein they ſtand have blackiſh ſpots on them, which ſo abide when the leaves are full of ſeede: both leaves and flowers yeeld a blooddy or reddiſh juice, being buiſed betweene the fingers, as any of the other doe.

4. *Androſæmum fœtidum.* Stinking Tutſan.

This ſtinking Tutſan groweth upright with hard wooddy ſtalkes, three or foure and ſometimes unto five cubits high, as great as ones arme below, and of a reddiſh colour, branching forth upwards with divers wings of freſh greene leaves ſet thereon, two at every joynt, ſomewhat like unto thoſe of Licoris, and doe alwayes a-

1. *Androſæmum Vulgare.*
Tutſan or Parke leaves.

2. *Hypericum maius ſive Androſæmum Matthioli.*
Matthiolus his Tutſan.

4. *Androſæmum fœtidum.*
Stinking Tutſan.

bide

bide on the branches, winter as well as Summer, in the warme countries, wherein it is naturall, but doth hardly endure our cold climate, although kept and defended with all the care wee can use: at the ends of the stalkes stand yellow flowers, like the common Tutsan, upon slender but longer foot-stalkes then in any of the former sorts, and the yellow threds in the middle of them longer also; which after they are past yeeld round and somewhat long heads, like unto the berries of the Turpentine tree, never falling away from the bushes of themselves, wherein lye very small seede. In *Candy* it yeeldeth a liquid Rosen or Turpentine that smelleth strong, more like a Goate then any Rosen, even as the leaves and all the rest of the plant doth, this yeeldeth no red or blooddy juice at all, as the true *Androsæmum* and *Ascyrum* doe.

The Place.

The first groweth in many Woods, Groves and wooddy grounds, as Parkes and Forrests, and by hedge sides, in many places of this land, as in *Hampsted* Wood, by *Raily* in *Essex*, in the wealde of *Kent*, and many other places needeless to recite: The second is found also about *Bristow* and *Bath*, and in other parts of the West country. The third *Fabius Columna* saith hee found on the hills *Cirinolæ*, which are to the Southward in *Naples*: And the last *Honorius Bellus* saith, groweth by the brookes and springs of waters in *Candy* and no where else; but it groweth upon Mount *Baldus* as *Pona* saith in the description thereof.

The Time.

They all flower later then S. *Iohns* wort, or S. *Peters* wort, and the last later then any of the other.

The Names.

It is called Greeke ἀνδρόσαιμον *Androsæmon a sanguine humano cui comæ succus assimilatur. Galen* saith it was of two sorts, the one whereof was called *Dionisias* by some in his time, the other *Ascyrium*, and *Ascyroides*. The first is called by *Dodonæus Androsæmum*, and so it is also by *Camerarius*, *Gesner in hortis*, and *Lugdunensis*, and taken by *Cæsalpinus* to be the true *Androsæmum* of *Dioscorides*, *Galen* and *Pliny*, and the *Centeria* of *Theophrastus*; but *Lobel* in his *Adversaria* contesteth against it, & saith it is the *Clymenum Italorum*, as *Anguillara* doth, and likewise *Gesner* in *hortis*, so also *Castor Durantes*, and of the *Italians* in many places called *Siciliana*, or *herba Siciliana*, because as they imagined it grew no where naturally but in *Sicily*; or *Cæciliana* as *Camerarius* hath, who also calleth it *Climenum non Dioscoridis*, *sed Plinianum*, as *Anguillara* before him did. *Bauhinus* calleth it *Androsæmum maximum frutescens*. We call it properly in *English* Tutsan, from the *French* who call it *Toutsaine*, & not from the *Italians* who call it *Tutisan*, as *Camerarius* saith. Some also call it Parke leaves, because it is so familiar to Parkes and Woods, that it almost groweth no where else. The second is called *Androsæmum* by *Matthiolus*, as also by *Fuschius*, *Lacuna*, *Cordus* upon *Dioscorides* and *Gesner*; *Camerarius* as I take it calleth it *Androsæmum minus*, for he calleth the former *majus*, and *Lobel* calleth it *Androsæmum magnum*, and *Excellentius*, because he was not perswaded that the first was worthy the name of *Androsæmum*. *Dodonæus* would have it to bee *Ruta Sylvestris* of *Dioscorides*, and thereupon calleth it *Ruta Sylvestris Hypericoides*, because *Dioscorides* writeth, that the *Ruta Sylvestris* was called *Hypericum* by some in his time; I take it to be the *Hypericum secundum Tragi in dumetis nascens*; as also to bee the *Androsæmum Campoclarense* of *Columna*. *Bauhinus* doth impose two severall names upon this herbe in my judgement, when as it is but one, for hee calleth that of *Matthiolus*, *Cordus*, *Gesner*, and the rest, *Ascyrum sive Hypericum bifolium glabrum, non perforatum* and the other of *Lobel*, which *Dodonæus* called *Ruta syl. Hypericoides*, *Androsæmum alterum foliis Hyperici, quod aliquibus Hypericoides*. The third is called by *Columna*, as it is in the title, but by *Bauhinus Androsæmum perfoliatum & perforatum*. The last is called by *Camerarius Androsæmum minus sive angustifolium* βαγώδωον, and taketh it to be *Tragium* of *Honorius Bellus* of *Candy*, called by the inhabitants *Neroicti*, as hee saith, and as it is remembred by him, in his third Epistle to *Clusius*, set forth with *Clusius* his *Historia rariorum plantarum*, whose figure as *Camerarius* thought, was not as then set forth by any; but since his time *Bauhinus* hath exhibited the figure thereof in his *Matthiolus*, by the name of *Androsæmum fœtidum*, and afterwards by *Pona*, in the description of mount *Baldus*, both in his Latine and Italian Edition, when he calleth it *Tragum legitimum veterum, ab ipso Bello effigiatum*, and in the same Latine Edition, fol. 11. hee calleth it *Tragium Creticum Belloni non Dioscoridis*, and so doth *Bauhinus* also: but I thinke *Bauhinus* was mistaken, to thinke that this plant, which in his *Pinax*, he formerly referreth to *Tragium* of *Honorius Bellus*, should bee also the same with *Ascyrum Legitimum*, for *Bellus* saith, that the *Cretans* called this *Agoudouro*, and the *Tragium Neroicti*, as it is before sayd, so that these are two severall plants, and called by two severall names, as *Bellus* sheweth it, who was so singular in herbarisme, that he would not fall into such an errour as *Bauhinus* here doth.

The Vertues.

Tutsan moderately heateth and dryeth, yet the seede hath an absterfive qualitie, whereby it purgeth choloricke humours, as S. *Peters* wort is sayd before to doe, for therein and in all other things it makes the same effect, both to helpe the Sciatica and Goute, and to heale burnings by fire: it stayeth also the bleeding of wounds, if eyther the greene herbe bruised, or the pouder of the dry be applyed thereto; it is, and so hath formerly in all ages among husbandmen, beene accounted a soveraigne herbe to heale any wound or sore, eyther outwardly or inwardly as the name importeth; and therefore it was alwayes one of their singular good herbes wherewith they made wound drinkes, or lotions, Balmes, oyles, or oyntments, for any sort of greene wound, or old Vlcers and sores, in all which the continuall experience of many ages, to bee admirable good, hath confirmed the use thereof to be assured, although it be not so much in request and use as formerly it was, when as Chirurgions and leeches did more addict themselves to use herbes, then now they doe.

CHAP. LIII.

Bupleurum. Hares eares.

MAny have reckoned the *Bupleura* fit to be placed with the *umbellifers*, because they beare tufts of flowers and seede like unto them, but in that their growing is much different; I have thought it fitter to speake of them apart.

1. *Bupleurum anguſtifolium* Narrow leafed Hares eares.

The narrow leafed Hares eares, riſeth up with a round ſtiffe greene ſtalke two foote high; at the ſeverall joynts whereof, grow ſeverall long and narrow very darke greene ſhining ſmooth leaves, broadeſt at the bottome, and narrower by degrees unto the ends, with divers ribbes running thorough them, the middlemoſt whereof is greateſt, yet nothing ſo narrow as graſſe leaves, as divers doe compare them, as any that I have ſeene of this ſort, which ſtand one above another up to the top, growing ſmaller and ſmaller, at the joynts likewiſe; from the middle of the ſtalkes at the leaſt, upwards if it grow in any good ground, come forth ſmall branches, but ſometimes with few or no branches at all, at the tops whereof ſtand many ſmall tufts or umbells of yellowiſh flowers, which turne into ſmall ſeede, like Parſeley ſeede, but of a darker colour, and ſomewhat longer; the roote is ſomewhat long, but ſmall, and white on the outſide, like unto a Parſley roote, with divers fibres thereat, periſhing yearely with me, as the next alſo.

2. *Bupleurum latifolium.* Broad leafed Hares eares.

This other Hares eares groweth in the ſame manner that the former doth, with ſtalke, branches, flowers, ſeede, and roote, and herein chiefly if not onely differeth from it, that it beareth broader and ſhorter leaves, ſmalleſt at the foote, broadeſt in the middle, and ending in a ſmall point, ſomewhat hollow, and bowing downewards with divers long Nerves or ribbes therein, as in the former, and the middle moſt eminent, or raiſed higheſt.

3. *Pupleurum Anguſtifolium Alpinum.* Mountaine narrow leafed Hares eares.

This mountaine Haires eares, from a round thicke roote, about a foote long ſet with knobs or bunches inſtead of branches, and with a thicke barke, of a darke red on the outſide, and pale within, divided at the head into many parts, ariſe divers long and narrow greene leaves, lying on the ground, compaſſing one another at the bottome like a ſtarre, for the forme of them like unto the firſt Hares eares, but narrower: from divers of theſe tufts of leaves, ariſe darke round ſtalkes, about an handbreadth high, bearing at the toppes many pale yellow flowers, made of ſeaven pointed leaves a peece, and in the middle of them divers ſmall ſeed ſet thicke together, ſomewhat like unto the Thorowwax, ſet forth in the next Chapter, or as the former Haires eares, which ſmell very ſtrong; the whole plant elſe, taſteth like an Artichoke.

4. *Bupleurum minimum.* The leaſt Hares eares.

The leaſt Hares eares, is alſo like the firſt deſcribed hares eares in all things, the ſmalneſſe of the plants, both in ſtalkes, narrow long leaves, and all other partes making the difference.

The Place.

The two former *Lobel* ſaith grew about Mompelier in *France*, in the dry ſtony places, and in *Germany*, as *Tragus* ſaith, and are alſo found in our Land, in divers places: the third upon Mount *Baldus*, as *Pona* in the deſcription thereof ſaith: the laſt *Columna* ſaith he found in the borders of the dry fields, neare *Cirinola* in *Naples*.

The Time.

They all flower late, that is not untill the end of *July*, and in *Auguſt*, and their ſeede is ripe in *September*.

2. *Bupleurum Latiſolium.*
Broad leafed Hares eares.

3. *Bupleurum anguſtifolium Alpinum.*
Mountaine narrow leafed Hares eares.

The

The Names.

It is generally taken to be the Βούπλευρον *Bupleurum*, that *Pliny* mentioneth in his 22. booke, and 22. chap. out of *Hippocrates*, and *Nicander in Theriacis*; and was as he there saith, used in meates in *Hippocrates* his time and others, and reckoned among sallet and pot herbes, but used in Physicke and medecines, by *Glaucus* and *Nicander*. Divers have diversly referred these herbes, as some to the *Bupreſtis* of *Theophraſtus*, in his 7. booke, and 8. chap. whereof *Pliny* also speaketh, in the sayd booke, and chapter before sayd: *Geſner in hortis* saith, that with the *French*, it was called *Elaphoboſcum* and *Gratia Dei*. Some also tooke it to be the *Panax Chironium*, of *Dioſcorides*, some to be *Ammi vulgatius*, and some *Sanamunda*. *Bauhinus* in his *Pinax* saith, that *Panax Chironium Plinii* doth more rightly agree unto the *Valeriana campeſtris ſive lactuca agnina*, Lambes Lettice, or Corne sallet: those about *Mompelier* as *Geſner in hortis* and *Lobel* say, called it *Auricula leporis*, especially the *Latifolium*, for the resemblance thereof unto Hares eares. *Cordus* in his history of Plants, calleth it *Hſophyllon*. *Tragus* calleth it *Herba Vulneraria*, *Woundkraut*, not understanding from any of his nation, by what other name they called it, and therefore he himselfe referreth it, to the *Panax Chironium* of *Theophraſtus*, who saith it hath the leafe of a Docke, but that of *Dioſcorides* & *Nicander* have the leaves of *Amaracus* or Marjerome. I finde a great mistake, and forgetfulnesse in *Bauhinus* as well as in *Lugdunenſis*, this in setting forth, and he in admitting the errour to passe concerning the *Bupleurum* which *Lugdunenſis* calleth *Lapathum ſylveſtre 4: genus Dalechampii* in one place, and *Bauhinus Lapathum acutum flore aureo*, and yet *Lugdunenſis* saith there, that some called it *Panaces Chironium folio Lapathi flore aureo Plinij*, which was sufficient I thinke, to make him understand it to be this *Bupleurum*, and not a *Lapathum*; and yet both he & *Bauhinus* in their proper places, call it *Bupleurum* notwithstanding. The third is called by *Pona*, in his Latine edition of Mount *Baldus*, *Sedum petræum Bupleurifolio, aut potius Bupleurum petræum gramineo folio*; but *Cluſius* in setting forth the description of the sayd Mount *Baldus*, giveth it this note, that it is *flore verius, quam folio Bupleuri*. *Bauhinus* in the sayd Latine edition of *Pona*, is set downe to call it then *Bupleurum Alpinum, Bupleurifolio* (which I have thought fittest to follow, as it is in the title; but afterwards in his *Pinax*, hee referreth it to the *Perfoliata*, calling it *Perfoliata Alpina gramineo folio, ſive Bupleurum anguſtifolium Alpinum*, hereby judging the *Perfoliata* and *Bupleurum* to be *congeneres*, for in the heads of seede, the one is somewhat like the other, as any that hath seene them both may well observe. *Fabius Columna* maketh mention of the last, and calleth it, as it is in the title: and *Bauhinus Bupleurum anguſtiſſimo folio*.

The Vertues.

These herbes are moderately hot and dry, and therefore may well be accounted *Panaces*, or Wound herbes, and have the same properties that they have, and which *Pliny* and others attribute unto *Bupleurum*: if the seede or the roote in powder taken in wine, or boyled in wine be drunke; and so are the leaves also good against the bitings, or stingings, of any serpents or venemous creatures, the hurt place also bathed with the same, and is of great efficacy to provoke Vrine, and womens courses being stopped: they are also to very good purpose, either used alone, or with other things, to heale wounds inward or outward, whether they be fresh and greene, or old cancres and sores, of evill disposition, and bad curation.

CHAP. LIIII.

Perfoliata. Thorough waxe.

THere are divers sorts of Thoroughwaxe, some greater, some lesser, some of the fields and Meddowes, other of the hils and mountaines, &c. al of neere affinitie one unto another; and with them I thinke fit to joyne another herbe, which some have referred to another family, because of the long cods with seede that it beareth.

1. *Perfoliata vulgaris.* Common Thoroughwaxe.

The common Thoroughwaxe, sendeth forth one straight round stalke, and sometimes more, two foote high and better, whose lower leaves being of a blewish greene colour, are smaller and narrower than those up higher, and doe stand close thereto, not compassing it, but as they grow higher, they doe more and more encompasse the stalke, untill it wholly as it were passe through them, branching toward the toppe into many parts, where the leaves grow smaller againe, every one standing singly, and never two at any joynt: the flowers are very small, and yellow, standing in tufts at the heads of the branches, where afterwards grow the seede; small and blackish, many thicke thrust together: the roote is small, long, and wooddy, perishing every yeere, after seede time; and rising plentifully of it owne sowing, if it be suffered to shed it selfe.

2. *Perfoliata flore multiplici.* Double flowred Thoroughwaxe.

This differeth in nothing from the former, but in the heads of flowers, which are thicker set together, and larger, which give no seede, but is wholly a degenerate kinde, rising from the seede of the former, spending his fruite and encrease in the plentifull heades of flowers.

3. *Perfoliata montana latifolia.* Broad leafed Mountaine Thorough waxe.

The leaves of this Mountaine throughwaxe, are somewhat larger and longer, and more pointed than the former, many growing together, from the heads rising from the roote, every one standing on a small foote-stalke; from among which rise up stalkes with shorter leaves, which compasse the stalkes, that are branched at the toppes, whereon stand yellow flowers, somewhat larger than the former, many in like manner set together, in the midst of the under greene leaves, which are as a cup to conteine them, wherein afterwards stand the seede, like the former but larger: the roote is thicke and reddish on the outside, lying long wise under the face of the ground, shooting forth heads of leaves in divers places, and with small strings and fibres downeward, enduring many yeeres, and not perishing like the former. *Bauhinus* maketh another sort hereof with smaller flowers, yet giveth no description thereof. *Minor.*

4. *Perfoliata Alpina latifolia minor.* The lesser broad leafed Mountaine Thoroughwaxe.

This lesser Throughwaxe is somewhat like the first or common sort, but that it is smaller, rising not so high, and bearing on the stalkes such like leaves but smaller, which are divided at the bottome of them into two parts, the stalkes so passing through them, but are not whole and round as the former are, and branching at the toppes,

1. *Perfoliata vulgaris.*
Common Throughwaxe.

3. *Perfoliata montana latifolia.*
Broad leafed mountaine Throughwaxe.

4. *Perfoliata latifolia minor.*
The lesser broad Mountaine leafed Throughwaxe.

9. *Perfoliata siliquosa vulgaris seu Brassica campestris.*
Common codded Throughwaxe.

whereout from betweene two leaves, come forth ſuch like pale yellow flowers, ſtanding in tufts, with ſmall ſeede following like it alſo: the roote is ſmall and reddiſh, periſhing as it doth.

5. *Perfoliata Alpina anguſtifolia major.* The greater narrow leafed Mountaine Thoroughwaxe.

This greater Mountaine kinde of narrow leafed Throughwaxe, hath divers very long, and narrow, whitiſh greene ſmooth leaves, ſpread on the ground, about a foote long, of an inch, or inch and halfe broad, with corners alſo about them almoſt like Ivie leaves, which compaſſe the ſtalkes about the bottome of them, ſeldome more than one at a joynt; at the toppe whereof come forth five broad leaves ſtanding round, from the midſt whereof ariſe ſixe or ſeven ſmall ſtalkes, ſome longer and ſhorter than others, bearing thereon ſmall reddiſh yellow flowers, in the middle of ſmall round leaves: the roote is long and thicke, covered with a blackiſh barke, and endureth.

6. *Perfoliata Alpina anguſtifolia minor.* The leſſer narrow leafed Mountaine Thoroughwaxe.

This Thoroughwaxe hath but one ſtalke, about a foote high, without any branches bearing thereon at ſeverall diſtances, long and narrow leaves like the laſt, but ſhorter and leſſer, compaſſing the ſtalke at the bottome, and at the toppes ſome few reddiſh flowers, ſtanding in tufts like the common kinde, and ſeede accordingly: the roote is ſmall and reddiſh.

7. *Perfoliata Alpina anguſtifolia minima.* The leaſt narrow leafed Mountaine Thoroughwaxe.

This leaſt kinde is a ſmall plant, not paſt an hand breadth high, with a reddiſh running or creeping roote, ſhooting forth in divers places very narrow, long, ſmooth, greene leaves: from among which ariſeth a ſtalke, parted into two branches and each of them againe into other ſmaller ones, with one or two leaves under them, compaſſing them at the bottome, where it is broadeſt: the flowers are ſmall, and yellow, ſtanding together in tufts like the other.

8. *Perfoliata minor ramis inflexis.* Small Thoroughwaxe with bending branches.

This ſmall Thoroughwaxe hath divers leaves, ariſing from the roote, which are ſomewhat long, but ſhorter than thoſe of the firſt Mountaine Thoroughwaxe: the ſtalke is ſmall, and lyeth as it were upon the ground, bearing ſuch like leaves as that Mountaine kinde doth, and compaſſing the ſtalke in the ſame manner: the flowers are yellow like the common kinde: the roote periſheth every yeere like unto it, and therein differeth from moſt of the other mountaine kindes.

9. *Perfoliata ſiliquoſa vulgaris.* Common codded Throughwaxe.

The ordinary codded Thoroughwaxe, hath weake ſtalkes, branching forth at every joynt, with leaves ſet at them, compaſſing them at the bottome, very like unto the firſt Common Thoroughwaxe, but thicker, fatter, and more pointed, and of a whiter greene colour, moſt like unto Cabbage or Colewort leaves, and with ſquare unevenneſſe on the edges uſually: the toppes of the branches are furniſhed with many ſmall white flowers, ſtanding one above another, conſiſting of foure leaves a peece, which afterwards turne into ſmall long and ſquare coddes, wherein is conteined round browniſh ſeede: the roote is ſmall and wooddy, periſhing after ſeede time.

10. *Perfoliata ſiliquoſa flore purpureo.* Codded Thoroughwaxe with purple flowers.

This other codded Throughwaxe, is very like the laſt, having ſtraighter, and more upright ſtalkes, and larger flowers thereon, of a pale purpliſh colour, like unto thoſe of the white Sattin: in all the reſt it differeth not from the laſt.

The Place.

The firſt, and the laſt ſave one are found oftentimes in our owne Land in many corne fields, and paſture grounds: the ſecond, as I ſayd, is but a degenerate kinde of the firſt, and is often found in gardens, where the firſt is ſowen: the 3. 4. 5. 6. 7. 8. grow all upon hills, ſome in *Germany*, and the Alpes of the *Switſers*, and ſome upon the *Apenins* towards *Spaine* and *France*: the laſt alſo aſwell as the ninth *Cluſius* ſaith, he found in a Province of *Spaine*.

The Time.

They doe all flower about *Iuly*, and their ſeede is ripe in *Auguſt*.

The Names.

It tooke the name of *Perfoliata* (for there is no ancient Greeke, or Latine author, hath written of it) from the growing of the ſtalkes through the leaves, yet ſome have thought it to be the *Cacalia* of *Dioſcorides*, and ſome would make it his firſt *Cotyledon*, but neither of them agreeth with it. *Cæſalpinus* taketh it to be his *Seſeli Æthiopicum*, which differeth much from this: all the later writers doe generally call it, *Perfoliata*, and *Perfoliatum*: the *Italians* call it *Perfoliata*: the *French Perſefueille*, and the *Germanes Durch wachſs* and ſo the *Dutch* alſo: in *Engliſh* Thoroughwaxe or Thoroughleafe: the ſecond is expreſſed by *Camerarius in horto*, as alſo the third from *Geſner*, who firſt ſet out the exact figure thereof, being the firſt Mountaine kinde here, and is the *Perfoliata longifolia Dalechampij* in *Lugdunenſis*, although it may ſeeme much to differ from it in ſhew: the fourth I take to be the *Perfoliata altera* of *Lugdunenſis*, whereof it is likely alſo *Camerarius in horto*, maketh mention under the name of *Perfoliata minor*, and it may be *Bauhinus* remembreth it, under his *Latifolia minor*: the fift *Bauhinus* maketh his *Perfoliata Alpina anguſtifolia major*, and he maketh another like unto it, which he calleth *Media*, and thereunto referreth the *Perfoliata longifolia Dalechamphii* of *Lugdunenſis*, when as I can finde no other *Perfoliata* in him; whereunto the *montana* is to be referred, but there is ſo little difference betweene his *major* and *media*, that I take them both for one; the greatneſſe of the one from the other, being likely to be cauſed onely by the climate, and ſo his *major* may as well agree unto that of *Dalichampius*, as his *media*: the ſixth alſo *Bauhinus* calleth *Perfoliata Alpina anguſtifolia minor*, and is very like the *Bupleurum Alpinum anguſtifolium*, ſet forth in the former chapter, yet he giveth a caution, that they ſhould not make them both one: the ſeventh hee calleth *minima*, but diſtinguiſheth it from the *Perfoliata minima Bupleuri folio* of *Columna*, which he ſaith alſo is *Odontitis lutea* of *Lugdunenſis*: but I cannot otherwiſe think then that his *minima* is *Columna* his *minima*, alſo and likely to be the *Seſeli Æthiopicum parvum* of *Cæſalpinus*: the eighth is remembred onely by *Bauhinus* in his *Pinax & Prodomus*: the ninth is called *Perfoliata ſiliquoſa*, or *Napifolia Anglorum ſiliquoſa*, by *Lobel* in his *Adverſaria* and Obſervations, and as *Tragus*, *Geſner*, *Camerarius*, *Tabermontanus*, and all or moſt of the Herbariſts at this time doe: although divers other, from the colour of the leaves, and forme of the flowers and ſeede, would referre it to the wilde Coleworts, and thereupon call it *Braſſia campeſtris (ſylveſtris & agreſtis) ſiliquoſa* or *perfoliata*; but

Lobel in his *Adversaria* saith, it partaketh of the Navew, (and therefore calleth it, as is before said, *Perfoliata Napifolia*) and Winter Cresses, as well as of the Throughwaxe, or *Perfoliata siliquosa*: the last *Clusius* calleth *Brassica campestris altera*, or *purpureo flore*, but as I did referre the other, so I doe this, and call it *Perfoliata siliquosa flore purpureo*.

The Vertues.

Thoroughwaxe is hot and dry, and therefore of singular good use with Chirurgions, for all sorts of bruises and wounds, either inward or outward, and old ulcers and sores likewise, if the decoction of the herbe made with water or wine be drunke, and the places washed therewith, or the juyce or greene herbe, bruised and boyled, either by it selfe, or with other herbes, in oyle or *Axungia*, to be made into an oyntment, to serve for all the yeere: the decoction of the herbe, or the powder of the dryed herbe, taken inwardly, and the same or the greene leaves bruised, and applyed outwardly, is no lesse singular and availeable to cure ruptures and burstings, especially in children, before it grow to be too old, the successe still answering the commendations of it: being applyed also with a little flower and waxe, to childrens navels that sticke forth, doth helpe them. *Tragus* saith that the codded Throughwaxe, is of the same operation with the other, and worketh the like effects, for his second *perfoliata* or *minor* hath long cods, which can be no other than this, although in *Camerarij horto*, it be mistaken, and *major Tragi*, set for *minor*, for so *Gesner in hortis* hath it.

CHAP. LV.

Pimpinella sive Sanguisorba. Burnet.

Pimpinella hath a double interpretation declaring two sorts of herbes, for it either signifieth Burnet, and then it is usually also called *Sanguisorba*, or it is referred to the Saxifrages, and then it is called *Pimpinella Saxifraga*, Burnet Saxifrage, of either of which kindes there are diverse sorts: but of the Saxifrage kindes, because they are umbelliferous plants, I shall speake among the other of that rancke or order, and of these Burnets in this place, whereof there is both greater and lesser, and in either of both some difference; and although I have set forth the common Burnet in my former booke, yet because I there spake of it, onely as an herbe for a Kitchen garden, and spake very little of the properties; I thought good to mention it here againe, and enlarge the vertues.

1. *Pimpinella vulgaris sive minor.* Common Burnet.

The common Ordinary Burnet groweth with many long winged leaves, spread upon the ground, which consist of divers small roundish leaves, greene on the upper side and grayish underneath, finely dented about the

1. *Pimpinella vulgaris sive minor.* Common Burnet.

3. *Pimpinella major vulgaris.* The ordinary great Burnet.

edges,

edges, ſet on each ſide of a middle ribbe; among which riſe up creſted browne ſtalkes, two foote high or better with ſome ſmaller leaves, ſet in ſome places thereon, divided into ſundry branches, and at the toppes ſmall round looſe heads, or knaps upon long foote ſtalkes, of a browniſh colour; from whence ſtart forth ſmall purpliſh flowers, and after them cornered ſeede: the roote is ſmall, long, and blackiſh browne on the outſide, growing downe deepe into the ground, with ſome fibres thereat: the herbe hath a fine quicke ſent and taſte, giving a delicate reliſh unto wine.

2. *Pimpinella minor inodora.* Vnſavory Burnet.

This unſavory Burnet is in all things like the former, but that the leaves of this are not ſo round, but ſomething longer, and have neither ſent or taſte in them to commend it like the other.

3. *Pimpinella major ſive ſylveſtris.* Great or wilde Burnet.

The great wilde Burnet hath ſuch like winged leaves riſing from the rootes, but nothing ſo many, and each of theſe leaves on the wings, are twiſe as large at the leaſt, as the other; and nicked in the ſame manner about the edges, of a grayiſh colour on the underſide: the ſtalkes are greater and riſe higher, with many ſuch like leaves ſet thereon, & greater knaps or heads at the tops, of a browniſh greene colour, and out of them come ſmall darke purple flowers, like the former, but greater: the roote alſo is blacke and long like the other, but greater: this hath in a manner neither ſent or taſte therein, like the common ſmall, or garden kinde.

4. *Pimpinella maxima Americana.* Great Burnet of *America.*

This great Burnet is in all the parts thereof like the laſt, but much greater, having oftentimes all the leaves, which are of a blewiſh greene on the upperſide, and folded halfe way together inward, the underſide of the leaves, which are grayiſh, ſhewing themſelves upward, nicked ſomewhat deepely about the edges, with greater dents, which make them ſhew the more comely, and gracefully: the toppes of the ſtalkes carry ſmaller, and much longer, whitiſh greene ſpiked heads, ſet thicke with knaps, each whereof when it flowreth (beginning below and ſo riſing higher) ſheweth to be foure whitiſh greene leaves, having many ſmall white long threds in the middle: after which come the ſeede in the ſame places, being cornered like the other: the roote is much greater and wooddy, longer alſo and blacker than the laſt: this hath little ſent, but in taſte is ſomewhat like the firſt, yet nothing ſo aromaticall.

The Place.

The firſt groweth wilde in divers places of this Land, in dry ſandy places, but is uſually preſerved in gardens, to be ready at hand, when it ſhall neede to be uſed: the ſecond was found in *Spaine*, as *Bauhinus* ſaith: the third is found in divers Countries of this Land, eſpecially in *Huntington* and *Northampton* ſhires, in the Meddowes there, as alſo neere *London* both by *Pancras* Church, in two or three fields nigh unto Boobies barne, as alſo by a cauſie ſide in the middle of a field by *Paddington*: the laſt was brought out of the North parts of *Virginia*, where it is naturall.

The Time.

All theſe flower about the end of *Iune*, and beginning of *Iuly*, and their ſeede is ripe in *Auguſt*.

The Names.

The Greeke word πιμπινέλλα or as *Geſner* hath it πεμπινέλλα *Pimpinella*, is onely found in *Nicolaus Myrepſus*, and is thought by divers to be underſtoode of this hearbe, (for it is not knowne to be mentioned by that name, in any of the old writers: but divers by good judgement doe referre it to the *Sideritis ſecunda* of *Dioſcorides*, whereunto it anſwereth fully, both in forme and qualities, ſo that we neede not any further to doubt thereof, and the rather, becauſe as it is ſayd at this day, this herbe is called *Sideritis* by the Greekes, in the Iſland *Chio*, or *Sio*, divers alſo referre his *Sideritis* unto the other kindes of *Pimpinella*, that are umbelliferous, for there is ſuch a confuſion among many of the later writers, that it is hard to underſtand, which of theſe two kindes they meane whereof they write: *Geſner in hortis Germaniæ*, maketh mention of *Pimpinella minor ſativa lævis*, to be of the ſame kind with the other *ſylveſtris*, or wilde ſort, & as he ſaith, not differing from it, but in the manuring, which his *Pimpinella minor ſylveſtris*, is the Saxifrage kind as may be plainly perceived, by his own words following: for he ſaith that that herbe which the *Germanes* call uſually *Pimpinella* is by other people called *Saxifraga*, and by the *Italians Hircina*, or *Pimpinella hircina*, and yet *Bauhinus* maketh this *Pimpinella ſativa lævis* of *Geſner*, to be *Sanguiſorba minor lævis*, which is quite contrary to his mind as I think; and although by ſaying it is uſed in ſallets, he might ſeeme to underſtand this Burnet kinde, which was wont often to be ſo uſed, yet his words of *Saxifraga Hircina*, cannot be underſtood of this Burnet, but of the other *Saxifraga umbellifera*: the like doubt and difference there is concerning thoſe ſcarlet berries, that grow upon the rootes of *Pimpinella vulgaris* (as *Fragoſus* maketh mention, *l.* 3. *c.* 15. which he taketh to be the *Coccheniłla*, for he there ſaith, that *Cochenille* is a certaine berry brought from *Peru*, which groweth upon certeine ſmall plants, like unto *Pimpinella vulgaris*, unto whoſe rootes it doth ſticke, of the likeneſſe of wilde Grapes, which ſome take to be the true *Coccognidium*, and others to be the *Chermes* of the *Arabians*, which differeth from the *Coccus Baphica* of the *Graciens*; thus ſaith *Fragoſus*; all which is utterly untrue,

untrue, for *Cochenille* is neither the berry of any *Pimpinella*, nor is it the true *Coccognidium*, nor doth the *Chermes* of the *Arabians* differ from the *Coccus Baphica* of the *Græcians*, as shall be shewed in due place, but *Oviedus* truly saith that *Cochenille* groweth like berries on the underside of the leaves of a tree in the West Indies called *Tunal*, or by others *Tunas*, which tree we call *Ficus Indica*. Now whether of the two kinds of *Pimpinella* is meant, this or that is not expressed, for some referre it to one and some to the other. Some as it should seeme call *Pimpinella*, *Pampinula*, and *Peponella*, but I rather referre all these names to the Saxifrage kindes: it is called *Sorbastrella*, and *Sanguinaria* also of divers, but most usually *Sanguisorba*, *quod sanguineos fluxus sistat* and it may be *Bipinella* or *Bipennula*, *a foliorum binis ordinibus pennatim sive plumatim digestis*: the *Italians* call it *Pimpinella* or *Sorbastrella*, the *French Pimpinelle*, the *Germanes Hergots bertlin* (*id est*, *Dei Barbula*) *Blutkraut*, and *Megelkraut*, because the country people as *Tragus* saith, give it to their Hennes, and Geese when they have the Pippe, to cure them of it; we doe in all places I thinke in England call it Burnet: but many of our ignorant Apothecaries doe shamefully mistake this herbe, in using *Pimpernell* in their Syrupe of *Dealthea*, and in other their medecines instead thereof, from the neareneſſe of the Latine and English names, of *Pimpinella* and *Pimpernell*, taking them to bee both one: it may be referred also as it is thought to that herbe which in *Persis* is called *Sistiepteris*, as *Pliny* saith in his 24. Booke and 9. Chap. because it causeth mirth, and *Dionisionymphas*, because it doth wondrously well agree with wine. The first is called *Pimpinella Sanguisorba*, to distinguish it from the other *Pimpinella Saxifraga*, and *Pimpinella minor* and *hortensis*, to distinguish it from the other *Sanguisorba*, which is called *major*, and *sylvestris*: *Anguilara*, *Guilandinus*, *Tragus*, and *Columna*, call it *Sideritis secunda Dioscoridis*, and so doe others since them: they also call it *Pimpinella Italica*, and is the first of *Tragus* by that name, for the third is his *Pimpinella Italica major*, and so (*Lusius* calleth it also: others call it *Pimpinella sive sanguisorba major*, and *Columna Sideritis* 2. *Dioscoridis major*. The second *Bauhinus* onely mentioneth, and the last is not remembred by any writer before me, although *Lobel* may seeme in his *Adversaria* to point at this, where he saith, that the great wilde kind hath sometimes leaves as great as Betony, as this hath, but yet is not this, being a differing kind, as by the heads of flowers may well be knowne.

The Vertues.

Both the greater and the lesser Burnet are accounted to be of one property, but the lesser, because it is quicker and more aromaticall, is more effectuall being both hot and dry in the second degree, especially the lesser (yet some say it is cold in the second degree) which is a friend to the Heart, Liver, and other the principall parts of a mans body; two or three of the stalkes with leaves put into a cup of wine, especially Claret, as all know give a wonderfull fine rellish to it, and besides is a great meanes to quicken the spirits, refresh the heart, and make it merry, driving away melancholly: it is a speciall helpe to defend the heart from noysome vapours, and from the infection of the Plague or Pestilence, and all other contagious diseases, for which purpose it is of great effect, the juice thereof being taken in some drinke, and they either layd to sweate thereupon, or wrapped and kept very warme. They have a drying and astringent quality also, whereby they are availeable in all manner of fluxes of blood, or humours, to stench bleeding inward or outward, Laskes or Scowrings, the Blooddy flix, womens too aboundant courses, and the whites also, and the chollericke belchings, and castings of the stomake, and is also a singular good Woundherbe, for all sorts of wounds, both of the head and body, either inward or outward, for all old Vlcers, or running Cancers and moyst sores, which are of hard curation, to bee used eyther by the juice or decoction of the herbe, or by the pouder of the herbe or roote, or the water of the distilled herbe; or else made into oyle, or oyntment by it selfe, or with other things to be kept: the seede also is no lesse effectuall, both to stay fluxes and to dry up moyst sores, to be taken in pouder inwardly in steeled water or wine, that is wherein hot gadds of steele have beene quenched, or the pouder of the seede mixed with their oyntments, or injections.

Chap. LVI.

Sideritis sive Ferruminatrix. Ironwort.

HAving in the last Chapter shewed you that Burnet is the second *Sideritis* of *Dioscorides*, I thinke it not amisse to entreate next thereunto, of some other herbes called *Sideritides*, as being referred by many authors unto the first kinde of *Dioscorides*, leaving the third sort to bee spoken of in another place hereafter.

1. *Sideritis prima Herba Iudaica.* Iewes Ironwort.

This first *Sideritis* is a small low herbe, neither wholly standing upright, nor wholly leaning downe to the ground, but hath divers weake, rough, hoarie square stalkes not much above a foote high, full of joynts, at the severall distances whereof, grow two small leaves somewhat long, rough, or as it were crumpled, hard and hairy, not halfe so broad as Horehound leaves, dented about the edges, smelling and tasting somewhat strong, which spread abroad into divers branches, the upper parts whereof are repleniſhed, with many rough small wharles of pale purplish gaping flowers, with hoary leaves at the joynts under them also; where after they are past, come small blackish seede, conteined in those huskes, wherein the flowers stoode before: the roote is small and woody, yet living and shooting forth a new every spring.

2. *Sideritis parva procumbens.* Small Iewes Ironwort.

This small herbe is somewhat like the former in the hairy square branches, but more trayling or leaning, and in the leaves, but somewhat larger, a little hairy, and dented from the middle of them forwards: the flowers stand compassing the stalkes at certaine distances as the others doe: the roote is small and perisheth every yeare.

3. *Sideritis altera parva Clusij.* Another small Iewes Ironwort.

This other small Ironwort hath the middle stalke upright somewhat hairy and square, spreading into many smaller branches, even from the bottome upwards, which in a manner lye on the ground, with two such like leaves as the last at the joynts, but little or nothing dented at all; the flowers are white, without spots, as farre as I remember, but gaping in like manner: the roote of this likewise perisheth every yeare.

4. *Sideritis*

1. *Sideritis prima Herba Iudaica.*
Iewes Ironwort.

2. *Sideritis parva procumbens.*
Small Iewes Ironwort.

4. *Sideritis vulgaris Cluſij.*
The Germanes Ironwort.

5. *Sideritis Monſpelienſis Lobelij.*
Small Ironwort of *Mompelier.*

4. *Sideritis vulgaris Cluſij.* The *Germans* Ironwort.

This Ironwort that is moſt common in *Germany*, as *Cluſius* ſaith, groweth greater and higher then the other, with larger, hairy, rough, pointed leaves, ſet by couples one againſt another, at the joynts of the ſquare hairy ſtalkes, dented about the edges, but ſet at farther diſtances; which branching themſelves forth, are ſet from the middle upwards, with many wharles of gaping white flowers at the joynts with the leaves, ſpotted with blood red ſpots in the upper part of them, ending in a long ſpike, the ſeede that followeth is ſmall, uneven and blacke, contained in five ſquare heads: the roote is white and wooddy, ſhooting new ſtalkes every yeare.

5. *Sideritis Monſpelienſis Lobelij.* Small Ironwort of *Mompelier.*

The ſmall Ironwort of *Mompelier* riſeth ſcarſe to a foote heigh,

heigh, having many ſquare hoary upright hard ſtalkes, whereon are ſet at the joynts two long leaves, as hairy, hoary, and crumpled as the firſt Iewes herbe, and as deepely dented about the edges: the tops of the ſtalkes and branches have many wharles of flowers ſet in rough huskes, like thoſe of Savory, in ſome of a purpliſh colour, in others of a yellowiſh purple.

6. *Sideritis montana Hyſſopifolia.* Mountaine Ironwort.

This mountaine Ironwort hath ſlender round ſtalkes, lying upon the ground, and ſhooting forth rootes at the joynts, as they lyeth thereon, ſet with ſmall long and narrow leaves on them, like unto thoſe of Hyſſope, very thinly by couples, and ſometimes more growing out betweene them, leſſer then they: the flowers are of a pale purpliſh colour, of the ſame faſhion with the other, and ſet in ſuch rough huskes: the roote is long crooked and hard.

7. *Sideritis montana Apula verſicolor.* Mountaine Ironwort of *Naples*.

The Neapolitane Ironwort riſeth up with a reddiſh, ſquare, hoary and hard hairy ſtalk, a foote and a halfe high, divided into two branches, about the middle thereof, whereon are ſet at the joynts, two ſmall and long pale greene leaves one againſt another, covered with an hoary downe, and having three dents or notches on each ſide at the ends of them, which at the lower end of the ſtalke next the ground, have long footeſtalkes under them, but up higher at the top are without any: the flowers ſtand in ſharpe pointed huskes and are gaping or hooded as the reſt are but very ſmall, whoſe head and jawes are of a darke purpliſh colour; the middle of the flower is yellow, and the long necke of the flower that riſeth out of the huske is whitiſh: after the flowers are paſt, come foure blackiſh aſhcoloured ſeede, ſomewhat cornered in the hairy or hoary huskes, the roote is ſmall hard and yellowiſh.

8. *Sideritis Germanica parva.* Small *Germany* Ironwort.

This ſmall Ironwort hath low ſquare ſtalkes of a foote high, branched from the very ground, being ſoft and hoary as the leaves are alſo that ſtand by couples, being long and ſomewhat narrow without any dents at all about the edges, yet larger below then above: the branches have flowers growing about them upwards as ſoone almoſt as they ſhoote out, in ſhape as the other ſorts are, but they are ſo ſmall, that they ſcarſe appeare out of the huskes, of a duskie colour; the jawes and lower part on the inſide being whitiſh: after which come blackiſh ſeede ſmaller then in the other; the roote is white and wooddy, and periſheth every yeare.

9. *Sideritis foliis Alſines Triſſaginis.* Ironwort with Germander Chickweede leaves.

This Ironwort ſhooteth forth a ſquare hairy ſtalke a foote long, ſpread into branches from the bottome, and thoſe againe ſending forth other ſmaller ones, all of them enclining to the ground, like the Germander Chickweede, but much greater, whereon ſtand a few hairy leaves by couples, in forme like unto that Chickweede alſo but larger, and dented about the edges: the flowers grow at the joynts with the leaves towards the tops, like unto the other in faſhion, but ſomewhat longer, and of a blewiſh colour ſtanding in ſharpe and rough huskes, wherein ſmall round ſeede ſucceedeth, the roote is ſmall and threddy.

6. *Sideritis montana Hyſſopifolia.*
Mountaine Ironwort.

8. *Sideritis Germanica parva.*
Small Germany Ironwort.

10. *Sideritis*

10. *Sideritis Quernofolio.* Ironwort with Oaken leaves.

The ſtalke of this Ironwort is ſtraight, and with few branches, bearing very ſparſedly ſomewhat broad and round pointed leaves, unevenly cut in on the edges, ſet upon ſhort footeſtalkes by couples, which are ſomewhat like unto one of the kinds of Oake: the flowers are ſmall, and ſtand in ſmall rundles about the toppes, of a pale purpliſh colour.

11. *Sideritis Hederulæ folio.* Ironwort with Alehoofe leaves.

This is a ſmall herbe not much above an handbreadth high, beating ſmall, broad and roundiſh greene leaves with round dents about the edges, like to Alehoofe, or rather unto the red Archangell leaves: the flowers are hooded ſmall and purpliſh, and the ſeede ſmall and blackiſh: the roote is ſmall and threddy, periſhing every yeare, but raiſing it ſelfe from it owne ſowing aboundantly enough in a garden where it hath beene once ſowen.

12. *Sideritis glabra oblongo ſplendente folio.* Ironwort with ſmooth long leaves.

This Ironwort hath ſquare and joynted ſtalkes, ſmooth below, but with ſome ſmall hairineſſe at the toppe: the leaves are ſmooth and thinne, ſet by couples, the lowermoſt three inches long, and one broad, not dented at all about the edges: the flowers are hooded like the common ſort, but white, larger then they and longer alſo, ſtanding in rough huskes about the ſtalkes, even from the bottome almoſt, after which come ſmall blackiſh uneven ſeede, in heads like Plantaine but ſhorter.

13. *Sideritis arvenſis rubra.* Meddow Ironwort with red flowers.

The roote of this herbe is very fibrous or full of threds, from whence riſeth up a ſquare browne ſtalke, full of branches, and thereon divers narrow long and pointed rough leaves, ſomewhat dented about the edges, ſet by couples, at the toppes whereof ſtand the flowers, compaſſing them as the others doe, of a carke red colour, and ſometimes of a white colour: the whole plant is of an auſtere or harſh binding taſte, without ſmell, and periſheth every yeare.

14. *Sideritis arvenſis latifolia glabra.* Broad leafed meddow Ironwort.

This other medow Ironwort hath larger ſmooth greene leaves below then thoſe above, a little dented about the edges, the ſquare ſtalkes are branched, and the flowers in ſome purpliſh tending to white, in others of a pale or yellowiſh white, ſet in coronets or circles about the ſtalkes, without any ſent as the others alſo.

15. *Sideritis Anglica ſtrumoſa radice.* Clownes Woundwort.

As a Complement to theſe *Sideritides*, let me adde this Woundwort as laſt of all, though not the leaſt in effect, which from a countrey mans experience, hath not onely obtained the name of a Woundwort, but famouſed to poſteritie, for others to receive good alſo thereby, which elſe might have beene buried with him that healed himſelfe therewith of a cut with a Sithe in his Legge. It growethup ſometimes to three or foure foote heigh, but uſually about two foote, with ſquare greene rough ſtalkes but ſlender, joynted ſomewhat farre aſunder, and two very long and ſomewhat narrow darke greene leaves, bluntly dented about the edges thereat, ending in a

11. *Sideritis Hederæ folio.*
Ironwort with Alehoofe leaves.

15. *Sideritis Anglica ſtrumoſa radice.*
Clownes Woundwort.

long

long point: the flowers ſtand towards the tops, compaſſing the ſtalkes at the joynts with the leaves, and end likewiſe in a ſpiked top, having long and much open gaping hoods, of a purpliſh red colour with whitiſh ſpots in them, ſtanding in ſomewhat rough huskes, wherein afterwards ſtand blackiſh round ſeede; the roote is compoſed of many long ſtrings, and ſmaller fibres, with ſome tuberous long knobbes growing among them, of a pale yellowiſh or whitiſh colour; yet at ſome times of the yeare theſe knobbie rootes in many places are not ſeene in the plant; the whole plant ſmelleth ſomewhat ſtrongly.

The Place.

Many of theſe are ſtrangers in England, growing ſome in Medowes, others on Mountaines; yet ſome are naturall to our Country, beſides the laſt which groweth in ſundry countries of this Land, as in *Middleſex* neare *London*, by the path ſides in the fields going to *Chelſey* and *Kenſington*, by *Hackney* in the ditch ſides of a field called the ſhoulder of mutton field, and in *Surry* in S. *Georges* fields, and in the Medowes by *Lambeth*, and under that tree by Stangate, over againſt *Weſtminſter* bridge, which ſtandeth alone upon the banke and none elſe: in *Kent* by Southfleet, and on the backſide of the Church yard of *Nettleſteede*, hard by Sir *Iohn Scots* houſe, and in the middle of the next field to the Lime Kilne, at the foote of ſhooters hill. In *Wilton* towne in the very ſtreete, neare a place called the *Maudline*: in *Eſſex* by the ditch ſides, and on the ditches ſides on the left hand of the high way beyond *Stratford Bow*. In *Suffolke* alſo, *Cambridge* and *Huntington* ſhires more plentifully.

The Time.

They all flower in *Iune* and *Iuly*, and their ſeede is ripe ſoone after.

The Names.

Σιδηρίτις in Greeke, *Sideritis ſic dicta a ferro, quaſi Ferruminatrix, quod vulneribus ferro factis fuit medela*, for that it did heale wounds made by the ſword, whereof there was great uſe in the warres, and therefore many herbes that were conducing to this purpoſe, although of different formes were called *Sideritid s*, as alſo *Stratiotes*, as *Dioſcorides*, *Pliny* and others doe declare (becauſe *milites* Souldiers had moſt ſpeciall uſe of them) in Latine alſo *Sideritis* and *Militaris*, who have mentioned divers ſorts. The firſt ſort here expreſſed is thought by moſt Herbariſts, to be the right *Sideritis prima*, or *Herculea Dioſcoridis, ſic dicta propter vires planè Herculeas* (and in *Germany* the French ſort is ſo accounted and called alſo:) the reſt ſet forth in this place are referred thereunto, as *ſpecies* of the ſame *genus* and moſt neare, and like thereunto, both in forme and qualities; (otherwiſe all the herbes ſet downe in this Claſſis, and many other might be called *Sideritides*, being they are *Vulneraria*, Woundherbes for that purpoſe:) It is alſo called *Tetrahil*, *Tetrahit*, and *Herba Iudaica* by divers, becauſe the Iewes that exerciſed Phyſicke and Chirurgerie, like the Charletones and Mountebankes in *Italy*, and the Quackſalvers in *Germany* had this herbe in much uſe with them; the ſecond and third of mine here, are the fourth and fift of *Cluſius*: the fourth is the firſt of *Cluſius*, which he calleth *vulgaris*, becauſe it was beſt knowne and moſt familiar to the *Ge manes* growing amongſt them. The fift is called by *Lobel* and *Pena* in their *Adverſaria*, *Sideritis Monſpeliaca Scordioides*, and in his *Icones plantarum*, is ſet *floribus luteis*, *Tragoriganum praſſioides Franciſci Pennini*: it is alſo the fift *Sideritis herbariorum* of *Tabermontanus*, which *Bauhinus* calleth *Sideritis foliis hirſutis profunde crenatis*: the ſixt is called by *Lobel* and *Pena* *Sideritis montana*, and is the ſeventh ſort of *Cluſius*, and the ſixt of *Tabermontanus*, which *Bauhinus* calleth *Sideritis Alpina Hyſſopifolia*: the ſeventh is by *Columna* called *Sideritis montana parvo flore nigro purpureo*: the eight is the ſixt *Sideritis* of *Cluſius*, which hee ſaith is familiar at *Vienna*, as his firſt and my fourth is alſo. The ninth is by *Bauhinus* ſo called as it is in the title: the tenth is by *Lugdunenſis* ſo called, and *Bauhinus* followeth him, and withall ſaith, that ſuch a like Plant he gathered in *Padoa* garden, by the name of *Brittanica*: the eleventh is of mine owne endeavours finding it wilde, and planting it in my garden, where it hath continued ever ſince: the twelfth is by *Bauhinus* onely ſet forth in his *Pinax* and *Prodromus*, which he had from *Sprengerus* of *Heidelberg*: the thirteenth is called *Ladanum ſegetum* by *Lugdunenſis*, who ſaith ſome alſo called it *Tetrahit anguſtifolium*: *Camerarius* calleth it *Sideritis arvenſis flore rubro*, and *Thalius*, another *congener* to his firſt; *Cæſalpinus* *Sideritis alia in vineis*: *Tabermontanus* *Alyſſium Galeni flore purpureo*, and *Bauhinus* *Sideritis arvenſis anguſtifolia rubra*. The foureteenth is the *Sideritis ſecunda Matthioli*, as *Bauhinus* ſaith, although *Lobel* thinketh it to be a kind of *Cannabis ſpuria*, and others take it to be *Cluſius* his *Marrubium Pannonicum*: it is the *Sideritis Heraclea altera* of *Cæſalpinus*, the *Sideritis arvenſis flore pallido* of *Camerarius*, the *Sideritis arvenſis ſpecies altera* of *Thalius*, ſet downe by *Gerard*, & *Tabermontanus* under the name of *Alyſſum Germanicum*; and called by *Bauhinus* *Sideritis arvenſis latifolia glabra*: The laſt is called by *Gerard* *Panax Coloni*, from a country husbandmans cure of his owne Leg therewith, which he had cut in mowing downe a field of Peaſe; but why he ſhould call it *Panax* in Latine, being not an herbe for all diſeaſes, nor like unto any knowne *Panax* in forme, I know not, unleſſe *Quicquid in buccam venerit*, he tooke that which came next to hand, for in my judgement it is a differing *Sideritis* from any before, and therefore I have given it the title *Sideritis Anglica ſtrumoſa radice*, for the cauſes ſet downe in the deſcription. It may ſeeme probable to many that this herbe was not onely knowne to divers of our moderne writers, but called alſo *Sideritis* by ſundry of them, for it is ſuppoſed to be *Thalius* his firſt *Sideritis*, which he termeth *gratis admodum odoris*, *Camerarius* his *Stachys paluſtris Geſneri*, *Geſner* himſelfe calling it *Betonica fœtida & Herbæ Iudaicæ cognata*, underſtanding thereby the *Sideritis* or *Tetrahil* that was moſt common amongſt them, and with *Lugdunenſis Chymenum minus*; but I ſtand in ſome doubt thereof; firſt in that the leaves of theirs are ſhorter then of this, then that the flowers are ſayd to bee pale purple, and ours are very rêd, ſpotted with white: their rootes likewiſe are not deſcribed to have any tuberous knobbes at them. except *Thalius*. The *Arabians* call the *Sideritides* in generall *Sidrachi*, the *Italians* *Siderite*, the *French* in ſome places as I heare, *L'herbe Carpentaire*, the *Germans* *Glidkraut*, the *Dutch* *Glidernijt*, and wee in Engliſh after the Dutch name, Glidewort of ſome, and Ironwort of moſt, for Woundwort is too generall a name, unleſſe you will the clowne to it as *Gerard* doth.

The Vertues.

Moſt of theſe herbes are very powerfull to ſtay all Fluxes of blood, in man or woman, inwardly or outwardly, as alſo to ſtay rheumes and defluxions from the head, but eſpecially the firſt, the fourth, and the laſt: the firſt and the fourth being neareſt in forme and alſo in qualities, being of ſpeciall uſe for the ſoure and choller icke belchings of the ſtomacke, and to heale burſtings or ruptures, and the whites in women as well as the reds; for being exceeding drying and binding, and moderately hot, as wee take it, (yet *Galen* ſaith of halfe cold

and

and moyſt, and but a little bending) it not onely preſerveth thoſe parts, but is admirable good for all greene wounds, to ſtay the bleeding, and to heale and cloſe up their lippes quickely without ſuppuration, as well as to dry up the moyſture and fluxe of humors in old fretting ulcers, and cancres, that hindreth their healing; and herein as it ſeemeth, it hath his name *Heraclea*, by priviledge of excellency, as an *Hercules* or maſtertamer of the ſtrong: and if there be any inflammation about the parts, by the application of the herbe, juyce or decoction, it is ſoone taken away. The laſt by *Gerard* his teſtimony of the uſe thereof is ſingular effectuall in freſh wounds, and can be no leſſe availeable in the ſtaying of blood and humors than the others.

CHAP. LVII.

Alyſſum. Madwort.

THis name *Alyſſum* is diverſly confounded, both by the ancient and moderne writers, being referred to divers herbes, for *Dioſcorides* hath one ſort, and *Galen* another, and *Pliny* a third, each differing from others, as it is thought, and *Matthiolus* hath a kinde of *Thlaſpi*, for the *Alyſſum* of *Dioſcorides*, and others as *Lobel* ſaith, the *Bugula* or *Conſolida media*, *Ruellius* a kinde of wilde or Baſtard Hempe, *Cæſalpinus* taketh that kind of Horehound, that is called *Cardiaca* Motherwort, to be *Alyſſum Galeni*, and *Fracaſtorius* our ordinary Clary, *Geſner* and others take *Aſperula*, or ſome other ſmaller Madder to be *Pliny* his *Alyſſum*, and *Cæſalpinus Cruciata*: but be-cauſe they are all improperly applyed, I meane not here to entreate of any of them in this place; but of other plants, that this later age hath found out, moſt neerely to repreſent the two ſorts of *Dioſcorides* and *Galen*, their *Alyſſum*.

1. *Alyſſum Dioſcoridis.* The Madwort of *Dioſcorides*.

The Madwort of *Dioſcorides*, hath many hoary, hard, and rough leaves, lying on the ground, ſomewhat broad and round, for the firſt yeare of their ſpringing, but the next yeere when the ſtalke beginneth to ariſe, they grow thereon both greater and longer, and ſomewhat torne in on the edges, in ſome places, which ſtalke is hoary about a cubite high, and ſpreadeth into two or three branches, at the toppes whereof come divers pale yellow, and very ſmall flowers ſtanding one above another ſeverally, on both ſides of the ſtalkes, which turne into ſomewhat large and round, flat, thinne, hoary, hard, rough huskes, reſembling little bucklers; or rather moſt like the yellow huskes with ſeede, of the *Lunaria major*, or *Bolbonach*, which is the white Sattin, but that theſe are ſmaller, rougher, and harder, and wherein lye ſmall flat reddiſh ſeedes, in a double order on both ſides of the thinne middle skinne, which in this is not white, like that of the ſattin, but elſe very like: the roote is ſmall and woody, dying every yeare, after it hath given ſeede, and ſeldome periſheth the firſt yeere, before it runne up to ſtalke.

1. *Alyſſum Dioſcoridis.*
Madwort of *Dioſcorides.*

3. *Alyſſum montanum Columnæ.*
Madwort of *Columna.*

2. *Alyſſum alterum Dioſcoridis minus.* The leſſer Madwort of *Dioſcorides.*

This leſſer Madwort hath divers long leaves, lying on the ground, a little waved on the edges, of a pale or blewiſh greene colour, about three inches long and one broad, rough and hayrie, but ſofter than the former; from among which riſe ſlender weake rough ſtalkes, ſcarſe able to ſtand upright, parted into ſundry branches, whereon grow the leaves by couples, one oppoſite to another, ſmaller but not leſſe hayrie, and rough than the former, the flowers firſt beginne to breake forth at the toppes, and afterwards on the ſides or winges, which are many ſet together in tufts, conſiſting of foure white leaves, notched in the middle, which maketh every leafe ſeeme like a hurt, with divers yellowiſh threds in the middle of them, and each ſtanding in a greene huske, the outſide whereof have longer foote ſtalkes than thoſe more inward, and each flower larger than the inner ones, which being paſt; there ſucceede round ſeede veſſels like bucklers, ſmaller than the former, hard and rough on the outſide, in which are conteined flat ſeede, in foure round reddiſh cells or partitions, divided by a certaine ſhining skinne, two ſeede lying in each cell or partition: the roote is ſmall and long, with divers fibres thereat, and abideth, ſhooting forth a new, more ſharpe in taſte than the leaves, which are drying and aſtringent.

3. *Alyſſum montanum Columnæ.* Mountaine Madwort of *Columna.*

This other Madwort of the Mountaines, hath a ſmall thredy roote, from whence ſpring up ſmall and weake round reddiſh ſtalkes, lying upon the ground, ſhooting forth rootes at the joynts, and rayſing themſelves up againe, the loweſt leaves whereof are ſmall and roundiſh, not much bigger than ones naile, but thoſe that grow up afterwards upon the ſtalkes are greater, being two inches long, deepely dented about the edges, and very rough, covered with a long hairineſſe, two for the moſt part, ſet at every joynt, with long foote ſtalkes under them: at theſe joynts likewiſe on both ſides come forth three or foure blewiſh flowers, each ſtanding upon a very ſmall hayrie footeſtalke, having foure ſmall greene leaves under them as a huske wherein they ſtand, and wherein afterwards groweth the ſeede veſſels, which are two, flat, ovall or round huskes like Bucklers, joyned at the ſides together, hayrie at the brimmes, and conteining five or ſixe yellow flat ſeedes in each partition: the roote dyeth every yeere, and muſt be new ſowen, when any will have it.

4. *Alyſſum Galeni Cluſio.* *Galen* his Madwort according to *Cluſius.*

Cluſius his Madwort of *Galen* is accounted a kinde of Horehound, and riſeth up with a ſquare whitiſh woolly ſtalke, divided into branches from the very bottome, having two leaves at every joynt, ſomewhat like unto Horehound, but leſſer, rounder, and more hoary, ſmaller at the bottome, broade at the ends, and ſomewhat divided at the edges, without ſent, but bitter in taſte: at the joynts with the leaves come forth the flowers, round about the ſtalkes like unto Horehound, but of a purpliſh colour, ſtanding in hoary huskes, with points very ſharpe and prickly, wherein after they are paſt, lye red ſeede, like unto thoſe of Horehound: the roote is ſmall and ſtringie, and abideth in the warme Countries, as it is probable after it hath perfected the ſeede; for *Cluſius* ſaith he found it in *Spaine* in *March*, having both flowers and ripe ſeede thereon, but being ſowne as he ſaith, in theſe colder Countries, it every yeere periſheth, and by the ſeede which it ſheddeth is renewed againe.

4. *Alyſſum Galeni Cluſio.* *Galen* his Madwort according to *Cluſius.*

5. *Alyſſum verticillatum foliis crenatis.* Madwort with dented leaves.

This hath a ſmall wooddy roote with fibres ſet thereat, from whence riſe ſundry ſquare ſtalkes of a foote or more high, leaning down to the ground, ſet with leaves at ſundry diſtances, the loweſt being largeſt, ſomewhat like unto Horehound but longer, comming neere unto thoſe of Germander, but hoary, with a rough hayrineſſe, and dented not deepely about the edges, ſomewhat like Betony: at the joynts of the ſtalkes where the leaves grow leſſer upwards, riſe ſundry whitiſh purple flowers ſet in wharles or roundles as Horehound hath, out of prickly huskes which conteine in them browniſh ſeede: the whole herbe is in taſte aſtringent, yet not unpleaſant to the taſte, and having withall a little bitterneſſe, and ſweeteneſſe withall in ſent.

The Place.

The firſt groweth in gardens both with us, and in *Italy*, *France*, and the Low Countries, the originall place being not well knowne: the ſecond groweth about *Rome*, and the third upon one of the hils in *Naples*, as *Columna* ſaith: the fourth *Cluſius* ſaith he found in one place in *Spaine* and no where elſe: the laſt *Columna* ſaith groweth by the pathes ſides of the dry rockie hills in *Naples*, where there is ſmall ſtore of earth for it to grow in

The Time.

Theſe doe all flower about *July* and *Auguſt*, and the ſeede is ripe quickely after.

The Names.

It it called in Greeke Ἄλυσσον *Alyſſum*, and *Alyſſum* in Latine, ſo called becauſe it cureth thoſe that are bitten by a mad dog, yet *Plutarch in Symposia lib. 3. q. 1.* by ſaying it helpeth the hickock, would derive the name from λύζειν *ſingultire*. There is ſome doubt among many, whether theſe ſhould be the right or true *Alyſſa* of *Dioſcorides*

rides and *Galen*: for as concerning the first, they affirme, that it may more fitly be referred unto the sorts of *Thlaspi*, or of *Lunaria Græca*, and therefore some have called it *Lunaria major*, and *Lunaria lutea*, *Cæsalpinus Lunaria Græca tertia*, and *Gesner Lunaria aspera*; but *Dodonæus*, *Clusius*, *Camerarius*, *Lugdunensis* and *Lobel* doe all call it *Alyssum* and *Alysses*, & *Lobel* saith farther, there is no herbe to be found that better agreeth with *Dioscorides* his *Alyssum* in all things then this first doth. *Ætius* in his first booke saith, that *Alyssum* was called *Sideritis Heraclea* by some in his time, that it grew by the way sides, and bore a purple flower, and thicke leaves (which is most likely *Galens Alyssum*) some doe account it a kinde of *Leucoium*, and so do both *Columna* and *Bauhinus*; the one calleth it *Leucoium montanum lunatum*, for he saith that the *Leucoia* and *Thlaspi*, be *congeners*, which I grant, but yet I thinke, that the *Lychnides* be nearer congeners to the *Leucoia*, then the *Thlaspies* be; the other that is, *Bauhinus* calleth it *Leucoium Alyssoides clypeatum majus*. The second is called by *Columna*, *Leucoium peltatum Romanum minus*, who saith it is a congener to the *Alyssum* of *Dodonæus*, which as I sayd is the first here expressed; and therefore *Bauhinus* calleth it, *Leucoium Alyssoides clypeatum minus*. The third *Columna* calleth *Alyssum Dioscoridis montanum*: but *Bauhinus* setteth it among the *Chamædries*, calling it *Chamædrij spuriæ affinis rotundifolia scutellata*, which in my judgement is very improper, and may be set downe among the rest of his improper titles; for unlesse it bee the leaves in this plant that hath some likenesse, and that is very little, there is no part therein else that can agree with any *Chamædrys*, eyther *vera* or *spuria*; for whoever saw a *Germander* with broad bucklerlike huskes of seede: the fourth is called by *Clusius Alyssum Galeni*, and saith hee never saw any plant that came nearer to the discription of *Galens Alyssum* then this doth, and that notwithstanding that hee had read what *Columna* had written thereof, in his φυτοβάσανῳ calling it *Planta Hispanica*, *Marrubio similis*, and not thinking it to be *Alyssum Galeni*, yet he was still of the same minde: and I finde that *Camerarius*, *Dodonæus*, *Lobel*, *Tabermontanus* and *Bauhinus*, doe all follow *Clusius* herein, but none *Columna*; onely *Lugdunensis* seemeth to contrary *Clusius*, in saying that it seemed to him, that he did expresse the *Molucca spinosa* instead of *Alyssum Galeni*: the last *Columna* hath set forth in his *Phytobasanos*, calling it *Sideritis Alysson*, *Sideritis Heraclea Dioscoridis*, *Alysson Antonij Coi ex Galeno*; whereby hee seemeth to judge the *Sideritis Heraclea* of *Dioscorides*, to be all one with the *Alyssum Galeni*, and herein as it is likely confirmed, because he found *Ægineta* and *Ætius* (as I sayd before) to say that some in his time called the *Sideritis Heraclea*, *Alyssum*; yet the figure that *Columna* setteth out for it, is so like (for I have not seene his plant if it differ from) the *Herba Iudaica*, that I thinke it the very same, whereas *Dioscorides* maketh his *Sideritis* to have longer leaves then Horehound, almost as bigge as Sage, but so is not his: but the same *Columna* in another place maketh the *Alsine Veronicæ folijs* to be *Alyssum* also, *Bauhinus* entituleth it, *Alyssum verticillatum folijs crenatis*, when as he called that of *Clusius Alyssum verticillatum folijs profundè incisis*.

The Vertues.

These *Alyssa* of *Dioscorides* and *Galen*, although they differ in forme one from another, yet they doe agree as they say in this, that being taken in wine, or in broth, or in meate, or howsoever, doth cure the venome of the biting of a madde dogge, and thoroughly performe the cure, which *Galen* saith in *sexto simplicium medicamentorum*, it worketh from the likenesse of the whole substance, and was found so to doe by plaine experience, without any other method, and that it would performe many other cures if any should try it, for those diseases where the faculties of drying, digesting and moderately clensing, which are in this herbe are required; and therefore both *Dioscorides* and *Galen* doe say of each of their plants, that they clense the skinne from wheales and pimples, from spots and other discolourings, as the morphew, sunburning, &c. *Dioscorides* saith that his *Alyssum*, taken in drinke stayeth the hickocke if there be no ague, and that it will doe so also, if any shall but hold it in their hand or smell unto it: They are also effectuall for wounds, either inward or outward, to digest the clotted blood that is gathered by any fall, blow, or bruise, and to clense and heale old rotten and filthy Vlcers, or creeping Cancers. And because *Dioscorides* saith it is an Amulet to expell charmes, that shall be used upon man or beast, and that tyed with a scarlet cloth to cattell that are diseased, it helpeth them; therefore divers in the ages since, have eeked this tale with the reports of farre greater things, which because they are not onely idle but prophane, I list not to insert them here: for from the forme of the seede vessells of the first here expressed, which is that of *Dioscorides*, as I sayd divers called it *Lunaria*, Moonewort, and went beyond the Moone in expressing the properties; and therefore I thinke had neede themselves to be cured of their madnesse herewith.

CHAP. LVIII.

Vlmaria sive Regina prati. Medowsweete or Medesweete.

OF this herbe there are two sorts, the one familiar to our countrey, the other a stranger to us, and onely entertained of a few, and those the lovers of rare Plants.

1. *Vlmaria vulgaris.* Common Mede or Meddowsweete.

The stalkes of this Medesweete are reddish and easie to breake, rising to be three foote high, and sometimes to be foure or five, having at the joynts thereof large winged leaves, standing one above another at distances, which are made of many somewhat broad leaves, set on each side of a middle ribbe, being hard rough or rugged, crumpled much like to Elme leaves, whereof it tooke the name, but having also some smaller leaves with them, even as *Agrimony* hath, somewhat deepely dented about the edges, of a sad greene colour on the upperside, and grayish underneath; of a pretty sharpe sent and taste, very like unto Burnet, and will no lesse give a fine rellish to a cup of Claret wine if a leafe be put therein then Burnet; at the toppes of the stalkes and branches stand many tufts of small white flowers thrust thicke together, which smell much sweeter then the leaves; and in their places being fallen, come croked and cornered seede: the roote is somewhat wooddy and blackish on the outside, and browniish within, with divers greater strings and lesser fibres set thereat, of a strong sent, but nothing so pleasant as the flowers or leaves, and perisheth not but abideth many yeares, shooting forth a new every spring.

2. *Vlmaria major sive altera.* The greater Medesweete.

This Medesweete groweth higher then the former, with longer winged leaves set one above another upon the

1. *Vlmaria vulgaris.* Common Medeſweete.

2. *Vlmaria major ſive altera.* The greater Medeſweete.

creſted browniſh ſtalkes, having long footeſtalkes upon them, each being divided uſually into three parts, the two loweſt one againſt another, and every part alſo conſiſting of three or five ſmaller leaves then the other, ſeparate each from the other, being hard crumpled and finely dented about the edges: at the tops of the ſtalkes grow the flowers in longer ſpikes more ſparſedly and not ſo thicke thruſt together, turning downe their heads which are white like the former, and ſmelling very ſweete alſo, more nearely reſembling a Goats beard, whereof ſome have given it the name then the other: the roote is more wooddy, with many blackiſh ſtrings which ſmell ſtrong, and taſte ſomewhat harſhly: the ſtalkes and leaves dye wholly downe every yeare, and riſe againe in the ſpring.

The Place.

The firſt groweth in moyſt Meddowes that lye much wet, or neare the courſes of water, and the later is found alſo in ſhadowie woods, and places very often.

The Time.

They are found in flower, in ſome place or other all the three Summer moneths, that is, *Iune*, *Iuly* and *Auguſt* and their ſeede is ripe quickly after.

The Names.

They are not fround mentioned by any of the ancient Greekes, or Latines, onely ſome thinke it may bee referred to *Rodora* of *Pliny*. It is called by the later writers *Vlmaria*, *a foliorum Vlmi ſimilitudine*, of the likeneſſe of Elme leaves, of *Dodonæus Regina prati*, and *Barba*, and *Barbula Capræ*, or *Barba Caprina* of *Tragus*, and by him thought alſo that it might be *Picnocomon* of *Dioſcorides*, as *Geſner* in *hortis* and *Lonicerus* doe. *Fuſchius* calleth it *Barba capri*, and *Lobel Barbi capra*. *Cordus Medeſuſum* from the *Germaine* word *Medeſuſſ*, that is, Meddowſweete. Some as *Lugdunenſis* ſaith, tooke the later to be *Melandrium Plinij*, and ſome alſo call it *Drymopogon*: *Anguillara* calleth them *Potentilla major prima* and *ſecunda*, and *Thalius* the greater ſort *Argentina major*, *Anguillara* ſaith the *Italians* call it *Chriſtoforiana*, the *French* call it *Barbe de Cheuure*, and *Roine des preis*, the *Germanes Geiſbart*, and the greater *Wielde Geiſbart*; and *Camerarius* ſaith *Wormkraut*, becauſe as he ſaith the roote is often found, as if it were eaten by Wormes; but it is more likely for that it helpeth horſes of the Bottes, and Wormes, and ſo he ſaith the countrey people uſed it; the *Dutch Reinette*, and as *Lobel* ſaith *Gheytenbladt*, and *Camecruidt*, in *Engliſh* Medeſweete or Meddowſweete, and Queene of the fields or Meddowes.

The Vertues.

Being neare a little in taſte and ſmell with Burnet, they are moſt likely to bee neare of the ſame faculty, yet *Tragus* accounteth them more hot and dry, they are alſo uſed in the ſame manner and for the ſame purpoſes, to ſtay all manner of fluxes, bleedings, and vomitings, and womens courſes, as alſo their whites: it is ſayd to alter and take away the fits of quartaine Agues, and to make a merry heart, for which purpoſe ſome uſe the flowers, & ſome the leaves: it helpeth alſo ſpeedily thoſe that are troubled with the Collicke, being boyled in wine and with a little

little honey taken warme, it doth open the belly; but boyled in red wine and drunke, it ſtayeth the flux of the belly,&c. it helpeth the Bottes in horſes as you heard before; being outwardly applyed it healeth old Vlcers,that are cancrous or eating,and hollow or fiſtulous,which many have uſed and much commended;as alſo for the ſores in the mouth, and ſecret parts:the leaves when they are full growne being layd upon the skinne,will after a ſmall time, raiſe bliſters thereon as *Tragus* ſaith: the water thereof helpeth the heate and inflammation in the eyes:the ſeede as *Camerarius* ſaith being taken,cauſeth paines in the head; and becauſe both flowers and herbes are of ſo pleaſing a ſweete ſent,many doe much delight therein,to have it layd in their Chambers,Parlars,&c.and Queene *Elizabeth* of famous memory,did more deſire it then any other ſweet herbe to ſtrew her Chambers withall: a leafe or two hereof layd in a cup of wine,will give as quick and as fine a relliſh thereto,as Burnet will,as I ſayd before.

CHAP. LIX.

Potentilla. Wilde Tanſey.

WIlde Tanſey creepeth upon the ground, taking roote at the joynts, every where round about the place where it groweth, that it will quickly take up a great compaſſe, ſhooting forth ſundry winged leaves made of many, ſet on both ſides of a middle ribbe,ſome ſmaller,being ſet among the greater, ſomewhat like unto *Agrimony* or Medeſweete, and like alſo unto Tanſey,from whence it tooke the name; for it partaketh in forme with them all, and dented about the edges, but of a faire greene colour on the upper ſide, and of a ſilver ſhining white colour underneath: it beareth no ſtalk, but the flowers every one of them by it ſelfe ſtand upon a ſmall ſhort footeſtalke, riſing from the joynts with the leaves, which conſiſt of five ſmall yellow round pointed leaves, very like unto thoſe of Cinkefoile, or Five leaved graſſe: the prime roote ſhooteth downeward like the Cinkefoile.

Potentilla. Wilde Tanſey.

The Place.

It groweth almoſt every where wilde abroad in moſt places.

The Time.

It flowreth in *Iune* and *Iuly*.

The Names.

It is called *Potentilla ab eximijs viribus quibus pollet*,and *Argentina a foliorum argenteo ſplendore*, ſome take it to bee *Stephanomelis* of *Pliny*, *lib.*26. *c.*13. others referre it to *Argemone*: It is alſo called *Tanacetum ſylveſtre*, or *agreſte*, as *Brunfelſius* doth. *Tabermontanus* calleth it *Anſerina*, *Geſner in hortis Germaniæ Argemone altera*: and ſo doth *Tragus*, and withall ſaith, it might be called alſo *Millifolium majus*, and ſome *Agrimonia ſylveſtris*: the *Italians* call it *Potentilla*, the *French Argentine ſauuage*, the *Germanes Grenſich* and *Genſerich*, the *Dutch Ganſericke*, wee in *Engliſh* Silverweede,and wilde Tanſey.

The Vertues.

Wilde Tanſey is cold, and dry, and binding withall, ſo that it ſtayeth the laske,and all fluxes of blood in men or women, and ſome ſay it will doe ſo if the greene herbe be but worne in the ſhooes, ſo as it be next the skinne, it ſtayeth alſo ſpittings or vomitings of blood; the powder of the dryed herbe taken in ſome of the diſtilled water, helpeth the whites in women, but more eſpecially if a little Corall and Ivory in powder be put to it: it is alſo much commended to helpe children that are burſten, and have a Rupture: being boyled in water and ſalt; it is alſo ſaid to be good for thoſe that have bin bruiſed by any fall,or the like,to diſſolve the blood,& as it is ſaid doth help to break the ſtone; being boyled in wine and drunke, it eaſeth the griping paines of the bowels, and is good for the Sciatica and joynt aches: the ſame boyled in Vinegar with Hony and Allome & gargled in the mouth eaſeth the paines of the toothach, faſtneth looſe teeth, and the gums that are ſore and ſpongie, and ſetleth the *Uvula* or Pallate of the mouth when it is fallen downe; it clenſeth and healeth thoſe Vlcers that are therein, or in the ſecret parts, and is ſingular good alſo for inward wounds, and to conſolidate or cloſe the lips of greene wounds, as alſo to heale the old moyſt and corrupt running ſores, in the legges or elſewhere: being bruiſed and applyed to the ſoles of the feete, and to the wreſts of the hands,it wonderfully cooleth the hot fits of Agues,be they never ſo violent:the diſtilled water clenſeth the skinne of all diſcolourings therein,as morphew,ſunburning,&c. as alſo pimples, freckles and the like, and dropped into the eyes, or wet cloathes applyed unto them, taketh away the heat and inflammations in them.

CHAP. LX.

Agrimonia ſive Eupatorium. Agrimonie.

WEe have divers ſorts of Agrimonie, ſome of our owne land, and ſome of others, as you ſhall have them here ſet forth unto you.

1. *Eupatorium ſive Agrimonia vulgaris.* Our common Agrimonie.

Our common Agrimonie hath divers long leaves made of many ſet upon a ſtalke, ſome greater, others ſmaller, all of them dented about the edges, greene above, and grayiſh underneath, and a little hairy withall; among which ariſeth up uſually but one ſtiffe, ſtrong, rough or hairy browne round ſtalke, 2. or 3. foot high, with ſmaller leaves ſet here and there thereon: at the top whereof grow many ſmall yellow flowers, one above another in long ſpikes; after which come rough heads of ſeeds hanging downewards, which will cleave to any thing that ſhall rubbe againſt them, and ſticke upon garments, being touched or caſt thereon: the roote is blacke, long and ſomewhat wooddy, abiding many yeares, and ſhooting afreſh every ſpring; it hath a reaſonable good ſent yet very ſmall.

2. *Agrimonia odorata.* Sweete ſmelling Agrimonie.

This other or ſweete ſmelling Agrimonie, is ſo like the other that there is hardly any difference to be diſcerned by the eye, but by the noſe onely, except that if there be any difference, this groweth ſomewhat leſſer, with rounder and whiter leaves then the other, and the roote of a darke red colour, but the ſmell herein doth much ſurpaſſe the other, and ſo doth the taſte being aromaticall and aſtringent; whereby it is held to bee of more excellent uſe to corroborate and ſtrengthen weake parts.

3. *Agrimonoides.* Baſtard Agrimonie.

This herbe that is like to Agrimonie, and yet is none, and therefore called Baſtard Agrimonie, hath divers long, ſoft and hairy leaves next the ground, every one upon a long reddiſh hairy footeſtalke, which are cut and divided into many parts or leaves, ſeaven for the moſt part, three on each ſide and the ſeventh at the end, but having ſome ſmaller ones betweene them, like as Agrimony hath, yet ſomewhat rounder then they, and all of them ſmaller dented, and ſharper pointed, of a darker greene colour on the upper ſide, and grayiſh underneath: among theſe leaves riſe up ſundry weake ſtalks, not fully ſtanding upright, but leaning downewards, whereon are ſet very ſparſedly ſuch like leaves, but ſmaller and rounder, with ſmall peeces at the joynts of every of them; & at the tops come forth three or foure hairy greene huskes like cups dented at the brims, out of every one whereof riſeth a ſmall yellow flower, like unto Agrimony, yet ſometimes they ſcarſe appeare above the huskes to bee ſeene; wherein after they are fallen and paſt, appeare ſmall long and round graynes like unto the graines of

1. *Agrimonia vulgaris.* Common Agrimony.

3. *Agrimonoides.* Baſtard Agrimony.

wheate, two ſtanding together like two ſmall lumpes, which fall out of the huskes of themſelves, when they are ripe, leaving the huske emptie and gaping; the roote is ſmall reddiſh and wooddy, abiding and not periſhing in the winter.

4. *Eupatorium Cannabinum.* Hempelike Agrimony.

The Hempelike Agrimony hath many long darke, greene, ſoft or woolly leaves, lying upon the ground, among which riſeth up a ſoft whitiſh ſtalke, full of a white pith within it, to the height of two or three cubits ſometimes, ſet full of ſuch like leaves as grow below up to the top, where the flowers breake forth, many ſtanding together in tufts, being very ſmall and moſſie, of a pale purpliſh colour, which turne into downe, and is carried away by the winde: the roote ſpreadeth farre, with many ſtrings and fibres thereat: the whole plant hath a little ſweete ſent in it, but is very bitter, and ſo is the roote alſo.

5. *Eupatorium Cannabinum Americanum latifolium.*

The broader leafed Hempelike Agrimony of *America.*

This broader leafed kind of Agrimony groweth greater and higher then the former with a browniſh ſtalke, and longer and larger leaves thereon, ſo that ſome have compared them to thoſe of Elecampane: the flowers grow at the top of the ſtalke in greater number, and more ſparſedly with longer ſcaly husks being many long threds ſtanding in the middle, of a more purpliſh blew colour, and the ſeede at their bottomes, which together are blowne away with the winde.

6. *Eupatorium Cannabinum Americanum anguſtifolium.*

Narrow leafed Hempelike Agrimony of *New England*

The other kind of *American* Agrimony groweth at the firſt with a few ſmall hairy leaves upon the ground, unevenly dented in ſome places on the edges, and in others but little or not at all dented: the ſingle hairy thicke round brittle ſtalke of two or three foote high or more, is full ſet on all ſides, very thicke with longer and narrow leaves without

4. *Eupatorium Cannabinum.* Hempelike Agrimony.

5. *Eupatorium Cannabinum Americanum latifolium.*
The broader leafed Hempelike Agrimony of *America.*

7. *Eupatorium aquaticum duorum generum.*
Water Agrimony of two ſorts.

order,

order, ſome dented and ſome not, of 2. 3. and 4. inches long a peece, and halfe an inch broad or leſſe, of a pale greene colour and ſoft, full of branches from the middle at the leaſt upwards and ſmaller leaves on them, with very many ſmall moſſie pale threds for flowers on every branch, out of ſmall greene huskes or heads, which with the ſeede almoſt inſenſible, is carried away with the wind, that one would thinke it had no ſeede at all, which yet will ſpring very plentifully before winter of it owne ſowing: the roote is a few hard ſprayes with ſmall fibres at them, and periſhing yeerely after it hath ſeeded.

7. *Eupatorium aquaticum duorum generum.* Water *Agrimony* of two ſorts.

Although all theſe ſorts of Hempe-like *Agrimony* doe uſually grow by watery ditch ſides, and the like moriſh places, yet becauſe they will alſo grow well in different ſoiles, I thinke it not a miſſe to joyne them all together, for the likeneſſe of name, forme, and qualities. Of this water *Agrimony* we have two ſorts of our owne Land, and another alſo out of *America* or New *England*, being in all other things very like one unto another, but onely in the placing or ſetting of the leaves upon the ſtalkes; which in one ſort hath divers leaves ſet together, like the fingers of an hand, all meeting together at the bottome, ſet by diſtances at the ſtalkes, every one not divided, but whole, yet dented about the edges, and in forme and greeneneſſe like unto the leaves of wilde Hempe, or of the former *Agrimonies* but ſofter: and in the other, every leafe is ſomewhat divided, three or five upon a ſtalke, two at a joynt: the flowers are yellowiſh browne, made of many leaves like a ſtarre, ſet about a middle thrum, with greene heades under them, divers ſtanding together, thruſting forth from the joynts with the leaves, and at the toppes of the branches, which turne into long flat rugged ſeede, which will ſticke to any garment it toucheth: the roote is made of many blacke ſtrings and fibres, encreaſing much, the whole plant is ſomewhat aromaticall ſmelling ſweete, and taſting ſomewhat ſharpe like Pepper, and ſo doth the roote alſo.

Americanum. We have another of this laſt ſort, brought us from *Virginia* and New *England*, whoſe great hard ſolide, browne round ſtalke, of 3. 4. and five foote high, is wonderfull full of long branches from the bottome, ſet with joynts ſpotted red, on the younger greene ones, with large greene leaves on them, the loweſt having five on a ſtalke, thoſe upward but three yet larger than the former, as the flowers and ſeede is alſo, yet not rough but ſmoth flat and blackiſh: this hath no ſharpeneſſe of taſte in it.

The Place.

The firſt groweth in the borders of fieldes, by ditches and hedge ſides throughout all the Land: the ſecond is a ſtranger to us, growing with us onely in the gardens of the curious, but is naturall to *Italy* in many places, both the former and this growing neere one to another, or not farre diſtant: the third *Columna* found in *Naples*, and was ſent to *Bauhinus* from many other parts of *Italy* likewiſe, as he ſaith himſelfe: the fourth is found in many places that are wet, as the brinckes of ditches, and water courſes, and in the upland grounds alſo, where it will thrive and endure as well: the fift, ſixth, and laſt came to us from New *England* & *Virginea*, the two firſt of the 7. grow ſometimes in the very water; the laſt in ſhallow ponds and plaſhes of water, as alſo ſometimes in places diſtant from them: the laſt *American* groweth huge and great in our garden grounds, comming firſt unto us out of New *England*, among the earth that *Iohn Newton* a Chirurgion of *Colliton* in *Somerſetſhire* brought me with *Planta Cardinalis*, their little red Lillies and other plants.

The Time.

They doe all flower in *Iuly* and *Auguſt*, and the ſeede is ſoone ripe after, yet the laſt *American* flowreth lateſt.

The Names.

The firſt is called in Greeke εὐπατώριον *Eupatorium*, and ſo the Latines call it alſo, of *Eupator* the firſt finder of it, as *Pliny* ſaith, who calleth it *Eupatoria*; and as it is thought is his *Argemonia in arvis naſcens*, but *Dioſcorides* ſheweth that this was an errour in his time, in miſtaking *Argemonia*, for *Agrimonia*. Some alſo call it *Hepatorium quoniam hepati præcipue medetur*: becauſe it is a chiefe helpe to the Liver: it is alſo called *Agrimonia* of divers: ſome other names are alſo given unto it, as *Marmorella*, *Concordia*, *Lappa inverſa*, and *Ferraria*. The *Arabians* call it *Cafal*, *Cafel*, and *Gafel*: the *Italians Agrimonia*, and ſo doe the *Spaniards*, the *French Agrimonie*, and *Eupatoire*. The *Germanes Odermeing*, and *Bruchwurtz*: the *Dutch Agrimony*: and we in *Engliſh Agrimony* or common *Agrimony*. All the Apothecaries of our Land, eſpecially of *London* now adayes, doe uſe this firſt kinde of *Agrimony*, as the moſt aſſured *Eupatorium* of *Dioſcorides*: howſoever in former times, both we and they beyond the ſeas, did uſually take the *Eupatorium Cannabinum*, which they called *Eupatorium vulgare*, for the true kinde, and either of ignorance not knowing the right, or of wilfulneſſes in not enduring to be with drawne from their old errours, but our age hath reformed very many of theſe errours, we were formerly nuſled up in; and no doubt but by the diligent ſearch of divers for the truth; both the light that hath riſen hath appeared, and the darkneſſe that remaines may be expelled, which time muſt as it hath done in part already, bring to paſſe, the pertinatious wilfulneſſe of many being the cauſe that it is not wholly performed as yet. *Anguillara* firſt, and *Columna* after him doe make this *Eupatorium* of *Dioſcorides*, to be that of *Avicen* alſo, and ſo to be both one. *Dodonæus* becauſe he would not acknowledge the *Ageratum* of *Dioſcorides*, to be the *Eupatorium* of *Meſues*, runneth himſelfe a ground, on the dangerous ſhelfe of two errours, namely that the *Eupatorium* of *Meſues* and *Avicen*, doe not differ, and the *Eupatorium* of *Meſues* and *Dioſcorides*, be both one; when as it is in neither of them true; for as we ſhewed in the Chapter of *Ageratum*, that *Ageratum* was the true *Eupatorium* of *Meſues*, which differeth much from this of *Dioſcorides*; ſo doth that of *Meſues*, from that of *Avicen* alſo, which is by the moſt judicious now adayes, accounted to be the firſt *Eupatorium Cannabinum*, here ſet downe and as before is ſayd was in former times called *Eupatorium vulgare*: yet there is ſome doubt therein, in that *Avicen* ſaith, the flowers of his *Eupatorium* are like thoſe of *Nenufar* or water Lilly; which the moſt judicious know not well how to reconcile, but doe verily ſuppoſe ſome errour or miſtake to be in the text: and although it be not the true *Eupatorium* of *Dioſcorides*, the errour thereof being now reformed, both their deſcriptions and figures inducing the ſame unto you, yet is it not without very ſpeciall properties, as you ſhall heare by and by: the ſecond is called *Agrimonia odorata* by *Camerarius*, and *Eupatorium alterum odoratum, & aromaticum* by *Columna*: the third is called *Agrimonoides* of *Columna*, of *Bauhinus Agrimoniæ ſimilis*, and of ſome *Pimpinella folio Agrimoniæ*: the fourth was uſually called in former times beyond the Seas, as I ſayd *Eupatorium vulgare*, as *Matthiolus* and others doe ſet it downe. *Fuſchius* called it *Eupatorium adulterinum*, and *Dodonæus* and *Thalius Pſeudo hepatorium mas*: *Lobel*

calleth

calleth it *Cannabina aquatica, ſive Eupatorium mas. Geſner Eupatorium aquaticum, & Trifolium cervinum aquaticum. Baptiſta Sardus* calleth it *Terzola, Anguillara, Geſner in hortis Germaniæ, Lacuna, Lonicerus,* and *Camerarius* call it *Eupatorium Avicennæ.* This is called in high *Dutch* S. *Kunigunds Kraut,* that is *Herba Sanctæ kunigdis & Wafferdoſt,* of the low *Dutch Boelkencruiit:* the firſt is called by *Cornutus Eupatorium foliis Enulæ,* and I according to the title, to put a difference betweene it, have ſet *latifolium,* and the other of that ſort which I call *anguſtifolium,* and hath onely ſprung with me, and hath not beene mentioned by any before: the laſt which as I ſayd is of two ſorts, the one with divided leaves, the other with whole, are diverſly named by divers; for that with divided leaves is called by *Tragus Verbena ſupina,* by *Cordus* upon *Dioſcorides Verbenaca recta,* by *Geſner in hortis, Forbeſina Bononienſium,* and by ſome as he there ſaith, *Conyza paluſtris, & Verbeſina* in his Appendix; by *Dodonæus Hepatorium aquatile, Ruellius* tooke it to be *Hydropiper,* and ſo did *Lugdunenſis,* but yet doth confute his opinion, and ſheweth the differences, as *Matthiolus* before hath done; by *Cæſalpinus Bidens folio tripartito diviſa,* and by *Bauhinus Cannabina aquatica folio tripartito diviſo*: the other with whole leaves is called by *Lobel, Eupatorium Cannabinum fœmina Septentrionalium;* by *Tabermontanus, Eupatorium Cannabinum Chryſanthemum;* by *Lugdunenſis Hydropiper aliud Dalechampii;* by *Cæſalpinus, Bidens folio non diſſecto,* and by *Bauhinus* in his *Prodomus, Cannabinæ aquaticæ ſimilis capitulis nutantibus,* and in his *Pinax Cannabina aquatica folio non diviſo*: that of *Virginia* may well goe under the ſame title.

The Vertues.

The ſweete *Agrimony* is held by divers to be the more excellent in all the properties of *Agrimony;* but becauſe we cannot have it in that quantity, that may ſerve all mens continuall uſes, our ordinary ſort will ſerve ſufficiently well and effectually. *Serapio* ſaith, it is hot and dry in the firſt degree, and as *Galen* ſaith, it is of thinne parts, and hath a clenſing and cutting faculty, without any manifeſt heate; it is alſo moderately drying and binding; it openeth the obſtructions of the Liver, and clenſeth it; it helpeth the jaundiſe, and ſtrengthneth the inward parts, and is very beneficiall to the bowels, and healeth their inward woundings and bruiſes or hurts, and qualifieth all inward diſtemperatures, that grow therein: the decoction of the herbe, made with wine and drunke, is good againſt the ſting, and bitings of Serpents, and helpeth them that have foule, or troubled and bloody waters; it is good for the ſtrangury, and helpeth them to make water currantly, and helpeth alſo the collicke; it clenſeth the breſt, and helpeth the cough: it is accounted alſo a good helpe to ridde a *quartaine* as well as a *tertian* ague, by taking a draught of the decoction warme before the fit, which by altering them, will in time ridde them: the leaves and ſeede ſaith *Dioſcorides,* the ſeede ſaith *Pliny,* ſtayeth the bloody flixe, being taken in wine: outwardly applyed it helpeth old ſores, cancers, and ulcers that are of hard curation, being ſtamped with old Swines greaſe and applyed, for it clenſeth and afterwards healeth them: in the ſame manner alſo applyed, it doth draw forth the thornes or ſplinters of wood, nayles, or any other ſuch thing, that is gotten into the fleſh, and helpeth to ſtrengthen members that be out of joynt: it helpeth alſo foule impoſtumed eares, being bruiſed and applyed, or the juyce dropped into them: the diſtilled water of the herbe, is good to all the purpoſes aforeſaide; either inward or outward. The Hempe like *Agrimony,* or *Eupatorium Cannabinum,* is of the ſame temperature of heate and dryeth, for it alſo openeth, clenſeth, cutteth and maketh thinne thoſe humors that are thicke and tough, and therefore is very effectuall for the dropſie, yellow Iaundiſe, obſtructions of the Liver, and hardneſſe of the Spleene, fulneſſe of humors, and the evill diſpoſition or habit of the body: the juyce hereof drunke, is commended much againſt the impoſtumes that come of a cold cauſe within the body, and for thoſe that are without, the herbe bruiſed and applyed outwardly: the decoction thereof taken before the fits of long and lingring agues, doth helpe much to free any from them: the ſame alſo provoketh urine, and womens naturall courſes; and boyled with Fumiterry in whey and drunke, helpeth ſcabbes, and the itch, which proceede of ſalt and ſharpe humours; but the juyce mixed with vinegar, and annointed cureth it outwardly; and cureth the Leproſie alſo, if it be taken in the beginning, but the juyce being drunke, is held to be more effectuall: the juyce being clarified and dryed, and the weight of a ſcruple taken in pills, killeth the wormes of the belly, and the leaves ſteeped in drinke, and given to children doth the ſame. The leaves are often given by the Country people, to their cattle, and other beaſts, troubled with coughes, and when they are broken winded, or have griping paines within them, all which it helpeth: the flowers chiefely are uſed to heale both greene and old ſores, but the herbe it ſelfe will doe ſo likewiſe; it is ſayd that hunters have obſerved, that Deare being wounded, by the eating of this herbe have beene healed of their hurts: the dryed herbe being burned, driveth away by the ſmoake and ſmell thereof, all flies, waſpes, and the like, and all other hurtfull and venemous creatures.

CHAP. LXI.

Cannabis. Hempe.

THere are two kindes of Hempe, the tame or manured, and the wilde or baſtard; of the manured kind there are two ſorts, male, and female, of which I intend to entreate in this Chapter; and of the wilde or baſtard ſorts in the next.

Cannabis ſativa. Manured Hempe.

The Manured Hempe, (which is of ſo great uſe, both for linnen cloath and cordage) is as I ſayd of two ſorts, male and female as they are called, yet both riſe from one and the ſame ſeede; and herein is ſomewhat like the *French* Mercury, but how this change in nature ſhould be, no man can give a reaſon: the male hath the ſtronger ſtalke, and more buſhie, and the leaves greater, and of a darker greene colour, and bearing ſeede without any ſhew of flowers, and endureth longer, before it be ripe to cut downe: contrariwiſe, the female hath a ſingle ſtalke, for the moſt part, with few or no branches, and beareth flowers, but no ſeede followeth, and is ripe, and muſt be cut downe, or pulled up before the other: they both riſe up to a great height, even ſixe or ſeven foote high or more, with many leaves ſet thereon at diſtances, every one divided into 5. or 6. or 7. ſeverall leaves, joyned together at the bottome of them, and dented about the edges, ſomewhat like unto the forme of the leaves of the

the *Palma Chriſti*, *Lupine* and baſtard Hellebor, every one ſet upon a long foote ſtalke, of a darke greene colour, and of a ſtrong unpleaſing ſavour; the flowers are ſmall, and of a whitiſh yellow colour, ſtanding many together, upon a long branch, which turne into duſt, and are carried away with the wind, not carrying any ſeede after them; which being the tenderer and weaker, and the ſtalke hollow and not ſo ſtrong, maketh the finer ſtuffe, to be ſpunne and woven into linnen cloath, fit for mens bodies, or other the like uſes, and is called of ſome Sommer Hempe: but the other being ſtronger and called winter Hempe, becauſe it is not gathered untill toward Winter, or at the leaſt, not of a moneth after the other, beareth ſeede in the ſame manner, that the other bore flowers on long branches, which is round and conteined in round heads: the rootes are made of many ſtrong ſtringes which take faſt hold in the ground, but dye and periſh every yeare: to ſhew you the manner of ſteeping, drying, beating, and clenſing hereof, to be made into cloth or Cordage, is not my purpoſe, nor pertinent for this worke; beſides that, it would take up too much roome and time; it is familiarly known to every country huſwife almoſt.

Cannabis ſativa.
Manured Hempe.

Virginenſis major. We have had from *Virginia* a very great kinde of Hempe, with greater ſtalkes, and much larger leaves and flowers, which being broken down with the wind, when it was almoſt at the perfection, we cannot fully expreſſe it as we would, and as time may doe it hereafter.

The Place.

Although *Pliny*, *lib.* 20. *c.* 23. ſaith that Hempe was formerly found wilde, yet know we not in theſe dayes, where ſuch may be found; for in all places of the world I thinke, it is onely ſowne in fieldes and places, choſen out for the purpoſe.

The Time.

It is ſowne in the end of *March*, or beginning of *Aprill*, and is ripe in *Auguſt* or *September*, as the two ſorts grow ripe and fit to be gathered.

The Names.

It is called in Greeke κάνναβις, and ſo *Cannabis* in Latine alſo, from the Greeke word κανναβοί, ſaith *Lobel*, *quod fonticulos ſparſasve ſcaturigines ſignificat, quo loci lubens ſponte, & ſata luxuriet*: the *Arabians* call it *Cannab.* and *Schehedenegi*: the *Italians Canape*: the *Spaniards Cannamo*: the *French Chanure*, and *Chaneve*: the *Germanes Zamer Hauff*: the *Dutch Kempe*, and we in *Engliſh* Hempe.

The Vertues.

Hempe is cold and dry ſay *Tragus* and *Lonicerus*, but *Galen* in *lib.* 7. *ſimpl. medicament. & primo de aliment facultatibus*, ſaith it is hot and dry, and ſo doe *Matthiolus*, *Ruellius*, *Fuſchius*, and *Lugdunenſis*, agreeing with him therein: the ſeede of Hempe conſumeth wind, and by the much uſe thereof, doth diſperſe it ſo much, that it dryeth up the naturall ſeede of procreation, therewith: for it is hard of digeſtion, hurtful to the head & ſtomack, and breedeth ill blood and juyce in the body, yet being boyled in milke and taken, helpeth ſuch as have a dry and hot cough, as *Tragus* ſaith: the *Dutch* as one ſaith doe make an Emulſion out of the ſeede, and give it with good ſucceſſe to thoſe that have the Iaundiſe, eſpecially in the beginning of the diſeaſe, if there be no ague accompanying it, for it openeth the obſtructions of the gall, and cauſeth digeſtion of choller therein: but as *Matthiolus* ſaith, the women in *Germany* went a wrong courſe, to give their children the decoction of Hempe ſeede for the falling ſickneſſe, which it did rather augment, then helpe to take away: the Emulſion or decoction of the ſeede, ſtayeth laskes and fluxes that are continuall, eaſeth the paines of the collicke; and allayeth the troubleſome humours in the bowels: divers alſo doe ſtay bleedings herewith, whether at the mouth or noſe, or at other places, by frying the leaves with ſome of the blood that hathcome from them that bleed, and ſo given them to eate; it is heldvery good to kill the wormes in man or beaſt, as alſo the wormes in the eares, or the juice dropped therein, or to draw forth any other living creature that hath crept therein; and to ſhew the ſtrength hereof for this purpoſe, *Matthiolus* ſaith, that the decoction thereof, powred into the holes of earthwormes, will draw them forth, and that fiſhermen and anglers have uſed this feate to get wormes to baite their hookes. The decoction of the roote is ſayd to allay inflammations in the head, or any other part, the herbe it ſelfe, or the diſtilled water thereof applyed performeth the like effect; the ſame decoction of the rootes, eaſeth the paines of the gout, the hard tumours, or knots of the joynts, the paines and ſhrinking of the ſinewes, and other the like paines of the hippes: it is good to be uſed, for any place that hath beene burnt by fire, if the freſh juyce be mixed with a little oyle or butter. *Matthiolus* ſaith, that Hempe ſeede, given to Hennes in the winter, when they lay feweſt egges, will make them laye more plentifuliy.

CHAP. LXII.

Cannabis ſylveſtris ſive ſpuria. Wilde or baſtard Hempe.

THere are two or three ſorts of herbes, that are accounted by divers for wilde or baſtard Hempes, yet are none of them the true *Cannabis ſylveſtris* of *Dioſcorides*: *Bauhinus* therefore in not ſo accounting of them, referreth them to the kinds of Nettles, as you ſhall heare by and by.

1. *Cannabis ſpuria prima.* The firſt baſtard Hempe.

This baſtard Hempe riſeth up with a reaſonable great hairy ſquare ſtalke, not very ſtrong nor upright, but as it were leaning downe, with divers joynts bunching out like knees, and two leaves ſet at every of them, ſomewhat long hairy and pointed, of a freſher greene colour then the manured Hempe, and dented about the edges: at the joynts likewiſe come forth divers branches joynted and ſet with leaves in the ſame manner, where about towards the toppes grow divers hoodded and gaping flowers, like thoſe of the dead Nettle, but larger, and greater, of a pale purpliſh colour, ſtanding in ſmall greene prickly huskes; wherein afterwards groweth the ſeede, being ſmall and round, three or foure growing together: the roote is hard and white, and ſomewhat ſpreading, but dying before winter.

There is another hereof, whoſe flower is of a perfect white colour for the moſt part, or a little pale whayiſh, *Flore albo* which doth plainely expreſſe the difference.

2. *Cannabis ſpuria altera.* The ſecond baſtard Hempe.

This other baſtard Hempe differeth not in ſtalke from the former, but the leaves are ſhorter and rounder; the flowers hereof are not ſo great as they, the uppermoſt part or hood whereof, is of a pale colour tending to yellow, and the lower part of a deeper red or purple colour: the huskes of the flowers are ſomewhat more prickly then the other.

3. *Cannabis ſpuria tertia.* The third baſtard Hempe.

The third baſtard hempe is in the growing much like the former, but that the leaves at the joynts are ſomewhat long and narrow, a little ſadder and not dented about the edges in the moſt; the flowers hereof are hooded and gaping, but they are of a pale yellowiſh colour wholly, with a little or no ſhadow or ſpot therein, and ſtand thicker about the joynts, whoſe huskes have longer and ſharper points then the reſt.

The Place.

All theſe doe grow as well in moyſt grounds as in dry, by ditch ſides, and by the path wayes, under walls, &c. and ſome of them will be found in gardens, to be continually pulled up as a weede, and unprofitable herbe: yet the ſecond ſort with a white flower was found by the path wayes neare *Clapham*, and in the ditches by *Redriffe*, or *Rother Hithe*.

1. *Cannabis ſpuria prima.*
The firſt baſtard Hempe.

3. *Cannabis ſpuria tertia.*
The third baſtard Hempe.

The Time.

They flower for the moſt part in *Iuly*.

The Names.

Moſt writers call theſe *Cannabes ſpuriæ*, and *ſylveſtres*; yet as I ſayd before, *Bauhinus* doth call them, *Vrticæ fœtæ aculeatæ*. The firſt is called, *Cannabis ſylveſtris*, by *Tragus* and *Lugdunenſis*, and *Spuria altera* by *Lobel*, by *Tabermontanus Cannabina alba*, and by *Bauhinus Vrtica aculeata folijs ſerratis*, the ſecond is the *Cannabis ſylveſtris ſpuria tertia* of *Lobel*, *Alyſſum arvenſe album* of *Tabermontanus*, *Vrtica aculeata folijs ſerratis altera* of *Bauhinus*, who thinketh it may be alſo the *Sideritis Cordi*, whereof *Thalius* maketh mention in *Hercynia ſylva*. The third is called by *Lobel*, *Cannabis ſpuria facie Vrticæ*, by *Bauhinus Vrtica aculeata folijs non ſerratis*, and is the *Sideritis altera Matthioli*, as *Lugdunenſis* expreſſeth it.

The Vertues.

There is little uſe made of theſe herbes, eyther inwardly or outwardly, yet they are thought to bee neare the temperature and qualities of the former Hempe: *Lobel* ſaith they are uſed as an aſſured remedy againſt nodes and wennes, and other hard tumours in the fleſh, when other things have failed and would do no good.

CHAP. LXIII.

Iſatis ſive Glaſtum. Woade.

OF this herbe there is accounted two ſorts, the one manured, the other growing wilde; yet they are both ſo like the one unto the other, that as it is thought the manuring onely cauſeth the difference; a third ſort I have added to them for the colours ſake though much diſproportioned in forme.

1. *Glaſtum ſativum.* Manured Woade.

Woade that is ſowen in fields for uſe, hath divers large, long and ſomewhat broad leaves, like unto thoſe of Ribwort Plantaine, but larger thicker, and of a darker blewiſh greene colour; from among which ariſeth up a ſtrong ſtalke three or foure foote high, and ſometimes more, with divers ſuch leaves ſet thereon, but ſmaller up to the top, where it ſpreadeth into divers branches, at the ends whereof grow ſmall yellow flowers, in whoſe places come long flattiſh huskes, or cods like tongues, blacke when they are ripe, and pendulous or hanging downewards, wherein lye the ſeede, which if it be a little chawed or broken with moyſture, will give a blew colour: the roote is white and long, growing downewards.

2. *Glaſtum ſylveſtre.* Wilde Woade.

This wilde Woade differeth little from the tame or manured, but that it is ſmaller, the ſtalke ſlenderer, the leaves leſſer, and the huske or cods ſmaller and narrower.

3. *Nil ſive Anil, Glaſtum Indicum.* *Indico* or *Indian* Woade.

Although *Nil* or *Indico* be not in forme like Woade, yet for the rich blew colour ſake I thinke good to make

3. *Glaſtum ſativum.* Manured Woade.

3. *Nil ſive Anil, Glaſtum Indicum.* *Indico* or *Indian* Woade.

mention

mention of it here with it, not onely to ſhew you what it is, and how made, but to incite ſome of our nation, to to be as induſtrious therein as they have beene with the former Woade, ſeeing no doubt but it would bee more profitable. *Camerarius* and *Cluſius* have both had the ſeede of a plant ſent them under the name of *Nil*, or *Anil*, as they ſay, but having growne with them they have judged it rather to be another plant, then that whereof it bore the name; for *Cluſius* ſaith, that his plant was like unto a ſmall *Colutea*, which he afterwards as hee ſaith found to be *Alpinus* his *Egyptian Seſban* (and ſure he gheſſed ſomewhat neare it, for if it be not the ſame it is very like it, as you ſhall heare by and by) and *Camerarius* ſaith his plant had leaves like unto *Barba Iobis frutex*, but larger; which compariſon may hold a fit correſpondence likewiſe; yet *Linſcot* ſaith the true hath leaves like Roſemarie. But I ſhall here give you the deſcription of the plant by two ſeverall men; the one is *Francis Ximenes*, as he is ſet downe in *Ioannes de Laet* his deſcription of *America*, or the *Weſt Indies*, in pag. 330. and 331. who ſaith it is a ſhrubbe, producing many round ſmooth wooddy ſtemmes from the roote, about ſix palmes or ſpans high, about the bigneſſe of ones little finger, of an aſh colour, with leaves thereon like unto Cicers, having ſmall whitiſh red flowers, and afterwards many long Cods growing together, and hanging downewards like unto the wormes called *Aſcarides* which we call Arſewormes, yet ſomewhat thicke and full of blacke ſeede (*de Laet* addeth in a Parentheſis, Some ſay the ſeede is like unto *Fenugreck*, flat at both ends as if it had beene cut of.) For the manner of making whereof hee ſaith, They caſt the leaves into a braſſe veſſell, pouring thereon ſcalding hot water, or rather lukewarme (yet ſome allow of cold water as beſt) ſtirring them very well that the water may draw out the tincture, which they poure out into another veſſell that hath an hole therein ſomewhat high, whereout the cleare water may paſſe, the thicke coloured ſubſtance remaining behinde, which afterwards they ſtraine through a cloth or bag, ſetting the thicke ſubſtance in the Sunne, and make it into cakes which is then dryed and hardened in pans at the fire; Thus farre *de Laet*. The other deſcription is by Mr. *William Finch* a *London* Merchant, as it is ſet downe by Mr. *Purchas*, in his fourth Booke of Pilgrims, the 4 Chap. pag. 429. It is a ſhrub ſaith he, not above a yard high, and as bigge as a mans thumbe at the biggeſt; the branches are wooddy like unto Broome, having many leaves ſet together on a ſhort footeſtalke, in forme like Cives (miſprinted for Cicers) or Ciche peaſe, or like thoſe of *Sena*, but ſhorter and broader: the flower (ſaith he) is like unto an Hearts eaſe; the ſeede is incloſed in a ſmall round cod about an inch long reſembling *Fenegreck* ſeede, but more blunt at both ends (ſuch very ſeedes for colour alſo we have often had ſent for *Indico* ſeede, yet never any ſprang with us but once, and that but one plant, and over haſtily plucked up before it had any forme to be diſcerned, yet the ſmall threddy roote was of a pale blew colour, which I doe keepe by me to ſhew: the ſeede alſo while it is freſh being ſteeped in water gave a blewiſh colour.) Theſe deſcriptions ſo like in moſt things and ſo nearely alſo reſembling *Alpinus* his *Seſban*, but that it hath a yellow flower, perſwadeth me that *Seſban* being undoubtedly a kind of *Glaux Leguminoſa*, & ſo may *Indico* be alſo but differing in the Dye. The manner of making as Mr *Finch* ſaith is thus (being variouſly deſcribed by others) They gather the leaves (when they have cut the branches, in *Auguſt* and *September* after the raines, the ſeede being ripe in *November*) and caſt them into a long Ceſterne powring water thereon, and preſſe them downe with ſtones that they may be overcovered, ſo abiding for certaine dayes, that the ſubſtance of the herbe may be drawne out into the water, which they let forth into another round Ceſterne, in the minſt whereof is another ſmall Ceſterne, or Center (the meaning whereof I doe not underſtand) and labour it with great ſtaves, like batter or white Starch, ſcumming of the cleare water after it is ſetled; then labour it afreſh, and draw off the cleare water againe being ſetled, doing thus ſo often untill nothing but a thicke ſubſtance remaine, which they dry in the Sunne being ſpread upon cloth, and after it is a little hardned, they make it into ſmall balls with their hands, laying them to dry on the ſand, for any other thing would drinke up the colour, as alſo if it take raine in the drying it will loſe his colour and gloſſe. After it is ſowen it endureth three yeares: that *Indico* of the firſt yeare while the plant is tender, is weighty and reddiſh called *Notee*: that of the ſecond yeare is rich, being very light and of a perfect violet colour ſwimming on the water, and is called *Cyeree*: that of the third yeare when the plant is declining (and peradventure but fabulous traditions) is a weighty blackiſh *Nil* the worſt of the three, and called *Catteld*. The beſt is made ſaith hee, about *Biany* neere 20. miles beyond *Fetipore* in the *Mogols* country in the *Eaſt Indies*. And *Ximenes* aforeſaid as *de Laet* hath it, ſaith, the *Indians* of the Weſt call the Plant *Xihuiquilitl pitzahuac* and the *Mexicans* call the tincture made thereof *Mohuitli* and *Tlecohuitli*, but the other *Barbarians Tlacchoylinuhuitl*, and therewith colour their haire blacke. I have not heard that good *Indico* is one of the Merchandiſes of the Weſt, but of the Eaſt *Indies* onely. *De Laet* having given the figure of a branch of *Indico*, I doe here likewiſe exhibite the ſame.

The Place.

The wilde kinde groweth in ſundry untilled places and fields in *Germany*, as it is ſayd, but the manured is ſowen as well in *Germany*, *France*, and *Spaine* as in *Italy* alſo, in *Umbria* neare unto *Nocera*, as *Matthiolus* ſaith, where there is a towne called *Guado*, of the Woade that grew there abundantly; and in the *Ilands* of *Terceras* belonging to *Spaine*: Some have ſowen it in our owne land, but they have found it to be the cauſe of the deſtruction of their Bees; for it hath beene obſerved, that they have dyed as it were of a Flix that have taſted thereof: it is ſayd that in ſome places they ſow their Woade upon the ſame ground, that afterwards they ſowed their Corne, which crop of Woade is three times cut in a yeare, and that theſe rootes that are not turned up with the Plough will beare ſeede among the Corne. The Plant whereof the *Nil* or *Indico* is made, groweth in divers places of the *Eaſt Indies*, but eſpecially in *Guzurate*, and the beſt in and about *Bianie* in the *Mogols* countrey.

The Time.

Woade flowreth in *Iune*, but the ſeede is late ripe.

The Names.

It is called in Greeke Ἰσάτις, and *Iſatis* in Latine, *Glaſtum* alſo and *Guadum* of ſome, after the *Italian* word *Guado*, whereby they call Woade. *Cæſar* in his firſt booke, *de Bello Gallico*, maketh mention of *Glaſtum*, wherewith the ancient Brittaines did colour themſelves to ſeeme the more terrible to their enemies in battaile as it is thought; or that they did then as the Savages of the Weſt *Indies* doe now delight in ſuch a colour, to paint their naked skinnes therewith. Pliny alſo ſpeaketh of the Brittaines uſing of *Glaſtum* in his 22. Booke and firſt Chap. but divers doe diverſly imagine from whence the word *Glaſtum* ſhould be derived; ſome have imagined, that

in both thoſe Authors the word *Vitrum* ſhould be read in ſtead of *Glaſtum*; becauſe the *Germane* word *Glaſſe*, from whence they thinke *Glaſtum* is derived, is ſignified by *Vitrum*; and ſome alſo would turne *Vitrum* into *Nitrum*; but *Nitrum* is not for ſuch uſe, for it is yet very rare or ſcarſe ſeene of any with us: the *Arabians* call it *Dili*, *Deligi*, *Chate*, *chatis*, *Alchat*, *Alden*, or *Adhlen*, or as *Avicen* in his 512. Chap. ſaith *Nil*; yet in his 306. Chap. he hath another *Nil*, which is a kind of *Convonvulus* or blew Bellflower, whereof I have ſpoken in my former Booke, which *Serapio* calleth *Hab alnil granum nil*: but this *Nil* (for *Nir* in the *Arabicke* tongue, as ſome ſay doth ſignifie any blew colour, ſuch as this Woade or the *Nil* or *Indico* maketh) or *Anil*, from whence was made a blew colour formerly called with us Aneale for the Dyers and others uſe, and was wont to be brought in round great cakes like wax, with round bottomes five or ſix packt up in double skinnes longwiſe, which was but a baſe or counterfeit ſort of *Indico*, (as it is probably gheſſed) made up with ſand and traſh to augment the weight; or elſe it was a worſer kinde of that *Nil* or *Anil* that grew in *Turkey*; for the beſt *Nil Anil* or *Indico* as is aforeſaid commeth to us from *Guzurate* in the Eaſt *Indies*; *Ioſeph Salbanke* his report of *Indico* in *Purchas lib.3.ch. 9. ſec.4.pag.236.* (who by reaſon of ſhipwracke upon the *Magolls* countrey, with others was forced to travell over-land many dayes) ſaith that at *Bianie* the beſt *Indico* is made, where are *Indico* milles and groweth upon ſmall buſhes, and beareth ſeede like Cabbadge ſeede, which being cut downe lyeth on heapes for halfe a yeare to rot, and then troden out by Oxen from the ſtalkes and ſo ground fine at the milles, and laſtly boiled in furnaces, refined and ſorted, the beſt there worth eight pence the pound: which laſt clauſe of boyling refining, &c. me thinkes ſavoreth ſomewhat of *Dioſcorides* text, (but you have another mans report before) *Dioſcorides* mentioneth *Indicum* in his fifth booke and 67. Chap. to be of two ſorts, the one naturall iſſuing out of *Indian* Canes or Reeds: the other a blew or purple ſcumme that riſeth on the dyfat, which is taken off and dryed: this ſaith *Dioſcorides*, and peradventure was our very *Indico*, although related it may bee in this manner, which ſheweth how lame the ancients were in the knowledge of forraine doings: but we have indeede, even in theſe dayes, a certaine thing called by divers *Florey*, which the painters ſometimes uſe, and is the ſcumme of the dyfat, while the cloth is upon the dying a blew colour with *Indico* or Woade, and is a fine light powder. The *Italians* as I ſayd before call Woade *Guado* and *Glaſto*; the *Spaniards* call the herbe while it is greene and growing *Guida*, but when it is made up and dry, they call it *Paſtel*, *forte quia in paſtillos cogantur*, the *French Paſtel* likewiſe, the *Germans Weijt*, the *Dutch Weet*, we in *Engliſh* Woade and Wade.

The Vertues.

The faculties of Woade are binding and very drying, and ſomewhat bitter withall, but not ſharpē, and thē wilde ſort much more, as uſually all wilde herbes exceede the tame in the properties, and therefore it reſiſteth putrefaction, and preſerveth therefrom more then the tame: the tame ſtancheth bleedings of all ſorts, eyther inward or outward, eyther upwards or downewards more then the wilde: the decoction of the manured, but much more of the wilde ſort, made with wine and drunke, helpeth the hardneſſe of the ſpleene; and if the region thereof be outwardly fomented therewith alſo, it will doe the more good: the manured is much more profitably uſed for all greene wounds then the wilde, quickly to ſoder up the lippes of them, and no leſſe profitable it is to repreſſe the corroding and malignant qualities of fowle and eating Vlcers, foule Cancers and the like, and healeth them alſo; as alſo allayeth and diſcuſſeth all hot inflammations, impoſtumes, S. *Antonies* fire, hard tumours or ſwellings. *Indico* (which as is ſayd, was formerly taken for the ſpume of the dyfat, in dying a blew colour, either from Woade or *Indico*) as *Dioſcorides* ſaith is of the ſame qualities, both to clenſe and repreſſe the malignitie of foule Vlcers, and to diſſolve tumours, breake impoſtumes, and to dry up and binde the defluxions of blood or humors: the juice of Woade preſerved all the yeare, or the diſtilled water of the herbe, worketh the ſame effectes that eyther the decoction or the powder of the dryed herbe doth.

CHAP. LXIIII.

Herba Lutea ſive Luteola. Would or Welde or Diers weede.

I Thought good to joyne this plant unto the other before going, both for the dying quality and healing alſo, although not ſo notorious as the other: but although with many former writers, there hath beene but one ſort remembred, yet we have attained the knowledge of two or three other as you ſhall have them expreſſed unto you.

1. *Luteola vulgaris.* Common Would or Diers weede.

The common Would or Diers weede groweth buſhing with many long and narrow flat leaves upon thē ground, of a darke blewiſh greene colour, ſomewhat like unto Woade, but nothing ſo large, a little crumpled as it were and ſomewhat round pointed, which doe ſo abide the firſt yeare; and the next ſpring from among them riſe divers round ſtalkes, two or thee foote high, beſet with many ſuch like leaves thereon, but ſmaller, and ſhooting forth ſome ſmall branches, which with the ſtalkes carry many ſmall yellow flowers, in a long ſpiked head at the toppes of them, where afterwards come the ſeede, which is ſmall and blacke, encloſed in heads that are divided at the toppe into foure parts: the roote is long, thicke and white, abiding the winter: the whole herbe changeth to be yellow, after it hath beene in flower a while.

2. *Luteola vulgaris Cretica.* Small Would of *Candy*.

The ſmall Would of *Candy* hath likewiſe many long narrow leaves like the former, and tall high ſtalkes with ſmaller leaves on them alſo: the long ſpiked heads have ſomewhat larger flowers, more ſpread open and ſtanding ſingly each by themſelves, in other things not differing from the former.

3. *Lutea maxima Cretica fœcunda.* The bearing great Would of *Candy*.

This great plant riſeth up in *Candy*, with divers great ſtalkes, ſome of them as bigge as a mans arme of five, ſix, eight and ten cubits high, yet periſh in winter, bare or naked of leaves next the ground for a cubits ſpace, the loweſt leaves being without footeſtalkes joyning cloſe at the bottome, the other growing up higher up to the toppes, have all of them footeſtalkes of a ſpanne long: the leaves of themſelves are very large, made of many ſomewhat broad and long greene ſhining ones, ſet one againſt another on the middle ribbe, and not yet alwayes directly

directly oppoſite one unto another, every one ſomewhat like unto the leaves of Hempe (whereof it is moſt likely to be a *ſpecies*) ragged or dented about the edges, yet none of them divided but the end leafe, which is ſometimes divided, ſeldome into two, and ſometimes into three parts, each ending in a long point; the ſtalkes are branched, but hath onely divers ſmall ſtalkes, or long ſpikes of flowers thruſt forth which are yellowiſh, greene and moſſie, bowing downewards, with many long and narrow leaves among them, and ſtand in yellowiſh greene huskes; wherein, after the flowers are fallen, come the heads full of very ſmall reddiſh ſeede: the roote is very great and wooddy, and parted into many long armes or branches, which in the naturall places, and other warme countries, abideth many yeares, but will hardly endure the winters of our cold countrey abroad as we have often proved.

4. *Lutea maxima Cretica ſterilis.* The barren great Would of *Candy*.

There is no difference in this from the other, but that as Hempe and Mercury, and ſuch like plants, one beareth ſeedes, and the other doth not, ſo this although it beare flowers, yet no ſeede is ſeene to follow at any time after as is in the former.

The Place.

The firſt groweth every where by the way ſides, in moiſt grounds as well as dry, in corners of fields and by-lanes; in ſome places in *Kent*, they uſe to ſow their fields therewith after their Barley, which abideth untill the next yeare, and then is gathered; the reſt are naturall of *Candy*, and as I ſayd will hardly indure, or at the leaſt beare in our climate.

The Time.

The firſt is in flower about *Iune*, but the others flower very late or not at all with us.

1. *Lutea vulgaris.* Common Would, or Diers Weede.

2. *Luteola vulgaris Cretica.* Small Would of *Canay*.

3. 4 *Lutea Cretica fertilis & ſterilis.* The great Would of *Candy* both bearing and barren.

The Names.

There is not any Greeke name knowne to be given unto it. *Pliny* maketh mention of it in his 33 booke, and 5. chap. and calleth it *Lutea*, yet *Bauhinus* referreth it to the *Geniſta tinctorum* Greeneweede. *Vitruvius* alſo in his 7. booke of Architecture, and 14. chap. calleth it *Luteum*, and *Virgill* calleth it *Lutum*, in the 4. *Eclog* of his *Bucolickes* in theſe verſes,

Ipſe ſed in pratis, aries jam ſuave rubenti
Murice, jam creceo, mutabit vellere Luto.

It is called alſo by ſome *Luteola*; and by ſome alſo thought to be the *Reſeda* of *Pliny*, becauſe they agree ſo well in divers parts. *Cæſalpinus* in his ninth booke, and 35. chap. maketh it to be the *Myagrum* or *Melampyrum* of *Dioſcorides*, and calleth it according to the peoples terme in his time, *Guadarella*: It tooke the name of *Lutea*, not onely of the yellow colour of the herbe and flowers, when it is dry, but chiefely from the yellow colour in the dye. *Tragus* tooke it to be *Antirrhinum*, becauſe the ſeede veſſels thereof have as it were holes therein. Some have taken it alſo to be *Phyteuma* of *Dioſcorides*, and ſome to be his *Struthium*, among whom are *Lacuna*, and *Geſner in hortis Germaniæ*: but *Matthiolus* calleth it *Pſeudoſtruthium*: *Dodonæus* calleth it *Herba Lutea*, *Lobel Luteola*, *Lonicerus* and *Tabermontanus Catanance*. The Second is thought by *Honorius Bellus*, in his ſecond Epiſtle to *Cluſius*, to be the true *Struthium* of *Dioſcorides*, and ſaith that it is called *Cumene* throughout all Greece: but *Camerarius in horto*, ſeemeth to make it and the common ſort all one, the third and fourth are remembred by *Pona*, the one in his Latine, and both in his *Italian* Edition more exactly.

The Vertues.

Matthiolus ſaith, that the roote hereof, is hot and dry in the third degree, and that it cutteth tough flegme, it maketh groſſe humours thinne, it doth reſolve hard tumours, it digeſteth raw flegme, and openeth obſtructions. Some doe not onely commend it, againſt the bitings of any venemous creatures, to be applyed as well outwardly to the wound or hurt place, as to be taken inwardly, to expell the poyſon therhence: but alſo much commended it to be uſed againſt the Plague or Peſtilence; the people in ſome Countries of this Land, doe uſe to bruiſe the herbe, and lay it to the cuts or wounds, they chance to make in their hands, or legges, &c. the chiefeſt uſe otherwiſe they have thereof, is to dye cloth, either wollen or linnen, or ſilke, raw or woven into a yellow colour, and alſo to give a greene colour to thoſe clothes or ſilkes, have firſt beene dyed with Woade, into a blue colour, which *Vitruvius* it ſeemeth was not ignorant of in his time, for he ſpeaketh thereof in the aforeſayd place, both booke and chapter, that a yellow colour upon a blue, is changed into greene, and for theſe uſes, there is great ſtore of this herbe ſpent in all Countries, and thereof many fields ſowen for the purpoſe.

Chap. LXV.

Lamium. The Dead Nettle or Archangell.

THe word *Lamium* which we call dead Nettle or blind Nettle, is diverſly taken by divers, for ſome doe make it a Nettle, and number it among their kinds; others make it a kinde of *Galeopſis*, as beſides others *Bauhinus* who confoundeth them together, maketh thoſe herbes to be *Lamia* that *Cluſius*, and others make to be *Galeopſis*, *& e converſo*; ſome alſo make them to be kinds of *Scrophularia*, and ſome thoſe to be *Lamia*, which others call Chickeweedes and Balme, which are all in my judgement ſeverall herbes, and to be handled ſeverally: for which purpoſe I will endeavour what in me lyeth, ſo to diſtinguiſh them, that each ſhall have their owne due: and if I ſhall not herein perhaps ſatisfie every one, for *quot homines, tot ſententiæ*, yet I ſhall ſatisfie my ſelfe, who I am perſwaded ſhall not want many partakers; and yet I cannot, nor doe challenge any prerogative of not erring in ſo intricate a buſineſſe, where ſo many learned writers have failed before me: take therefore in good part what I here ſet downe, and if any finde fault with any of them to be miſplaced, let them amend it, by true judgement not worthy of fault finding, and I ſhall ſoone ſubſcribe unto them.

1. *Lamium vulgare folio ſubrotundo flore rubro.* Red dead Nettle or red Archangell.

This Dead Nettle, or Archangell, hath divers ſquare ſtalkes ſomewhat hayrie, at the joynts whereof ſtanding a good diſtance one from another, grow two ſad greene leaves, dented about the edges, oppoſite the one to the other, the lowermoſt upon long footeſtalkes, but without any towards the toppes, which are ſomewhat round, yet pointed at the ends, and a little crumpled as it were and hayrie; round about the upper joynts, with the leaves which there grow cloſe together, grow ſundry gaping flowers, of a pale reddiſh colour, ſomewhat like unto Betony flowers, after which come the ſeedes, three or foure ſet together in a huske: the roote is ſmall and threddy periſhing every yeere: the whole plant, hath a ſtrong ſent, but not ſtincking.

2. *Lamium Hiſpanicum.* *Spaniſh* Archangell.

This *Spaniſh* kinde hath darke browne ſquare ſtalkes, riſing halfe a foote high, bearing two ſmall and almoſt round leaves at each joynt, reſembling the former red common Archangell: the tops of the ſtalks and branches are thicke ſet with flowers, ſpike faſhion, without any leaves among them, which before they open are ſhort and cloſe, helmet like, but afterwards growing long and ſlender toward the bottome, the toppe or end becomming hooded and gaping of a purpliſh red colour; in the bottome huskes afterwards ſtand foure white ſeedes: the roote is thicke at the head with ſundry ſmall fibres, but creepeth not as others doe, abiding many yeares: the whole plant ſmelleth like the ordinary Archangell.

3. *Lamium vulgare album ſive Archangelica flore albo.* White Archangell.

The white Archangell hath diverſe ſquare ſtalkes, not ſtanding ſtraight upright, but leaning downewards to the ground, whereon ſtand two leaves at a joynt, larger and more pointed than the other, dented about the edges, and greener alſo, more like unto Nettle leaves alſo than the former, but not ſtinging although ſomewhat hayrie: at the joynts with the leaves ſtand larger, and more open gaping white flowers, in huskes round about the ſtalkes, but not having ſuch a buſh of leaves and flowers, ſo cloſely ſet at the toppes, as in the former, wherein ſtand ſmall roundiſh blacke ſeede, after they are fallen: the roote is white with many fibres thereat, not growing

downe-

1. *Lamium vulgare flore rubro.*
Red dead Nettle or Archangell.

2. *Lamium Hispanicum.*
Spanish Archangell.

3. *Lamium flore albo.*
White Archangell.

6. *Lamii montani Columnæ duæ species.*
The two sorts of Mountaine dead Nettles of *Columna.*

downeward, but lying under the upper cruſt of the earth, ſpreading and encreaſing like unto Couch-graſſe, which abideth many yeares ſtill encreaſing, this hath not ſo ſtrong aſent as the former.

4. *Lamium folio oblongo flore rubro.* Long leafed red Archangell.

Of this ſame kinde there is one found in ſome places of this Land, agreeing with this laſt in all things, but in the flowers, which are of a purpliſh red colour; and another whoſe flowers are more pale red, and the lippes with whitiſh veines; but are rare to be met withall, but in ſome places, where there is almoſt no other kinde; and hath no ill ſent.

5. *Lamium foliis maculatis.* Archangell with ſpotted leaves.

The ſpotted Archangell is alſo very like the former, in the forme of the leaves and flowers, but ſomewhat larger; in the manner of growing it is lowet and more creeping: the chiefe difference herein is, that in all the leaves, there are certaine markes or ſpots, and ſome ſmall ſhort lines to be ſeene in them, whereby it is diſtinguiſhed from the former.

6. *Lamium Plinij montanum Columnæ.* Archangell with white lines in the leaves.

This Archangell *Columna* hath well obſerved to differ from the laſt, firſt in the leaves being larger, and dented about with rounder dents, and then in the white lines therein, which in this runne ſtraight forth, and ſomewhat large on each ſide the middle ribbe, and not ſpotted or ſtraked as in the laſt, which white lines they will hold conſpicuous many yeares, after they have beene dryed, whereas the other, either fade altogether or are hardly to be diſcerned, within a yeere after they are dryed: and laſtly in the flowers which in this, are of a paler red, tending to a bluſh colour. *Columna* ſetteth forth another ſort hereof, with ſmaller and deeper dented leaves, whoſe white lines in the middle of the leaves, are not ſo broad, nor differing in any thing elſe.

Alterum montanum ejuſdem.

7. *Lamium luteum.* Yellow Archangell.

The yellow Archangell, in the ſquare ſtalkes, and large greene dented leaves, is like the white Archangell, but that the ſtalkes are more ſtraight and upright, not bending downewards, and the joynts with leaves are more ſeparate in ſunder, having longer leaves than the former: the flowers alſo are a little larger, and more gaping; of a faire yellow colour in moſt, and in ſome more faint: the rootes hereof I have not found to creepe under ground, ſo much as the white, but elſe very like thereunto.

8. *Lamium peregrinum Scutellaria dictum.*
Strange Archangell.

This ſtrange gaping Archangell, ſhooteth forth in the beginning of the Spring, a ſquare hayrie ſtraight ſtalke, about a cubit high, at the joynts whereof, are ſet the leaves by couples, which are ſomewhat long and deepely indented about the edges, of a ſad greene colour, ſmooth, and a little hayrie withall, ſtanding upon long hayrie footeſtalkes: about the middle of the ſtalke come forth divers branches on all ſides, about an hand breadth long, ſet with narrower and longer pointed leaves, not dented at all; at the toppes whereof and the ſtalkes ſtand long ſpiked heads of purpliſh flowers, like unto the Archangells, before deſcribed, and in ſome white, but longer and more open, two ſometimes ſtanding in one huske, and with a hood or helmet at the head of them; wherein after they are fallen, are ſet foure rough ſeedes, round and flat, very hayrie, clammie, and ſweete, ſticking to the fingers, while they are freſh: at the toppes of every one whereof, there is a cleft like a mouth, and about that a crowne like unto an Helmet: the roote is yellowiſh and ſtringie not periſhing.

Flore albo.

7. *Lanium Luteum.*
Yellow Archangell.

The Place.

All theſe Archangels grow wilde, ſome of the firſt ſorts by wall ſides, and the borders of fieldes, and way ſides, almoſt every where with us: the yellow moſt uſually in the wet grounds of Woods, and ſometimes in the dryer, in diuers Countries of this Land: thoſe with white ſpots and lines, are very rare to meete with in our Kingdome, but the fift in *Germany* as *Thalius* ſaith, and in *Italy* as *Matthiolus* and *Columna* ſay, very plentifully; the two ſorts of the ſixth in *Naples* onely as *Columna* ſaith: and the laſt in *Candy* as *Pona* ſaith and in *Naples* as *Columna* ſaith.

The Time.

They flower from the beginning of the ſpring, all the Sommer long.

The Names.

The name *Lamium* was firſt taken from *Pliny*, who after he had ſpoken of Nettles, ſaith that the Nettle that ſtingeth not, and is not hurtfull, is called *Lamium*. It is called *Vrtica iners, non mordax, & mortua, quia foliis non mordacibus ſed mitiſſimis ſit*, and *Archangelica* of ſome, *ab eximijs viribus*; and *Lamium fortaſſe a florum figura, veluti cucullo larvatam lamiam quandam repreſentante*. The firſt is called by *Lobel*, *Vrtica non mordax*, *Vrtica mortua*, and *Galeopſis vulgaris fœtens purpurea*; *Lugdunenſis* ſaith, there is no other herbe that commeth nearer to the deſcription of *Dioſcorides* his *Galeopſis*, then this, which *Bauhinus* alloweth of, calling it *Lamium purpureum fœtidum folio ſubrotundo*, *Galeopſis Dioſcoridis*, and ſaith, that *Cordus* upon *Dioſcorides*, *Cæſalpinus* and *Tabermontanus*, underſtood this *Lamium*, to be the *Galeopſis* of *Dioſcorides*, but I doe not finde that this kind was knowne unto them; but that it is the other red Archangell, with longer leaves that is more like unto the white, or the yellow,

yellow Archangell which they meant; and *Clusius* as you shall heare by & by, misliked all other figures of *Galeopsis* as not truly answering unto *Dioscorides* his description, for I can finde no Author hath given a true figure hereof before *Lobel* and *Dodonæus*; whereby it seemeth that this *Lamium* is more proper to England then to other countries. *Dodonæus* calleth it *Urtica iners altera*. I would incline to think this kind of *Lamium* to be the true *Galeopsis* of *Dioscorides* with *Lobel* and others, if the leaves were not so round, but more like unto Nettle leaves, and that we had not a kinde, that smelleth strong, with leaves more like unto the Nettle, as you shall heare in the next Chapter. And I would rather thinke also, that the other red Archangell that hath longer leaves very like the white were the *Galeopsis* of *Dioscorides*, with *Matthiolus*, *Lacuna*, *Cordus* and the rest, if it had a strong sent which it hath not, so that seeing both these are defective eyther in the one or the other quality, I cannot deeme eyther of them to be right, especially seeing I can produce one that hath both these properties more answerable to *Dioscorides* his description. The second is remembred onely by *Cornutus* in his history of *Canada* plants, and there called *Lamium Astragaloides*. The third is the first *Lamium* of *Dodonæus*, called by *Lobel* *Archangelica flore albo*, from whence came our *English* word Archangell, as I take it. The fourth is as I sayd, the *Galeopsis* of *Matthiolus*, *Lugdunensis* and others that follow him, *Tabermontanus* called both these sorts *Lamium purpureum & album*. *Cæsalpinus* calleth them *Leucas*, and are his second and third; *Bauhinus* calleth them *Lamium purpureum vel album, non fœtens folio oblongo*. The fifth *Thalius* calleth *Urtica fœtua* λαμιόειδὴς, and is *Tabermontanus* first *Galeopsis*, which *Columna* calleth *Urtica mortua maculis albis respersa*, and of *Bauhinus* *Lamium maculatum*. The sixt is the *Lamium Plinij* of *Anguillara*, *Camerarius* and *Matthiolus*, and by him called *Vrtica lactea*, who would faine have made it the *Galeopsis* of *Dioscorides*, but that he found *Pliny* to make mention of the white in the leaves of *Lamium*, to be especially used for inflammations, S. *Anthonies* fire and the like, which made him desist from that opinion, and conclude it *Plinies Lamium*. *Columna* calleth it *Lamium Plinij montanum*, and *Bauhinus* *Lamium alba linea notatum*; and this he saith the *Italians* call *Milzadella* or *Milzatella*, which is so highly commended by them against the spleene: but *Lobel* taketh the ordinary white, or the yellow Archangell to bee it, and so doth *Lugdunensis* also, and both erroniously: The seaventh is called *Lamium luteum* by *Lobel*, *Dodonæus* and others; *Galeopsis flore luteo* by *Camerarius*, and *Dalechampius*. *Cæsalpinus* calleth it *Leucoium montanum*: the last is called *Cassida* by *Columna*, and *Scutellaria* by *Cortusus*, and those of *Italy*, as well at *Padoa* as at *Naples*. *Bauhinus* calleth it *Lamium peregrinum sive Scutellaria*, and saith that it is the *Scordotis secunda Plinij* of *Pona*, in his *Italian* description of Mount *Baldus*, which I hardly beleeve, because the flowers are not equall, according to their figures; as also that *Betonica sylvestris* of *Paulus Ægineta*, that is like Pennyroyall and without sent, whereof I speake in the Chapter of Betony hereafter, by *Quadramius* judgement is this kind of *Lamium*: the *Italians* call it *Ortica morte*, the *Spaniards Hertiga muerta*, the *French Ortie morte*, the *Germanes Todt Nessell*, *Taub Nessell*, and *Binsang*, the *Dutch Doove Nettlen*, and wee in *English*, Dead Nettle, Blind Nettle, and Archangell.

The Vertues.

The Archangells are somewhat hotter and drier then the stinging Nettles, and are more appropriate, and with better successe used for the obstructions and hardnesse of the spleene then they, to be used inwardly by drinking the decoction of the herbe in wine, and afterwards applying the herbe hot, or the decoction unto the region of the spleene, as a cataplasme or fomentation with spunges. The flowers of the white Archangells are preserved or conserved daily to be used, or the distilled water of them is used to stay the whites, and those of the red to stay the reds in women, and is thought good to make the heart merry, to drive away melancholly, and to quicken the spirits. It is commended also against quartaine agues. It stancheth bleedings also at the mouth or nose; if the herbe be stamped and applyed to the nape of the necke: the herbe also bruised and with some salt and vinegar, or with *Auxungia* that is, Hogs Lard laid upon any hard tumour or swelling, and that in the neck or throate, which is called the Kings Evill doth helpe to dissolve, or discusse them: in the like manner applyed to the Goute, Sciatica or other joynt aches or of the sinewes, doth very much allay the paines, and give ease. It is also very effectuall for all inflammations, as a repercussive, and to heale all greene wounds, by drying and closing up the lippes of the wounds, and for old Vlcers also to stay their malignitie of fretting, and corroding or spreading, thereby causing them to heale the more speedily: it draweth forth splinters, or other such like things gotten into the flesh. *Pliny* highly commendeth it for many other things, as for bruises and burnings: but the Archangell with yellow flowers is most commended, for old filthy and corrupt sores or corrupt Vlcers, yea although they grow to be fistulous or hollow, and to dissolve tumors.

CHAP. LXVI.

Galeopsis. Stinking Dead Nettle.

I Have here to bring to your consideration not onely the Genuine *Galeopsis* of *Dioscorides*, both in *Clusius* and my judgement, but some other plants also, which may not unfitly for their likenesse thereunto, be referred unto it as I thinke.

1. *Galeopsis genuina Dioscoridis.* The true stinking Dead Nettle of *Dioscorides*.

This kind of Dead Nettle hath divers square, soft, and hairy stalkes, rising up to be three or foure foote high, at the joynts whereof grow two leaves a peece upon long footestalkes, very like unto Nettle leaves, but that they are soft and somewhat hoary or hairy, but not stinging at all, of a very strong sent somewhat unpleasant, especially growing in shadowy places, and nothing so strong in the open fields: at the toppes of the stalkes grow the flowers set in rundles, foure or five at a space, and many of them one above another, in manner of a spike, every one standing in a greenish huske, like unto those of the former Dead Nettles, but not so great and are of a sad red or purplish colour, especially the heads or upper parts; but the lower labells or lippes, have some white spots in them: within those huskes after the flowers are fallen, grow small round, yet somewhat rough seede, foure for the most part standing together: the roote is composed of many strings, shooting fresh heads every yeare, and increasing thereby very much.

2. *Galeopsis*

2. *Galeopsis altera incana.* Hoary stinking Dead Nettle.

This other Dead Nettle hath shorter square stalkes soft and hoary, very slender and weake, creeping as it were by the ground, with two leaves set at the joynts likewise soft and hairy, and more hoary underneath, not so large as the former: the toppes of the stalkes end in a long spike or purplish flowers, set in roundles as in the other; the seede and roote is also answerable unto the other.

3. *Galeopsis lutea Dalechampij.* Yellow stinking Dead Nettle.

The yellow Dead Nettle hath square low stalkes not above a cubit high, with long leaves set thereon by couples, very like unto Nettle leaves, smaller below next the ground then up higher upon the stalkes being hairy, but not stinking, and smelling somewhat strong like the first: the flowers grow in long spiked heads in the same manner, but are all yellow when they are fully blowne, consisting of two leaves, the uppermost whereof is not so much hooded as the former, but is as it were a cover to the lower, and turneth it selfe up againe, having some yellow threds in the middle, but while it is in budde is somewhat reddish: the seede is set in huskes as the other, the roote is threddy and blackish like the former.

4. *Galeopsis altera pallida.* Pale *Galeopsis* or stinking Dead Nettle.

This hath sundry pale greene broad leaves set on long hairy footestalkes: the stemme is square and hairy also, with such like but lesser leaves thereon, and sundry small pale yellowish flowers set together at spaces, which turne into small round and pointed heads, with small blackish seedes in them; it smelleth strong or stinketh as bad as the rest.

5. *Galeopsis maxima Pannonica.* The Dragon flower.

This I have described in my former booke whereunto I must referre you, although I give you the figure thereof here.

1. *Galeopsis legitima Dioscoridis.* Stinking Dead Nettle.

4. *Galeopsis altera luteo pallida.* Pale coloured *Galeopsis* or stinking Dead Nettle.

5. *Galeopsis maxima Pannonica.* The Dragon flower.

The

The Place.

The first is very frequent in our land, in divers countries, as at *Hampsted* going from the towne to the Church, and many other places from *Hampsted* heath to *London*: the second and third I have not knowne grow wilde, but onely in our gardens: the fourth *Cusius* saith he found growing naturally in his garden at *Vienna*, and so did I likewise in my garden in Long Acre, not knowing otherwise of any such seede was sent me, for it grew not in any of my sowen beds, but straglingly in wast places.

The Time.

All these sorts are in flower both in *Iune* and *July*; for the most part, and the seede is quickely ripe after the flowers are past.

The Names.

It is called in Greeke as *Dioscorides* saith γαλίοψις, γαλέοψις, & γαλέοβδολον, *Galiopsis, Galeopsis, & Galeobdolos, a galeata florum effigie*, as some thinke, or as *Matthio'us* saith, *a* γάλα & ὄψις, and then he would adapt the *Lamium Plinij maculatis foliis* unto it, but himselfe disclaimeth that deduction, and the other is not right, for the word γαλεοβδολον, which signifieth *mustela fœtida*, sheweth the truer derivation as *Pliny* hath it *a florum figura, mustelæ faciem & rictum quadantenus exprimente*: It is called usually in Latine also *Galeopsis*, as *Pliny* doth more truly, then *Galiopsis*, and *Urtica mortua fœtida, & Urtica labeo*, of the great lippes in the flowers. The first is from *Tragus* called usually *Urtica Heraclea*, or by others *Herculea Tragi*: of *Lonicerus Urtica sylvana*, of *Clusius Galeopsis legitima Dioscoridis*, but by *Bauhinus Lamium maximum sylvaticum fœtidum*: the second is the *Lamium incanum* of *Thalius*, and the *Galeopsis rubra* of *Lugdunensis*, whereof he saith there groweth plenty in the groves above *Lyons*, as well as the other yellow *Galeopsis*; whereof neither as he saith, is any *Lamium*, either stinking, or not smelling, for as he saith this red differeth from the yellow, onely in the colour of the flower, both of them bearing spiked heads like the first: the third is *Lugdunensis Galeopsis lutea Dalechampij*, called *Galeopsis flore luteo folio oblongo*, and *rectis caulibus* of *Camerarius in horto*, differing from the *Lamium luteum*, for he mentioneth it also among the other *Lamia*: the fourth *Clusius* calleth *Lamium Pannonicum secundum sive exoticum*, and is thought to be *Scrophularia flore luteo* of *Bauhinus*, as you shall finde it noted in the chapter of *Scrophularia* afterwards: but surely it hath little correspondency with the *Lamia*.

The Vertues.

The stincking Dead Nettles, any of the kinds of them, boyled in wine and drunke, doth wonderfully helpe all inward wounds and hurts, bruises, falls or the like, and are singular good also for the spleene, and the diseases thereof: but especially for the hemorrhoides or piles, when they are painefull being swollen and fallen downe: the juyce thereof applyed warme with vinegar, both easeth the paines and draweth forth the blood: and in the same manner used helpeth the warts, and other such like hard grumes or knots, that grow in and about the fundament; as also all other manner of hard swellings, as wennes, warts, and kernels, that grow in the necke or throate, or in any part of the body; it is singularly commended for all manner of filthy ulcers, gangrenes, and cancers, be they corroding or fistulous.

CHAP. LXVII.

Scrophularia major. Great Figwort.

THere are two sorts of *Scrophularia* or Figge-wort, as they are so called by divers, a greater and lesser, the lesser being called *Chelidonium minus*, whereof I shall entreate hereafter: but of the greater in this Chapter, whereof there are divers other sorts that formerly were not knowne.

1. *Scrophularia major vulgaris.* The ordinary great Figgewort.

The common great Figgewort sendeth forth divers great, strong, hard, square, browne stalkes, three or foure foote high, whereon grow large, hard, and darke greene leaves, two at a joynt, which are larger, and harder than any Nettle leaves, but not stinging, very like unto the leaves of Water *Betonie*, so that they are sometimes mistaken, being somewhat hardly discerned one from the other, but that these are not so round dented about the edges, and are also smaller at the ends; at the toppes of the stalkes, stand many purple flowers, set in huskes, which are somewhat gaping and open, but not so much as any of the former dead Nettles, but closer and smaller, somewhat like those of Water *Betony*, after which come hard round heads, with a small point in the middle, wherein lye small browniſh seede: the roote is great white and thicke, with divers knobbes or bunches at it, growing a slope, under the upper crust of the ground, and abideth many yeeres, but keepeth not his greene leaves in the winter.

There is another sort hereof very like in leaves, but more sometimes standing at a joynt, especially the lowermost, the flowers are not gaping, but made of foure reddish leaves, which usually stand at the joynts with the leaves: the seede vessels are not pointed. *Scrofularia major altera elegans.*

2. *Scrophularia altera Ruta Canina dicta.* Great Figge-wort without knobbed rootes.

This other kinde of great Figge-wort, riseth up with many weake and tender stalkes, not above two foote high, whereon grow narrow, long, and somewhat thicke darke greene leaves, cut in on the edges on both sides into divers parts, making them seeme like the leaves of wilde field Poppie, smelling somewhat strong like Rue, or Poppie, and set without order, sometimes but one or two, and sometimes more standing at a joynt; the flowers are many but smaller, of a darke or sad purple colour, somewhat like the other, or like unto Toadflaxe, standing many together, upon severall small branches at the toppes of the stalkes, which smell as strong almost as the leaves: after which come small heads like the former, the seede whereof is not much unlike: the roote hereof hath no knobs thereat at all, but consisteth of a long, downeright bigge roote, with many small fibres growing to it.

3. *Scrophularia Cretica latifolia.* Great leafed Figge-wort of *Candy*.

This Figge-wort of *Candy* hath a square cornered greene stalke, browniſh on the side next the Sunne: at the bottome whereof grow divers large, and long winged leaves, set upon their foote stalkes, made of many parts, some-

1. *Scrophularia major vulgaris.*
Ordinary great Figge-wort.

Scrophularia major altera elegans.
Another dainty great Figge-wort.

2. *Scrophularia altera Ruta Canina dicta.*
Great Figge-wort without knobbed rootes.

3. *Scrophularia Cretica latifolia.*
Great leafed Figge-wort of *Candye.*

ſomewhat like the laſt, but larger and more cut in on the edges, and each part cut in on their edges likewiſe, making every leafe ſeeme like unto a Ferne, or the leafe of the red Rattle; from the middle of the ſtalke, ſhoote forth round about it, up to the toppes almoſt, other branches, and they againe ſome ſmaller, having on all ſides ſuch like leaves, but leſſer than grow below, ſet thereon; and at the toppes of the ſtalkes and branches, are many ſmall flowers, ſet ſomewhat like unto the firſt ordinary Figge-wort, but part of a deeper and part of a paler purple colour, with ſome yellow threds, riſing out of the middle: the roote is of a fingers thickeneſſe, and divided into diverſe other parts.

4. *Scrophularia peregrina.* Strange great Figge-wort.

This ſtrange Figge-wort beareth divers ſquare browne ſtalkes, riſing from the roote about two foote high, whereon grow without any order, many ſoft leaves like Nettles, but not pricking or ſtinging at all, ſomewhat longer alſo and deeper cut in on the edges, eſpecially in ſome of them, of a darke greene colour on the upperſide, and greene underneath: the ſtalkes branch themſelves into many other ſmaller ones, with leaves on them to the toppes, like the lower but leſſer, where ſtand many darke purple flowers, whoſe upper leaves turne upwards, and the lower fall downe like lippes, each of them ſtanding in greene huskes, that are parted into five points; wherein after the flower is fallen and paſt, commeth a round head, divided as it were with a ſeame into two parts, with a little point at the end, wherein lye ſmall browniſh ſeede, like the common ſort: this alſo hath a ſtrong ſent, rather worſe than the laſt.

5. *Scrophularia peregrina altera.* Another ſtrange great Figge-wort.

The ſtalke hereof is about two foote high: the leaves are of a faire greene colour, as it were winged, the flowers are yellowiſh, with pale threds in the middle: the ſeed is ſmall in round huskes being by-forked at the ends.

6. *Scrophularia flore luteo.* Yellow Figge-wort.

The yellow Figge-wort bringeth forth diverſe ſquare browne ſtalkes, ſomewhat hayrie and ſoft, about two foote high, at the joynts whereof grow two large broad, round, hayrie, ſoft greene leaves, deepely dented about the edgeſs, ſtanding upon very long footeſtalkes, thoſe at the foote of the ſtalkes being largeſt, which in winter lye in a compaſſe upon the ground, round about the roote; and thoſe on the ſtalkes leſſer and leſſer up to the toppes: at each joynt with the leaves commeth forth, even almoſt from the bottome, one ſmall naked branch, bearing many flowers in tufts at the ends of them, which are round and yellow, ſomewhat like the ordinary ſort, parted or cut in at the brimmes, into ſeverall peeces, having ſome long yellowiſh threds in the middle: after the flowers are paſt, come larger round heads than in the former, whoſe point at the end is long, and a little crooked, containing within them ſmall blacke ſeede: the roote is thicke and blackiſh, with many ſtrings and fibres thereat, but not having any knobbes thereon at all.

7. *Scrophularia Indica.* Indian Figge-wort.

The Indian Figge-wort, hath divers thicke but weake branches, lying all about upon the ground, full of joynts;

5. *Scrophularia peregrina alcera.*
Another ſtrange great Figge-wort.

8. *Scrophularia Sambucifolia.*
Elder-like Figge-wort.

with large and long, darke greene leaves, cut in on the edges, into five long diuiſions, all of them dented about the edges, and from the ſame joynts come forth alſo other leſſer leaves, divided and dented, and with them toward the toppes of ſtalkes, divers large flowers of a yellowiſh colour on the out ſide, and lower part; but within of a reddiſh colour, mixt with the yellow: after which come larger and harder heads, than in any of the former by much, pointed at the end as the reſt, and within them ſmall blackiſh ſeede: the roote is thicke and buſhie, but periſheth in the winter, if it riſe up to flower, elſe abiding.

8. *Scrophularia Sambucifolio.* Elder-like Figge-wort.

This Figge-wort riſeth up with divers ſquare hollow ſtalkes, two or three cubits high, with ſundry winged leaves, iſſuing from the joynts thereof, conſiſting of many, ſet one againſt another, upon a middle ribbe neere reſembling an Elder leafe, and ſmelling ſtrongly thereafter: the branched ſtalkes beare the like leaves, and at the joynts with them, and at the toppes ſtand many hollow flowers, hanging downe their heads round about the ſtalkes, of a browniſh red or purple colour, after which come ſmall round blacke ſeede veſſels, pointed at the ends with the like ſmall ſeede in them as in others: the roote is ſomewhat long, with divers fibers thereat.

The Place.

The firſt is very frequent in all places of this Land, both in moyſt and ſhadowie woodes, and in the lower parts of fieldes, and meddowes: the ſecond *Lobel* ſaith, groweth not but in the warme Countries of *Narbone* in *France*, *Ravenna*, and *Rome* in *Italy*. The third and fourth came from *Candy*: the fift was ſent out of *Italy* among other ſeedes: the ſixt came from *Hungary*, and other parts of *Germany*: the ſeventh and laſt from *Spaine* and *Italy*.

The Time.

They all flower about *Iuly*, yet ſome a moneth ſooner, and the ſeede will be ripe within a moneth after the flowers are paſt.

The Names.

This hath no Greeke appellation more then what may be taken from the Latine, for being of later invention, or uſe at the leaſt, it hath obtained divers Latine names, as *Scrophularia major*, becauſe it is availeable *ad Scrophulas*, and *major* to diſtinguiſh it from the leſſer, (which moſt writers call *Chelidonium minus*, with what judgement you ſhall heare anon) *Millemorbia*, *Ficaria*, *Ferraria* and *Caſtrangula*, as well from the forme of the rootes, as from the many effects, the former ages more then ours did put it too, and did finde it availeable; the other ſorts although they want thoſe knobbes in the rootes, yet for the other likeneſſe have the ſame name impoſed on them, *Fuſchius Cordus*, and *Dodonæus* did take it to be *Galeopſis* of *Dioſcorides*, but *Dodonæus* in his laſt Edition, finding his former errour amendeth it ſaying, that this wanteth the ſtrong ſent that *Galeopſis* hath, beſides other things. Some alſo tooke it to be *Chryſippea* of *Pliny*, which he ſaith, uſed with Figges helpeth the knots or kernells in the fleſh: the *Italians* call it *Scrofolaria*, the *French Grande Scrofulaire*, the *Germanes Braunwurtz* and *Groſſ Feigwurtz*, the *Dutch Groot Speenkruijt*, and we in *Engliſh* great Figgewort, and great Pilewort, and of ſome great Kernell wort; the firſt is called *Scrophularia*, and *major* of moſt writers: onely *Tragus* not allowing of the name *Scrophularia*, more to be given unto this plant then unto the *Saxifraga alba*, calleth it *Ocimaſtrum alterum*, and *Geſner in hortis*, calleth it *Clymenum mas*, and as I ſayd before *Galeopſis* of *Fuſchius*, *Cordus*, and *Dodonæus*, in his *Dutch* Herball; the other of the great kind hath not beene mentioned by any before. The ſecond is called *Ruta Canina* of *Lobel*, *Cluſius* and others, from them of Mompelier, but hath little or no likeneſſe to any Rue; and is called by many alſo *Scrophularia major abſque tuberculis*. *Matthiolus* ſetteth it forth for *Sideritis tertia Dioſcoridis*, as *Camerarius* and *Bauhinus* ſay, although not well expreſſed; but *Lacuna*, *Lonicerus*, *Dalechampius* and ſome others would make it the *Sideritis altera* of *Dioſcorides*, and *Dodonæus* in his *Dutch* Herball (which *Cluſius* tranſlated into *French*) *Galeopſis tertia*, *Ceſalpinus* calleth it *Scrophulariæ ſimilis planta major*, *Sideritis ſecunda Dioſcoridis*. *Bauhinus* calleth it *Scrophularia Ruta Canina dicta vulgaris*: the third is the firſt *Scrophularia Cretica* of *Cluſius*, which as he ſaith is very like unto the *Ruta Canina*, and therefore *Bauhinus* calleth it, *Scrophularia folijs filicis modo laciniatis*, *vel Ruta Canina latifolia*: the later *Gerard* calleth *Scrophularia Indica* but how truly let others judge. The fourth is called *Scrophularia peregrina* by *Camerarius*, who thinketh it to bee the *Galeopſis* of *Anguillara*, and is the ſecond *Scrophularia Cretica* of *Cluſius*, and by *Bauhinus* called *Scrophularia folio Urticæ*: the fift hath the name in the title whereby wee received it: the ſixt is called *Scrophularia flore luteo*, by *Bauhinus*; *Fabius Columna* calleth it *Scrophularia montana maxima*, and thinketh it alſo to be the *Lamium Pannonicum ſecundum ſive exoticum* of *Cluſius*, but ſaith *Bauhinus* there is ſome difference, and I doe verily thinke them two ſeverall plants. The ſeventh is called by *Bauhinus* *Scrophularia folijs laciniatis*, and ſaith it was ſent him by the name of *Scrophularia Hiſpanica*, but we received it under the name of *Scrophularia Indica*: which whether it be naturall of the *Indies* or of *Spaine*, wee cannot tell, for many things are ſo miſconſtered: the laſt came to mee among other ſeedes by the ſame name is in the title, and by me with many other of our rareſt ſorts of ſeedes ſent unto Dr. *More* while hee lived at *Padoa*, and by him imparted to *Alpinus*, who mentioneth it as received from him.

The Vertues.

It is very effectuall to diſſolve clotted or congealed blood within the body, which happeneth by any wound or by any bruiſe or fall, both to be taken inwardly by the decoction of the herbe, and by applying the herbe bruiſed upon the hurt place outwardly: the ſame alſo is no leſſe effectuall for the Kings Evill, or any other knots, kernels, bunches or wennes growing in the fleſh whereſoever: it is of ſingular good uſe to bee applyed for the hemorrhoides or piles, when they grow painefull and fall downe, and for other ſuch knobbes or kernells as ſometimes grow in and about the Fundament. An oyntment made hereof in this manner may bee uſed at all times, when the freſh herbe is not to be had. Waſh the rootes cleane, bruiſe them and put them into a pot with freſh Butter well mixed together, and let them ſo ſtand for fifteene dayes cloſe covered in ſome moyſt or mooriſh place, which afterwards ſet upon a gentle fire to boyle eaſily for a little ſpace, which then being ſtrained forth let it be kept in a pot covered to uſe when occaſion requireth: with the roots and leaves likewiſe bruiſed and boyled in *axungia* or oyle and wax, is made the like oyntment, exceeding good to heale all ſorts of Scabbes and Lepry alſo. The diſtilled water of the whole plant rootes and all, is uſed for the ſame purpoſes, eyther to take inwardly or to apply outwardly by bathings, and ſerveth well alſo for fowle Vlcers that are hollow or corroding, to

ſtay

ſtay the malignitie and dry up the ſuperfluous virulent moyſture of them; the ſame alſo taketh away all redneſſe ſpots and freckles in the face, as alſo the ſcurfe, or any foule deformitie therein that is inveterate, and the Leproſie likewiſe.

CHAP. LXVIII.

Betonica aquatica. Water Betony.

BEcauſe this herbe is ſo like unto the former Figwort, that many as I ſayd are miſtaken therein, and that it is called *Scrophularia aquatica* alſo by ſome; I thought it not amiſſe to joyne it next thereunto, as well as for the ſame properties that this ſerveth, eſpecially for Vlcers and ſores.

1. *Betonica aquatica major.* The greater Water Betony.

The greater Water Botony riſeth up uſually higher then the Figwort, with ſquare hard greeniſh ſtalkes, and ſometimes browne, ſet with ſuch like broad darke greene leaves, as the Figwort hath, and dented about the edges, but with rounder notches whereby it may if heedefully obſerved be knowne from it, and wherein it ſomewhat reſembleth the leaves of the Wood Betony, but much larger two for the moſt part ſet at a joynt; the flowers are many ſet at the toppes of the ſtalkes and branches, being round bellyed and open at the brimmes, and devided into two parts, the uppermoſt being like a hood, and the loweſt like a lip hanging downe, of a darke red colour, which paſſing away there come in their places round heads with ſmall points in the ends, wherein lyeth ſmall and browniſh ſeede: the roote is a thicke buſh of ſtrings and threds growing from a head.

Betonica Aquatica.
Water Betony.

2. *Betonica aquatica minor.* The leſſer water Betony.

The leſſer Water Betony is in all things like the former, but lower and leſſer by three parts, for the ſtalkes are ſquare and greene; the leaves are round almoſt, but yet pointed, of the ſame darke greene colour, the flowers are of a ſad red, or purple colour, and the rootes threddy, ſo that the ſmalneſſe onely maketh the greateſt difference.

The Place.

The firſt groweth with us by ditch ſides, by brookes and other water courſes, generally throughout the land, and is ſeldome found any thing farre from the waters ſides: the ſecond alſo in wet and mooriſh grounds about *Baſil* as *Bauhinus* ſaith, and in other places of *Germany*, and will well abide in dryer grounds, as *Lobel* found in the garden of Dr. *Penny* at *London*, and Dr. *Mutonus* at *Tornay*.

The Time.

Theſe flower about *Iuly*, and their ſeede is ripe in *Auguſt*.

The Names.

It is called *Betonica aquatica* and *aquatilis* by *Dodonæus*, *Lobel*, *Lugdunenſis*, *Tabermontanus*, *Gerard* and *Turner*, who yet tooke it to be *Clymenon*, as *Geſner* alſo did, calling this *Clymenon fœmina*, as he did the common *Scrophularia*, as I ſayd before *Clymenon mas*, and therefore calleth this alſo *Scrophulariæ majoris altera ſpecies*. *Dodonæus* in *Dutch* maketh it his ſecond *Galeopſis*, and *Tragus* his greater *Ocimaſtrum*. *Lobel* ſaith that ſome called it *Seſamoides*, and ſome *Terpentaria*; *Thalius* calleth it *Scrophularia major aquatica*, and ſo doth *Bauhinus*, the other is called by *Camerarius* in his *Matthiolus*, and Epitome of *Matthiolus* *Scrophularia fœmina*, and ſaith the *Germanes* call it *Wiſſ Nachtſchat*, that is, white Nightſhade. *Lobel* in his obſervations pag. 288. calleth it *Betonicæ aquaticæ Septentrionalium ſpecies minor*. The *Dutch* doe call it *Beekſcuymeruyt* and S. *Anteunis cruyt*, we in *Engliſh* call it Water Betony moſt uſually, but ſome Brownewort, from the *Germane Brauwurtz*, as it is likely, which as I ſayd before is the greater *Scrophularia*, the likeneſſe of the plants cauſing ſuch interpoſition of names, and ſome alſo Biſhop leaves.

The Vertues.

Both ſorts of Water Betony are alike effectuall for all old and filthy Vlcers, being of a clenſing quality, if the leaves be but bruiſed and layd thereon; but is much more effectuall if the juice of the leaves bee boyled with a little honey and tents dipped therein, & the ſores dreſſed therewith, as alſo for bruiſes or hurts whether inward or outward: the diſtilled water of the leaves is uſed for the ſame purpoſes, as alſo to bathe the face or hands that are diſcoloured by the Sunne, or hath any ſpots or blemiſhes thereon; as alſo for any redneſſe or high colour that commeth accidentally by being in the Sunne.

CHAP. LXIX.

Betonica. Wood Betony.

OF Betony wee have foure or five ſorts, differing eyther in the leafe or flower, or ſpiked heads of flowers one from another, as ſhall be ſhewed you.

1. *Betonica vulgaris flore purpureo.* Common Wood Betony.

The ordinary or common Betony, which becauſe it is frequent in woods, is therefore generally called Wood Betony, hath many leaves riſing from the roote, which are ſomewhat broad and round at the ends, roundly dented about the edges, ſtanding upon long footeſtalkes; from among which riſe up ſmall ſquare ſlender, but yet upright hairy ſtalkes, with ſome leaves thereon, two a peece at the joynts, ſmaller then the lower, whereon are ſet ſeverall ſpiked heads of flowers, like unto thoſe of Lavender, but thicker and ſhorter for the moſt part, and of a reddiſh or purple colour, ſpotted with ſome white ſpots, both in the lower & upper part on the inſide yet there is obſerved a different ſort from this, whoſe head is ſhorter & flowreth uſually earlier then the former: the ſeede followeth conteined within the husks that hold the flowers, which are blackiſh, ſomewhat long and uneven: the rootes are many white threddy ſtrings, like unto thoſe of Plantaine; the ſtalke periſheth, but the rootes with ſome leaves thereon abide all the winter; the whole plant is ſomewhat ſmall and of a reſinous ſavour.

Præcujor.

2. *Betonica flore albo.* Wood Betony with white flowers.

This Betony differeth in no one thing from the former, ſo much as in the colour of the flowers which are wholly white without any ſpots at all in them, onely the leaves may ſeeme to be a little greener, and the ſpiked head of flowers ſomewhat ſmaller then the other.

3. *Betonica minima Alpina Helvetica.* Small Mountaine Betony.

This ſmall Betony likewiſe differeth not from the former, neither in forme or colour, but in the ſmalneſſe of leaves, ſtalkes and flowers.

4. *Betonica Danica.* Broad leafed Betony.

This great Betony likewiſe differeth not from the ordinary, in any other thing then in the largeneſſe of the leaves, being twice, and in ſome at ſometimes three or foure times as large as the common ſort, and of a ſtrong almoſt ſtinking ſmell; and in the ſtalke which is ſtronger growing higher, and the heads of purple flowers greater alſo.

5. *Betonica Alopecuros montana dicta.* Foxtaile Betony.

This herbe that I here bring to your conſideration, is accounted by *Bauhinus* as a kind of Betony, or referred thereunto for the likeneſſe of the leaves, whom I alſo herein follow, and place it with them; it hath a blackiſh tuberous roote, with ſome fibres thereat; from whence riſe up divers ſlender round ſtalkes, about a cubit high,

1. *Betonica vulgaris flore purpureo.*
Common Wood Betony.

3. *Betonica minima Alpina Helvetica.*
Small Mountaine Betony.

having

4. *Betonica major Danica.*
Broad leafed Betony.

5. *Betonica Alopecuro montana dicta.*
Fox taile Betony.

having at the bottome of them ſome ſmall long and narrow leaves, like threds or peeces as it were torne off from the rinde of the lower part of the ſtalke and ſharpe pointed, ſome greene and ſome browne: the reſt of the ſtalkes are naked unto the middle, which from thence to the toppes at farre diſtances one from another, have at every joynt two broader, rounder, and ſhorter leaves then Betony, the middle ribbe being blackiſh, and dented about the edges: above the two uppermoſt leaves come forth a ſoft round ſpiked ſhort head made of a number of white haires, ſomewhat reſembling a white Fox taile, whereof it tooke the name.

The Place.

The firſt two ſorts are frequent in woods and copſes, and other ſuch like ſhadowie places throughout the land, but that with the white flower is more uſually found in the ſtiffe clay grounds, then in any other mould, and in the woods by *Brumley* in *Kent*; the third grow on the *Alpes* of *Helvetia* or *Swiſſerland*: the fourth was brought from *Denmarke* by Dr. *Lobel*, when he went thither with the Lord *Edward Zouche* Ambaſſadour from the Queene *Elizabeth* of famous memory, in the yeare 1592. The laſt as *Lugdunenſis* ſaith, groweth in the moyſt vallies that are ſhadowed with trees of the high hills.

The Time.

They flower in *July*, and the ſeede ripeneth quickly after.

The Names.

It is called in Greeke κέστρον *Ceſtron*, *a remediorum copia & varietate*, yet ſome take it *a floris ſpicata & mucronata acutie verruculum preferente*, and ψυχότροφον *Pſycotrophon*, *quod in frigidis locis inveniatur*: the word *Ceſtron* hath divers interpretations in Greeke as in *Suidas* for a kind of dart, in *Sophocles* for a pricke or pointed thing; others underſtand hereby bookes conteining much variety of matter, and *Pliny* ſpeaking of graving, ſaith anciently there were two wayes, the one in wax, the other in *Ebore Ceſtro, id eſt, viriculo*, ſet downe for *veruculum*, which expreſſeth both in Greeke and Latine the ſharpe pointed toole wherewith they did grave in Ivory. It is called in Latine *Betonica*, and *Vetonica*, *ab inventoribus Vetonibus Hiſpaniæ populis* as *Pliny* ſaith; but *Galen* ſeemeth in his fift booke *de ſanitate tuenda*, to make *Betonica* and *Ceſtron* to be two herbes, in theſe words tranſlated, *Conjicitur autem in vinum petroſelinum, atque id ſolum articularibus ſatisfaciat; ijs vero qui calculo laborant, aliquid Betonicæ & Ceſtri quod in Gallijs naſcitur, vocent autem eam herbam Sarxiphagon*: *Ætius* alſo in his fourth booke and 30. Chap. reciting this place of *Galen* ſaith, *Ex quibus colligitur non ſolum Latinorum Betonicam, ſed etiam Gallorum Sarxiphagon, Ceſtron nominatum fuiſſe*. *Paulus Ægineta* in his ſeventh Booke doth plainely ſet downe two ſorts of Betony, the one with ſlender branches like unto Pennyroyall, but ſmaller, and almoſt without taſte, growing eſpecially in ſtony places (& as I ſaid before in the Chapter of *Lamiũ* is taken by *Quadramius* to be *Lamium Scutellaria dictum*) which is uſed in thoſe medecines that are for the reines: the other is the Romans Betony which *Dioſcorides* calleth *Ceſtron*, and others *Pſychotrophon* becauſe it joyeth in cold places, and hath no likeneſſe to the for-

mer but in the qualities and vertues, thus saith *Ægineta*. It is called by the *Arabians Chastura*, by the *Italians Betonica*, but as *Pliny* saith (*lib.25.cap.8.* speaking of his times) *Serratula*, by the *French Betoine*, and *Betoosne*, by the *Germanes Braun Betonick*, by the *Dutch* and us Betony. There needeth no further declaration or explanation of these unto you, seeing all Authors almost agree in the name. The third and fourth by their title and place are expressed whereupon they tooke their names: the last *Lugdunensis* calleth *Alopecurus montana*, which hath Betony like leaves, and therefore *Bauhinus* as is before said referred it thereunto. One thing more I would advertise you that *Vetonica* and *Betonica* are diversly taken in divers Authors for *Vetonica*, although it be set downe in some Authors for *Betonica*, yet more properly and usually it is understood to bee the *Caryophyllus*, our Gilliflower, and then it is denominated *Vetonica altilis*.

The Vertues.

Betonie is hot and dry, almost in the second degree: it is saith *Pliny ante cunctas Laudatissima*, and so have others also set it forth, with admirable (and yet not undeserved) praises: *Antonius Musa*, the Emperour *Augustus* his Physition, who who wrote a peculiar booke hereof, saith of it, that it preserveth the lives and bodies of men, free from the danger of diseases, and from witchcrafts also; but it is found by dayly experience, as *Dioscorides* formerly wrote thereof, to be good for innumerable diseases, as *Matthiolus* termeth it, for it helpeth those that either loath ot cannot digest their meate, those that have weake stomackes, or have sower belchings, or continuall risings in their stomacke, if they use it familiarly, either greene or dry, either the herbe, the roote, or the flowers, in broth drunke, or meate, made into conserve, syrupe, electuary, water, or powder, as every one may best frame themselves unto, or as the time or season requireth, taken any of the foresayd wayes: it helpeth the jaundise, falling sickenesse, the palsie, convulsions or shrinking of the sinewes, the goute, and those that are enclining to dropsies, as also those that have continuall paines in their heads, yea although it turne to frensie: it is no lesse availeable the powder mixed with pure honey, for all sorts, of coughes or colds, wheesing and shortnesse of breath, distillations of thinne rheume upon the lungs, which causeth consumptions, the decoction made with Mede and a little Pennyroyall added thereunto, is good for those that are troubled with putride agues, whether *quotidiane*, *tertian*, or *quartine*, that rise from the stomack; and to draw down and evacuate the blood and humors, that by falling into the eyes, do hinder the sight: the decoction thereof made in wine & taken, killeth the wormes in the belly; is good to open the obstructions, both of the liver & spleene, & for stitches or other paines in the sides or back, the torments also & griping paines of the bowels, and the wind Collick, and with honey helpeth to purge the belly: the same also helpeth to bring down womens courses, and is of especiall use for those that are troubled, with the falling downe of paines of the mother, and to cause an easie and speedy delivery for those in travaile of childbirth: it helpeth also to breake and expell the stone, either in the Kidnies or bladder; the decoction with wine gargled easeth the toothach: it is commended against the sting or biting of venemous Serpents, and mad dogs, both used inwardly and applyed outwardly, also to the hurt place: it is sayd also to hinder drunkennesse, being taken before hand, and quickely to expell it afterwards: a dramme of the powder of Betonie taken with a little hony, in some Vinegar, doth wonderfully refresh those that are overwearied by travaile: it stayeth bleedings at the mouth or nose, as also those that spit or pisse blood: it helpeth those that are burSten and have a rupture, and is good for those that are bruised by any fall or otherwise: the greene herbe bruised, or the juyce applyed, to any inward hurt, or outward greene wound, in the head or body, will quickely heale it and close it up, as also any veines or sinewes that are cut, and will also draw forth any broken bone, or any splinter, thorne, or such other thing, gotten into the flesh: it is no lesse profitable for old filthy sores, and ulcers, yea though they be fistulous and hollow; but some doe advise to put a little salt thereto for this purpose: being applyed with a little Hogges Lard, it helpeth a Plague sore, and other biles, and pushes: the fumes of the decoction while it is warme, received by a funnell into the eares, easeth the paines of them, estroyeth the wormes, and cureth the running sores in them; the juyce dropped into them, doth the same likewise: the roote of Betony is found to be of much differing quality from the leaves and flowers, as being much displeasing both to the taste and stomacke, procuring loathing, vomitings, and belchings; whereas the leaves and flowers, by their sweete and spicie taste, are comfortable both in meate and medicine.

CHAP. LXX.

Chelidonium. Celandine.

FOrmerly there were two sorts of Celandine generally knowne, as *Dioscorides* and others make mention, which differ in outward face, very much one from another, whereof I entend to entreate in this Chapter, but unto them I must adjoyne some other sorts of the greater, which are of later invention.

1. *Chelidonium majus vulgare.* Common great Celandine.

Common Celandine hath divers tender, round whitish greene stalkes, with greater joynts than ordinary in other herbes, as it were knees, very brittle and easie to breake, from whence grow branches, with large tender long leaves, much divided into many parts, and each of them cut in on the edges, set at the joynts upon both sides of the branches, of a darke blewish greene colour on the upperside, like unto Colombines, and more pale blewish greene underneath, full of a yellow sappe or milke, when any part is broken, of a bitter taste and strong sent: at the toppes of the branches which are much divided, grow gold yellow flowers, of foure leaves a peece, after which come small long pods, with blackish seede therein: the roote is somewhat great at the head, shooting forth divers other long rootes, and small fibres reddish on the outside, and yellow within full of a yellow sappe therein.

2. *Chelidonium majus laciniatum.* Iagged Celandine.

This other great Celandine groweth in all things like the former, but that the leaves are thinner, and the division slenderer, and more cut in on the edges: the flowers likewise are of the same gold yellow colour, and consisting of foure leaves, somewhat larger than the other, and are each of them cut in on the edges, as the greene

leaves

leaves are: this as the other by the ſhedding of the ſeede, riſech againe before winter, and ſo abideth flowring the next ſpring, and ſeeding in ſommer.

3. *Chelidonium maximum Canadenſe* ἀκαυλον.
Great *Celandine* of *Canada.*

This ſtrange Celandine hath a fleſhie roote, full of a yellow juyce, ſmelling ſtrong like the ordinary, from whence riſe onely three large blewiſh greene leaves, cut in after the manner of Vine leaves, without any foote ſtalke under them, or with very ſhort ones, from among which riſe a ſhort reddiſh foote ſtalke, with a white flower on the toppe of it like unto the flower of Sowbread.

4. *Chelidonium minus.* Small Celandine or Pilewort.

Although there is no affinity in the forme hereof unto the former, as I before ſayd, yet becauſe it generally beareth the name of the leſſer Celandine, and that it is of an healing quality, eſpecially for the piles, I thought good to joyne it with the other for this worke, which elſe might be ſevered. This ſmall Celandine doth ſpread many round pale greene leaves, ſet on weake and trayling branches, which lye upon the ground, and are fat, ſmooth, and ſomewhat ſhining, and in ſome places, though ſeldome, marked with blacke ſpots, each ſtanding on a long foote ſtalke; among which riſe ſmall yellow flowers, conſiſting of 9. or 10. ſmall narrow leaves, upon ſlender foote ſtalkes, very like unto a Crowfoote, whereunto the ſeede alſo is not unlike, being many ſmall ones ſet together upon a head: the roote is made of many ſmall kernels, like graine of corne, ſome twice as long as others, of a whitiſh colour with ſome fibres at the end of them.

There is another ſort hereof, which hath as it were double flowers, conſiſting of two rowes of leaves, in all other things not differing from the former, which *Camerarius in horto,* onely mentioneth.

1. *Chelidonium majus vulgare.*
Common great Celandine.

Flore duplici.

2. *Chelidonium majus laciniatum.*
Iagged Celandine.

3. *Chelidonium minus.*
Small Celandine or Pilewort.

4. *Chelidonia rotundifolia major.* A greater ſmall Celandine.

This greater ſort of the ſmall Celandine, hath a fibrous roote, whereunto grow ſmall round knobs: the leaves are round thicke and ſmoth, growing almoſt as large as *Aſarum*, or *Aſarabacca*, ſometimes a little waved about the edges, each ſtanding upon a longer foote ſtalke than the former, yet lying upon the ground: the flowers that ſtand ſeverally as the others doe, upon longer foote ſtalkes, are of a pale yellow colour, and larger than they, conſiſting but of five or ſixe leaves, cut in at the ends, unto the middle of them, and having ſome reddiſh threds in the middle of the flowers.

The Place.

The firſt groweth in many places by old wall ſides, and by the hedges and way ſides in untilled places, and being once planted in a garden, eſpecially in ſome ſhady place, it will ſtill be found therein, the ſecond is not knowne where it is naturall, but is received into gardens for the varietie: the ſmall ſort groweth for the moſt part in the moyſt corners of fields, and places that are neere water ſides, yet will abide in dryer groundes, ſo as they be a little ſhadowed; the third in *Canada* as the title ſheweth: the laſt groweth in the wet grounds about *Mompelier*.

The Time.

The two firſt ſorts flower all the Sommer long, and the ſeede ripeneth in the meane time: the other flower betimes about *March*, or *Aprill*, and is quite gone in *May*, ſo at it cannot be found untill it ſpring againe; that of *Canada* flowred late but gave no ſeede.

The Names.

The firſt and greater is called in Greeke χελιδόνιον τὸ μεγὰ, in Latine *Chelidonium majus*, and *Hirundinaria major*: the leſſer is called χελιδόνιον τὸ μικρὸν, and in Latine *Chelidonium minus*, and *Hirundinaria minor*: ſome call them *Chelidonia major & minor*, and tooke the name as *Dioſcorides* ſaith, becauſe it ſpringeth when Swallowes come in; and withereth at their going away (which is true in neither, the greater whereof *Dioſcorides* chiefely ſpeaketh, being greene both winter and ſommer, and the leſſer ſpringing before Swallowes come in, and is gone and withered long before their departure,) *Dioſcorides* likewiſe and *Pliny* alſo, ſay it tooke that name from Swallowes that cured their young ones eyes, that were hurt, with bringing this herbe, and putting it to them: but *Ariſtotle*, and *Celſus* from him, doe ſhew that the young ones of Partridges, Doves, Swallowes, &c. will recover their ſight (being hurt) of themſelves in time, without any thing applyed unto them, and therefore *Celſus* accounteth this ſaying but a fable. The *Chimiſts* in former times, in miſtaking the Greeke name, called the greater kinde *Cæli donuim*; and thereupon did highly extoll the Quinteſſence drawne from it, not onely to expell many diſeaſes, but for many their idle and fantaſticke tranſmutations: the leſſer ſort beſide the former names, is called *Ficaria & Scrophularia minor* of *Brunfelſius*, of *Fuſchius Malacociſſos minor*, whom *Matthiolus* taxeth therefore, *Guilandinus* and *Cordus* tooke it to be *Amellus Virgilii*, as we ſhewed you in the Chapter of *Amellus* or *Aſter*. *Sylvaticus* calleth it *Teſticulus ſacerdotis*, and is likely to be the *Ranunculus latifolius* of *Lugdunenſis*. *Bauhinus* calleth it *Chelidonia rotundifolia*: it is thought alſo to be the *Strumea* of *Pliny*, whereof he ſpeaketh among the *Ranunculi*: many doe make doubt whether this herbe be the *Chelidonium minus* of *Dioſcorides* and *Galen*, becauſe it hath not any acrimonie or ſharpeneſſe therein, as they ſay is in theirs: but yet all writers doe agree, that howſoever it hath not any acrimony, it is in forme and all other properties the ſame. It is as I ſayd called *Ficaria* and *Scrophularia minor*, *a ſignatura*, from the likeneſſe of the rootes unto thoſe *Strumæ* called *Scrophulæ*, which appeare in *ano*, *& ad tonſillas*, and therefore as in many other the like, held powerfull to cure them; the greater is called of the *Italians Celidonia maggiore*, of the *Spaniards yerva de las golondrinhas*, and *Celidrenha*: of the *French Chelidoine Felongue* and *Eſclaire*: of the *Germanes Groſs Scholwurtz* and *Goldwurtz*, and *Schwalbenkraut*: of the *Dutch Gonte wortel en groot gouwe*: and we in *Engliſh* great Celendine, and of ſome Swallow-wort, and Tetterwort. The leſſer is called by the *Arabians Memicen*, by the *Italians Favagello* and *Favoſcello*: by the *French Coullions de preſtre*, or *petite Eſclaire*: by the *Germanes Meinkraut* and *Klein Feigwartzen*: of the *Dutch Cleyne Gouwe* or *ſpeene cruiit*: and we in *Engliſh* ſmall Celandine, Pilewort, and of ſome Figge-wort.

The Vertues.

The greater Celandine is hot and dry in the third degree, and of a clenſing facultie; It openeth the obſtructions of the Liver and Gall, and thereby helpeth the yellow Iaundies, the herbe or the rootes being boyled in white wine with a few Anneſeedes and drunke: *Matthiolus* ſaith that if the greene herbe be worne in their ſhooes that have the yellow Iandies, ſo as their bare feete may tread thereon, it will helpe them of it; the ſame alſo taken in the ſame manner, helpeth thoſe that are inclining to the dropſie, or have it confirmed in them by often uſing it, as alſo for thoſe that are troubled with the itch, or have old ſores in their Legs, or other parts of their bodies: the juice thereof taken faſting, is held to bee of ſingular good uſe againſt the Plague or Peſtilence, and ſo is the diſtilled water alſo with a little Sugar, but eſpecially if a little good Treackle bee mixed therewith, and they upon the taking layd downe to ſweate a little: the juice dropped into the eyes doth clenſe the eyes from filmes and clouds that darken them: but becauſe it is ſomewhat ſharpe, the hardned juice relented with a little breaſt milke will well allay it: it is to good purpoſe uſed in old filthy or corroding and creeping Vlcers whereſoever, to ſtay their malignitie of fretting and running, and to cauſe them to heale the more ſpeedily: the juice often applyed to tetters, ringwormes or other ſuch like ſpreading Cancers, will quickly kill their ſharpeneſſe and heale them alſo: the ſame rubbed often upon warts will take them away: the herbe with the rootes bruiſed, and heated with oyle of Camomill, and applyed to the Navill, taketh away both the griping paine in the belly and bowells, as all the paines of the mother, and applyed to womens breaſts that have their courſes in two great aboundance ſtayeth them; the juice or the decoction of the herbe gargled betweene the teeth that ake, taketh away the paine, and the powder of the dryed roote, layd upon an aking, hollow, or looſe tooth, will as they ſay cauſe it quickly to fall out: the juice mixed with ſome powder of brimſtone is not onely good to annoint thoſe places that are troubled with the itch, but taketh away all the diſcolourings of the skinne whatſoever, be they ſpots or markes of bruiſes, ſtripes or wounds, the Morphew alſo, ſunburning or any the like; and if it chance that in a tender body it cauſe any itching or inflammation, by bathing the place with a little Vinegar it is ſoone helped: the leſſer Celandine, becauſe it hath not that acrimony with us, that it ſeemeth it hath in Greece, where *Dioſcorides* lived, cannot have thoſe properties, they aſcribe unto their *Chelidonium minus*, which is, the juice taken

taken from the rootes, and put up into the nose purgeth the head, and a decoction thereof with a little honey put to it and gargled in the mouth, doth the same effectually, and doth purge and cleanse the brest of flegme or any other tough humors that doe offend: it also helpeth a running itch, and those nailes of the fingers and toes that grow deformed, and scabbed: thus farre *Dioscorides* and *Galen*, but it is certaine by good experience, that the decoction of the leaves and rootes doth wonderfully helpe the piles or hemorrhoides, as also kernels by the eares and throate, called the Kings Evill, or any other hard wennes or tumors.

CHAP. LXXI.

Dentaria. Toothed Violets, or Coralworts.

THere be divers sorts of these toothed Violets, differing one from another, eyther in roote or leafe or both, as you shall presently understand.

1. *Dentaria bulbifera.* Bulbe bearing toothed Violets.

This toothed Violet shooteth forth one or two winged leaves, upon long browniſh footestalkes, which in their rising up out of the ground, are as it were doubled or foulded downewards, and then open themselves into seaven leaves most usually, and sometimes but five, each whereof is somewhat long, dented about the edges, and pointed, of a sad greene colour, and set on both sides of the middle ribbe one against another: the stalke that beareth flowers riseth up in the same manner with the leaves, and is bare or naked of leaves unto the middle thereof, where it shooteth forth a leafe, and so one or two more up higher, each consisting but of five leaves, and sometimes but of three, having also the uppermost single, at each whereof commeth forth a small round Bulbe, cloven, or as it were divided into some parts or cloves, of a sad purpliſh greene colour, which being ripe and put into the ground, will grow to be a roote, and beare leaves like as the Bulbes of a red bulbed Lillie; about which at the very toppe stand foure or five flowers in long huskes upon short footestalkes, opening into foure leaves, of a purpliſh colour, very like unto the flowers of Stocke Gilloflowers, or Dames Violets; after which come small long hornes or cods pointed at the ends, wherein lye such like seede, as are in the cods of Dames Violets, which will as soone as it is ripe, breake the podde and fall out: the roote is very white smooth and shining, made of divers small round knobbes set together not growing downewards, but lying along, and encreasing under the upper cruſt of the ground, having very few fibres thereat; the taste both of leafe and roote is somewhat bitter, hot and sharpe like Raddish, as all the rest of these sorts are.

2. *Dentaria Pentaphyllos.* Cinquefoile Corrallwort.

The first sort of Cinquefoile Corrallwort or toothed Violet, hath likewise one or two leaves rising from the roote, upon long footestalkes, consisting of five parts or leaves, each of them somewhat like the former, and dented about the edges, but they are longer, rougher and harder in feeling, and more closely set together, rising for the most part from one joynt, like as the Cinquefoiles doe: upon the stalkes also are some such like leaves, set one above another, at the toppe foure or five such like flowers, but somewhat larger, of a purpliſh colour, somewhat deeper then the former which turne into such like pods, with the like seedes in them, and hath no bulbes on the stalke: the roote hereof is greater, made as it were into joynts not so white as the former, and with longer fibres issuing from betweene the joynts.

3. *Dentaria pentaphyllos altera.* Another Cinquefoile Corallwort.

The roote of this Corallwort is very like the first, consisting of many round cleare white knobs but more in number, set together by peeces, with divers long fibres growing out of it, which shooteth forth a smaller and lower stalke then the former, being not above a foote high, with some leaves set thereon, as also there is some of those very like the last, but narrower; more smooth and gentle, of a paler greene colour also: the flowers that stand at the toppe like unto the others, are of a purpliſh colour, after which come the like pods with seede in them, as the rest.

4. *Dentaria triphyllos.* Trefoile Corallwort.

This Corrallwort sendeth forth two or three leaves consisting of three parts onely, each whereof are rounder and somewhat larger then the other sorts, dented about the edges, and of a darke greene colour: about the middle of the stalke that beareth flowers, the lower part being bare or naked of leaves, stand three leaves each of them standing by it selfe upon a stalke, consisting of three leaves a peece, nine in all, which are narrower and longer then those below, and longer pointed: the flowers are of a pale greeniſh colour, hanging downe their heads, after which come such like seede, in somewhat thicker pods: the roote is composed of somewhat longer peeces, set together somewhat like unto the lesser Lungewort, which will turne blackiſh when it is a little dry.

5. *Dentaria Heptaphyllos.* Setfoile Corallwort.

The Setfoile Corallwort riseth likewise with two or three leaves from the roote, set upon long footestalkes like unto the first sort, consisting of seven leaves set all along a middle ribbe in the same manner, and sometime but of five leaves, of a paler greene colour on the upper side, and more grayiſh underneath; the stalke hath some such like leaves thereon, but no bulbes, and the flowers at the tops are in forme like the other, but larger, and in some white, and in others purpliſh: the cods and seedes are like the rest, but the roote hereof is not so much parted as the former, but more thicke and tuberous.

6. *Dentaria anguſtifolia bulbifera.* Bulbed narrow leafed Corallwort.

This Corallwort riseth up with a stalke or two, bearing long and narrow leaves dented about the edges, of sad greene colour, and pointed at the ends somewhat like the leaves of *Ptarmica ſylveſtris*, called wilde Pelletory every one standing singly by it selfe, and at the joynts therewith, come forth such like scaly balebs as are in the first sort, but thicker and of a darke purpliſh colour, but none among the flowers which grow many together, of the

1. *Dentaria Bulbifera.*
Bulbed Corallwort.

2. *Dentaria pentaphyllos & triphyllos.*
Cinquefoile and trefoile Corallwort.

5. *Dentaria Heptaphyllos.*
Setfoile Corallwort.

6. *Dentaria angustifolia Bulbifera.*
Bulbed narrowleafed Corallwort.

the same fashion with the other, that is, of foure leaves a peece, but they are of a whitish colour, after which come long pods with seede like the other: the roote is white and somewhat short, growing aslope as the rest doe, set together with joynts, somewhat closer and more even with some fibres at it.

7. *Alabastrites sive Dentaria minima.*
The least Corallwort.

Although I know that this plant is referred by most unto the *Ranunculi* or Crowfeet & so have I done here before, yet having gained a more perfect figure thereof, and considering the small likenesse it hath with any sort of Crowfoote, and the nearer resemblance of it unto these kindes of plants I have presumed to insert it in this place for the mine sake, and likenesse of the roote, although you have the exact description thereof among the Crowfeete under the name of *Ranunculus nemorosus Moschatella dictus.*

The Place.

The first and the last have beene found in our land; the first at *Mayfield* in *Sussex*, in a wood called Highreede, and in another wood there also called Foxholes, both of them belonging to one Mr. *Stephen Perkhurst* at the writing hereof; the rest in the shadowie woods of *Germany*, *Switzerland* and *Savoy*, *Naples*, *Italy*, and divers other places.

The Time.

They flower about the end of *Aprill*, and beginning or middle of *May*, and are withered and gone before *July* for the most part, the rootes abiding safe under ground.

The Names.

Neither *Dioscorides* nor *Pliny*, nor any other of the ancient writers, as divers have supposed have made any mention of these plants, but being found out by later searchers are called diversly; some from the forme and colour of the rootes, calling them *Dentaria*, *Dentillaria*, *Coralloides*, and *Alablastrites* as *Lobel*, and *Dentaria Coralloide radice*, as a difference from other *Dentarias*; and some also thereupon tooke it to be an *Aconitum*, as *Dalechampius* doth in *Lugdunensis*; some both from the roote and the flowers, that are like unto Stocke Gilloflowers, which were anciently comprehended under the name of *Viola*, called it *Viola Dentaria*, as *Dodonæus*, some from the effects and properties as *Cordus lib. 2. plantarum historia cap.* 111. and *Gesner in hortis*, *Samcula alba* and *Saxifraga montana*, and saith that about *Savoy* they call it *Pulmonaria*, but *Columna* taketh it to bee *Ceratia Plinij*, and sheweth plainely that this *Dentaria*, hath all the properties that *Pliny* ascribeth unto his *Ceratia*; for whereas *Pliny* saith, it hath but one leafe, so saith *Columna* this hath but one sometimes, for hee maketh that leafe to bee but one that standeth upon one stalke, howsoever divided into 3. 5. 7. or more parts, as is to bee seene in the Ashtree, Quicken tree, Service and Wallnut, &c. the whole leafe springing forth together and falling away all together, and not one peece after another, as in others that are single, which is a true note how to know a winged leafe from others, as I shewed you formerly in another place. The first and sixt are called *Dentaria bulbifera*, or *baccifera*, because they onely and none of the rest doe beare any bulbes like berries upon their stalkes. They are all generally called *Dentaria*, and most of them from the number of their leaves, called eyther *triphyllos*, *pentaphyllos*, or *heptaphyllos*; but the *triphyllos* is also called by *Lobel Ennerphyllos*, onely the two last differ in some things from all the rest; the sixt being called by *Besler*us, that set forth the great booke of *Hortus Eystetensis*, *Dentaria angustifolia baccifera*, and *Baubinus* thereupon *Dentaria baccifera folijs Ptarmicæ*. *Cordus* in his second booke 111. Chap. of his History of Plants, setteth forth the figure thereof in my minde, but without any bulbes at the leaves, under the name of *Coralloides alia species*. *Gesner* in his *scholia*, at the end of that Chapter saith that the *Dentaria baccifera* was called by some *Consolida Saracenica*, and judgeth it himselfe a kind of *Aconite*: and the last as I have declared in the first division of the Crowfeete.

The Vertues.

The roote of Corallwort is drying, binding and strengthning, yet it helpeth to provoke Vrine, and to expell gravell and the stone, as some doe affirme: it is exceeding good to ease the griping paines of the sides and bowells, and for inward wounds that are made in the breast, longs and bowells, a dram of the powder of the roote taken for many dayes together, in red wine; the same also given to them that are bursten, or have a rupture: it very beneficiall to be drunke in the distilled water of the herbe, called Horsetaile: it stayeth also Laskes and Fluxes that doe not proceede of hot and chollericke humours: the decoction of the herbe is good to bee applyed both to greene wounds, quickly to consolidate them, and for old filthy sores, to dry up their moysture and thereby to cause them heale the sooner.

CHAP. LXXII.

Leucoium. Stocke Gilloflowers

HAvē in my former booke ſhewed you many ſorts of Stocke Gilloflowers, there yet doe remaine divers others which are of leſſe beauty and durabilitie to be entreated of here, as I there promiſed. And becauſe the word *Leucium* in Latine, is referred as well to theſe Stocke Gilloflowers, as to the Wallflowers with this diſtinction of *Luteum* onely. I will alſo diſtinguiſh and ſeparate them, entreating in the next Chapter of thoſe that bare yellow flowers and greene leaves, which is the diſtinction betweene a Wallflower and a Gilloflower, yet I will here give you the figure of the ſingle garden Stocke Gilloflowers.

1. *Leucoium marinum maximum.* The greateſt Sea Stocke Gillowflower.

This Sea Stocke Gilloflower hath divers long thicke whitiſh ſoft leaves, lying upon the ground one within another in a round compaſſe, and are ſtiffer then the other Sea kinds, or the garden kinds formerly ſet forth, jagged alſo or cut in on both ſides evenly, into deepe dents like the knagges of a Bucks horne, which make it ſeeme the more beautifull: thus it doth abide for the firſt yeares growing, but the next yeare it beareth a hoary white ſtalke, three foote high or thereabouts, branching forth into many parts, ſomewhat thicke but weake, ſcarſe able to ſtand upright, whereon grow narrower leaves little or nothing jagged about the edges, and a number of flowers at the toppes one above another, for a great length each of them conſiſting of foure broad pointed leaves a peece, but not altogether ſo ſweete as the other Stocke Gilloflowers, yet ſomewhat larger, and of a pale blewiſh purple colour, almoſt like unto a Dove or Crane colour, after which come ſuch like long pods as the reſt have, with ſeedes lying in a double row in the ſame manner, larger and of a darker colour: the roote is white hard and long, ſpreading into many branches, which abideth not after it hath yeelded ſeede, but periſheth as the other Sea kindes doe.

2. *Leucoium marinum latifolium.* Broad leafed Sea Stocke Gilloflower.

This Sea Stocke Gilloflower hath many hoary leaves lying about the roote, ſhorter and broader then the other Sea kindes, harder alſo in feeling, and as it were rugged, more hairy and finely dented about the edges: from among which riſe up divers round hairy ſtalkes about a foote high, bearing purpliſh blew flowers like the other, and ſmall long pods with browniſh flat ſeede in them.

3. *Leucoium marinum majus.* Great Sea Stocke Gilloflower.

This Greater Sea Stocke Gilloflower hath divers long thicke hoary leaves lying on the ground for the firſt yeare; ſome of them being cut in on the one edge and ſome on both, with but one gaſh and ſome not at all: the ſtalke riſeth up the next yeare about a foote high, or more ſpread itno divers branches, yet all of them weake, and rather bending downewards then ſtanding upright, whereon grow leaves little or nothing parted or cut in, and divers flowers on the toppes of them, of a pale purple colour, drawing neare to the colour of red wine lees; both

Leucoium album vel purpureum.
Ordinary Stocke Gilloflowers white red or purple.

1. *Leucoium marinum maximum.*
The greateſt Sea ſtocke Gilloflower.

this

2. *Leucoium marinum latifolium.*
Broad leafed Sea Stocke Gilloflower.

4. *Leucoium marinum minus.*
The leſſer Sea Stocke Gilloflower.

both this and the next ſmell ſweeter after the Sunne is downe, then in the day time: the cods that follow are long and ſomewhat flat, with reddiſh flat ſeede in them, the roote is divided into many parts.

4. *Leucoium marinum minus.* The leſſer Sea Stock Gilloflower.

This leſſer kinde hath more upright ſtalkes; divided from the bottome into many branches, whereon grow ſoft woolly leaves, ſmaller, narrower, and leſſer jagged than the former: the flowers that ſtand at the toppe of the branches, are ſmaller than the other, but made of foure leaves like the reſt, of a freſh red or crimſon colour, which upon their fading ſeeme to be of a deeper colour, and of a weaker ſent than the other; in their places come long pods wherein are conteined the like red ſeede: the roote is wooddy like the other, and periſheth after ſeede time.

5. *Leucoium marinum minimum.* The ſmalleſt ſea Stockgilloflower.

The leaſt Sea ſtock Gilloflower, hath a browniſh ſquare ſtalke, not above two inches high, ſet with five or ſixe ſmall and ſomewhat long round pointed hoary and hayrie leaves, on both ſides thereof, bearing at the toppe one or two blewiſh flowers; whoſe footeſtalkes are hayrie alſo: the roote is ſmall and threddy, with five or ſixe very ſmall and ſomewhat round pale greene leaves, lying about it, for the firſt yeares increaſe, and flowreth the next.

6. *Leucoium marinum Creticum majus.* The greater *Candy* Stocke Gilloflower.

The greater *Candy* Stocke Gilloflower, hath a round weake ſtalke, branched into many parts, whereon are ſet divers long and narrow leaves ſomewhat thicke and hoary, without any dents or diviſions on the edges, or with very few, and at their toppes many flowers cluſtring together, as it were in tufts, conſiſting of foure leaves a peece, whoſe ends are cut in ſomewhat deeper than others are, making the end ſeeme like unto a heart, as it is uſually expreſſed, ſomewhat reddiſh upon the firſt opening, but of a blewiſh purple when they are full blowen, the bottomes of them being yellow, pointed up like a ſtarre: the cods that follow are about two inches long, and round, conteining within them, ſomewhat long and browne ſeede.

7. *Leucoium Creticum minus.* The leſſer *Candy* Stocke Gilloflower.

This leſſer *Candy* kind is like the former *Candy* ſort in the growing and leaves, but that it is leſſer in both; the flowers alſo are not above halfe ſo great, being fully white at their firſt blowing, and gathering afterwards a little purpliſh colour upon them, yet ſo as the whiteneſſe appeareth ſtill.

8. *Leucoium Creticum oblongis foliis crenatis.* Long leafed *Candy* Stocke Gilloflower.

This third *Candy* kinde hath longer leaves, than either of the two laſt, plainely dented about the edges, from among which ariſeth a round ſtalke, not halfe a foote high, ſending forth diverſe branches ſtored with as ſmall flowers as the laſt, but of a deeper blewiſh purple colour, than the firſt *Candy* kind.

9. *Leucoium Creticum marinum Cœruleum.* The blue *Candy* Stocke Gilloflower.

This ſmall *Candy* kinde hath many ſmall greene hayrie and ſtraked ſtalkes, not much above an hand breadth high, having for the moſt part, two or three whitiſh ſoft greene leaves, ſet together at a place, and ſome alſo ſtanding ſingly, each of them being ſomewhat like the other Stocke Gilloflower, but round and broad at the ends,

ends, with long foote ſtalkes under them: the toppes of the ſtalkes are parted into ſmall branches, each whereof ſuſtaine ſundry ſmall flowers, ſomewhat long, made of foure leaves a peece, of a faire blue colour, after which come ſmall blackiſh ſeede in long cods like the other: the roote is ſmall and ſlender periſhing yearely after ſeede-time, yet abideth a winter from the ſeede; but ſowen in the ſpring groweth quickly to flowring and ſo continueth in flower moſt part of the Summer. You have a branch hereof expreſſed in the table with *Leucoium luteum utriculato ſemine* in the next Chapter.

10. *Leucoium ſaxatile Thymifolio.* Small Rocke Stocke Gilloflower.

The Rocke Stocke Gilloflower for the beauty of the flowers is not unfitly placed here among this Tribe, which elſe for other reſpects might more truly in my judgement be put in that *Claſſis* of the *Thlaſpia*, as the deſcription ſheweth) is a ſmall low plant, having hairy ſmall leaves like unto thoſe of time; ſet very thicke on both ſides of the weake ſtalkes, which doe lye in ſuch a round compaſſe that it ſeemeth like a ſmall round buſh, of an evill or ſtinking ſent, but ſharpe biting taſte, comming nearer to the degree of a *Thlaſpi* then *Leucoium*, as *Columna* ſaith himſelfe, who ſetteth it forth: it beareth ſmall flowers plentifully on the toppes of the ſtalkes and branches, of a blewiſh purple colour, the middle part being of a whitiſh yellow with divers ſmall threds ſtanding in the midſt of them.

The Place.

The firſt was brought out of the Iſle of *Ree* by *Rochel* by Mr. *John Tradeſcant* when the Duke of *Buckingham* was ſent with ſupplies for Mounſieur *Subiſe*: the ſecond growes by the Sea ſide, as the third and fourth about the Sea coaſts in *Narbone*, not farre from *Mompelier*, and on the coaſt of *Portugall* and *Spaine* beyond the *Straights*: the fift neare the Sea at *Terracina*: the three firſt *Candy* kinds *Cluſius* ſaith hee received from *Caſabon*, having brought them out of *Candy*: the ninth *Bauhinus* ſaith was brought out of *Signor Contareni* of *Venice* his Garden, but *Alpinus* ſaith from *Candy*, the tenth *Columna* found on the hills *Valvenſes* in *Naples*.

The Time.

They doe all flower in the Summer moneths of *Iune* and *July* for a great while, and the ſeede ripeneth not untill *Auguſt*.

The Names.

The Greeke word λεύκοιον is given to all theſe wilde plants as well as to the other of the Garden, entreated of in my former booke, whether they be thoſe we call Stocke Gilloflowers or Walflowers: for ſo *Dioſcorides* and *Pliny* and the reſt that follow him, have diſtinguiſhed the *Leucoium* (as the Latines alſo call them) into three colours, white, purple and yellow, for of a blew one as ſome copies of *Dioſcorides* have it there is ſome doubt among many writers, in that *Pliny*, *Oribaſius* and *Serapio*, all following the Text of *Dioſcorides*, and as *Marcellus* ſaith the Text of *Dioſcorides* alſo in the *Sclavonian Longobardian Characters* hath no mention at all of a blew one, but this word λευκοίον *Leucoium* that is, *Viola alba*, here is not oppoſed unto μελάνιον *Melanium* (which ſignifieth *Viola nigra*, and are our March Violets, white or purple as the compoſure of the Greeke words import) in that ἴον properly is *Viola*, but is impoſed upon theſe plants, as the proper names to them; for ſo *Dioſcorides* divideth them into ſeverall places and Chapters, from the whitneſſe of the leaves rather then of the flower as I thinke, and yet the name *Leucoium* is ſo variouſly tranſferred to other plants in *Dioſcorides* text, that the flowers of many herbes, much differing one from another, are referred by *Dioſcorides* to the flowers of *Leucoium*; and ſo *Pliny* ſaith, that the name of Violets in his time were given to very many flowers, that were put into garlands for the beauties ſake and ſweete ſavour of the flower, cuſtome prevaling above reaſon, yea many other nations in the like manner, have followed them and called them Violets, as *Viola Damaſcena* or *Matronalis* which are our Dames Violets or Winter Gilloflowers, & thoſe in *Italy*, *Viola marina*. The firſt hath the name in the title as is fitteſt for it in my judgement. The ſecond *Lobel* calleth *Leucoium marinum alterum latifolium*. *Camerarius Leucoium marinum aliud*, and ſaith *Anguilara* tooke it for *Tripolium*, and *Bauhinus Leucoium marinum latifolium*, and doubteth whether it be not the *Leucoium maritimum minus* of *Lugdunenſis*, which as he ſaith ſome tooke to be *Heſperis*. The third and fourth are *Cluſius* his *Leucoium marinum majus* and *minus*, and ſo doe *Lobel* and *Camerarius* call them, *Bauhinus* calleth them *marinum latifolium* and *anguſtifolium*: the fift *Bauhinus* onely mentioneth by the ſame name in the title: the ſixt, ſeventh and eighth *Cluſius* calleth, *Leucoium marinum Creticum primum, ſecundum & tertium*: the ninth *Bauhinus* thinketh to be that *Leucoium Creticum pulcherimum*, *fortè Leucoium cæruleum Dioſcoridis*, that *Pona* mentioneth in his deſcription of Mount *Baldus*, and calleth it himſelfe *Leucoium Creticum minimum folio ſubrotundo*, and after a ſort deſcribeth it in his *Prodromus*, and peradventure may be his ſixt ſort there deſcribed likewiſe, for I finde little difference the one from the other: but *Alpinus libro de plantis exoticis* deſcribeth it more perfectly and exactly, and calleth it *Leucoium cæruleum marinum*. The laſt *Columna* hath ſet forth by the name of *Lithoreo Leucoium minimum ſupinum*, and *Bauhinus Leucoium ſaxatile thymifolio hirſutum cæruleo purpureum*, but might as I ſayd be rather accounted a *Thlaſpi*.

The Vertues.

Theſe wilde or Sea Stocke Gilloflowers are of the ſame qualitie with thoſe of the garden ſaving that they are not of ſo ſweete a ſent, and are almoſt eſteemed as effectuall as the ordinary yellow *Leucoium* or Wallflower, for ſo is *Galens* judnement of them all, ſaying they are of a clenſing qualitie and of thinne parts: the Garden Stock Gilloflowers (for under them I comprehend the vertues of theſe alſo as I ſayd) eſpecially the dryed flowers, rather then the freſh and greene boyled in wine and drunke doth rectifie the indiſpoſition of the Liver and reines, provoketh womens courſes, as alſo helpeth the hardneſſe and paines of the mother, and expelleth the ſecondine or afterbirth, and the dead child alſo, yea and the living alſo ſaith *Galen*, if they ſhall drink of it when it is quick; a bath made for them to ſit in doth the ſame, & the ſeed or the juice drunk worketh in the ſame manner alſo. If the ſame be drunke twiſe a day, it will helpe to ſtrengthen and reſtore any member growne weake, looſe, or out of joynt; the decoction of the rootes in vinegar, is held good for the hardneſſe of the ſpleene, to be uſed outwardly, as well as inwardly. The diſtilled water of the flowers is availeable, to all the purpoſes aforeſayd, and is ſayd to clenſe the blood, to comfort the inward parts, to eaſe paines and to procure a merry diſpoſition: the leaves bruſed with ſalt is uſed as a remedy for the Ague, to be tyed to the wriſtes: The juyce dropped into the eyes doth clenſe them from the miſts and clouds, that ſeeme to hinder the ſight, and ſuch filmes or skinnes, that beginne to grow over the ſight to take it quite away: it is good alſo to gargle the mouth, with the decoction of the flowers,

flowers, and ſome honey put to it, and a little allome, and is found good for ulcers and ſores therein, as alſo all other old and filthy ulcers: boyled alſo in Vinegar and applyed warme upon the place pained by the Goute, giveth a great deale of eaſe, as alſo to the joynts and ſinewes that have weakeneſſe and paines, or are troubled with hard tumours, ſwellings, or inflammations.

CHAP. LXXIII.

Keiri ſive Leucoium luteum. Wallflowers.

I Have in my former booke, ſhewed you all or moſt of thoſe Wall-flowers that carrying beautifull flowers are received as the delights and ornaments of a garden of Pleaſure. I there alſo declared that there were ſome other, of no ſuch beauty, or ſent fit for that place, and therefore to be referred to this, as ſhall be now ſhewed you.

1. *Keiri ſive Leucoium montanum luteum.* The Mountaine Wall-flower.

The Mountaine Wallflower riſeth up with divers upright, ſtrong, and wooddy ſtalkes, as high as any man ſometimes, beſet with many ſhort greene pointed leaves, dented about the edges: the flowers are ſingle, but larger than of the ordinary ſort, and of a faire yellow colour, conſiſting of foure leaves, ſmelling very ſweete like them, the long pods that containe reddiſh ſeede, are ſomewhat ſlenderer than the other: the roote is wooddy diſperſed under the ground into branches, and endureth long eſpecially in the warmer Countries, where the froſts are not ſo extreame, as they are with us.

2. *Keiri ſeu Leucoium ſylveſtre Cluſii.* Wild Wallflowers of *Cluſius*.

This wild Wallflower, hath ſometimes many, and ſometimes but one head of long narrow greene leaves, lying on the ground about the roote, ſomewhat like unto the ordinary Wallflower, but a little waved or ſparingly dented about the edges, which ſo abide the firſt yeare for the moſt part; yet ſome the yeare of their firſt ſpringing will ſend forth a ſtalke or two, of about a yard high, with many ſuch like leaves ſet thereon, as grew below, but ſmaller and with few or no dents on the edges at all: the flowers are many that ſtand cluſtring together, as it were in an umbel, (and not in a long ſpike, as the ordinary Wallflower doth at the toppes) conſiſting of foure leaves a peece, not altogether ſo large as the Wall-flower; nor of ſuch a yellow colour of little or no ſent at all: after which come long ſlender pods, with flattiſh ſeede in them like the other: the roote is long and ſingle, with divers fibres therear, and periſheth after ſeede time.

3. *Leucoium luteum Erucæ folio.* Wallflowers with jagged leaves.

This kind of Wallflower, hath his lower leaves much more and deeplier jagged on the edges, (almoſt like

Keiri ſive Leucoium vulgare luteum vel album.
The ordinary yellow Wallflower or the white.

2 Keiri ſeu Leucoium ſylveſtre Cluſii.
Wilde Wallflowers of *Cluſius*.

thoſe of Rocket, or of the wilde Poppie) than thoſe upon the ſtalke, yet all of them very long greene and ſoft and ſomewhat hayrie: the ſtalke which is round and ſomewhat hayrie, about two foote high, and ſomewhat branched, beareth many yellow flowers, like the common Wallflower, but ſet more cloſely together, as it were in an umbell, and of the ſmell of new Waxe: but afterwards doe more ſeparate a ſunder, when it beareth the long pods like unto the other; the whole plant hath a ſharpe quicke taſte.

4. *Leucoium Creticum luteum utriculato ſemine. Candy* Wallflowers with roundiſh pods.

From a ſmall Wooddy roote divided into ſundry branches, riſe up divers wooddy ſtalkes, about a foote high, branching forth and ſet at ſeverall places, with many ſmall whitiſh greene leaves ſet together, leſſer than thoſe of the ordinary ſort, harder in handling and ſet with ſharpe haires: the flowers are yellow at the toppes of the branches, made of foure round pointed leaves a peece uſually, but ſometimes with foure or ſixe, after which come yellowiſh roundiſh pods, conteining many whitiſh ſeedes, like unto the ordinary but broader and greater, this abideth with ſome leaves greene above ground in the winter, not periſhing as many others doe.

The Place.

The firſt *Pona* hath ſet forth, in the deſcription of Mount *Baldus*, in his *Italian* Edition, but not in the Latine, found growing there: the ſecond groweth in *Germany*, in many places, as *Geſner*, *Tragus*, *Camerarius*, and *Cluſius* make mention: and in *Spaine* alſo, for from thence hath the ſeedes thereof beene brought to me: the third *Columna* ſaith groweth in the vallies of the *Campoclare* hils in *Naples*: the fourth in *Candy*,

The Time.

They flower almoſt all the Sommer long, and in the meane time ripen their ſeede.

The Names.

I have ſhewed you in the Chapter, next before this, the Greeke and Latine names to be *Leucoium*, and the derivation and tranſpoſition thereof, to many other herbes; whereunto I referre you, onely theſe yellow kinds, as well as the other ſet forth in my former booke, are called *Leucoium luteum*, or *aureum*, as a diſtinction to ſeverthem: the *Arabians* doe properly call this yellow kind *Keiri*, or *Cheiri*, although divers doe transferre the name, to all the other ſorts of *Leucoium*; but becauſe this is more excellent and vertuous, than any of the Stocke Gilloflowers, even by *Galen* his judgement. I hold the name *Keiri*, more proper to this kinde than that; ſome alſo call it *Viola lutea*, as *Tragus*, *Fuſchius*, *Dodonæus*, and *Cæſalpinus*, but *Tabermontanus Viola petræa lutea*: The firſt here ſet downe is called by *Pona* aforeſayd, *Leucoium luteum montanum ſerrato folio*: the ſecond is called *Leucoium ſylveſtre* by moſt writers thereof; by *Tragus Viola lutea ſylveſtris*: it is very probable that it is the ſame alſo, that *Beſlerus in horto Eyſtetenſi*, calleth *Leucoium ſylveſtre inodorum flore flavo pallidore*, as alſo the *Leucoium ſylveſtre* of *Cluſius*, although *Bauhinus* would make them two ſeverall plants, calling the one *Leucoium luteum ſylveſtre Hieratii folio*, and the other *Leucoium luteum ſylveſtre anguſtifolium*: the third *Columna* calleth *Leucoium terreſtre majus*, and *Bauhinus Leucoium luteum Erucæ folio*: the fourth is onely found extant in *Alpinus de plantis exoticis* by the ſame name is in the title: the *Italians* call it *Viola Gialla*: the *Spaniards Violas amarillas*: the *French Violas Iaunes & Violes des Mares*: the *Germanes Geell Violen*, and Winter *Violen*: the *Dutch Steen Violeren*: we in *Engliſh* Wall flowers, Wall Gilloflowers; Winter Gilloflowers, and ſome Bell flowers, and yellow Stocke Gilloflowers.

4. *Leucoium Creticum luteum utriculato ſemine & Marinum Creticum cæruleum.*
Yellow Stocke Gilloflowers with round heads, and the leaſt *Candy* kinde with blue flowers.

The Vertues.

All writers doe atttribute the moſt eſpeciall vertues, of all the ſorts of *Leucoium*, to the *Leucoium luteum*, which is our common Wallflower: and ſome of theſe wilde kindes here expreſſed, doe come ſo neere thereunto, although wanting that ſweete ſent that they may be uſed in their ſtead; for even theſe are ſomewhat bitter and hot, and conduce (but eſpecially the ordinary or ſweete kindes) unto all the purpoſes that are ſpecified in the former Chapter; for *Galen* ſaith in his ſeventh booke of ſimple medecines, that the yellow *Leucoium* doth worke

worke more powerfully than any of the other kindes, and therefore of more uſe in Phiſicke: it cleanſeth the blood and freeth the Liver and reines from obſtructions, provoketh womens courſes, expelleth the ſecondine and dead child, helpeth the hardneſſe and paines of the mother, and of the ſpleene alſo: ſtayeth inflammations and ſwellings, comforteth and ſtrengthneth any weake part, or out of joynt; helpeth to cleanſe the eyes from miſtineſſe and filmes growing on them, and to cleanſe foule and filthy ulcers, in the mouth or any other part, and is a ſinguler remedy for the Goute, and all aches and paines in the joynts and ſinewes.

CHAP. LXXIIII.

Heſperis ſive Viola Matronalis. Dames Violets.

HAve in my former booke ſet forth two ſorts of Dames Violets, both of them with ſingle flowers, but the Preſſe had ſcarſe paſſed that Chapter, where I mentioned them, but I did underſtand of two others, with double flowers, the one that was ſent me from *Paris*, and yet was in *England* long before, as I underſtood afterwards, although I heard not of it; and another likewiſe nurſed up with the other, in the Weſt parts of our Land, which I meane to declare unto you here, (and may be transferred to the other ſingle ones, when that booke ſhall be reprinted) together with ſome other ſorts hereof.

1. *Heſperis ſive Viola Matronalis flore albo pleno.* Double white Dames Violets.

The double white Dames Violets groweth not ſo great in any part thereof, nor ſo high as the ſingle doth, except in the flowers, which being very thicke of leaves, of a pure white colour, and many ſtanding in a cluſter, ſweeter alſo than the ordinary, and longer abiding, cauſeth it to be had in ſome eſteeme; it hath ſomewhat leſſer leaves of a freſher greene colour, little or nothing ſnipped about the edges, and more tender; but the branches grow more plentifull, and more eaſie to be ſlipped and tranſplanted, than the ſingle kinde, but giveth no ſeede, as many other plants doe, that carry double flowers, and is more tender to be kept in the Winter.

2. *Heſperis flore pleno purpurante.* Double purple Dames Violets.

This other double Dames Violets differeth not much in any thing from the former, but in the colour of the flowers which in this is of a fine pale purpliſh colour, and not fully ſo double as the others, nor ſo many cluſtring together.

Heſperis Melancholica.
The Melancholy Gentleman.

Heſperis Syriaca Camerarii, &
5. Sylveſtris latifolia flore albo parvo.
Dames Violets of Syria, and the ſmall white flowred Dames Violets.

3. *Hesperis Pannonica inodora.* Vnsavory Dames Violets of *Hungary.*

This *Hesperis* is so like unto the ordinary sort, in all other things saving the sent, that there can be no difference found betweene them: this onely hath no sent at all, neither morning, nor evening, neither day, nor night, to commend it, which maketh it to be a differing sort from the rest: and some have made another different sort hereof, (which is likely to be but a degeneration of the same) that beareth greenish flowers.

4. *Hesperis sylvestris folio sinuato.* Wilde Dames Violets with waved leaves.

This Dames Violet sendeth forth an hairy, rough, crested, pale greene stalke of about a foote high, parted at the top into divers branches, with leaves set thereon from the bottome, which are thicke, rough, and hairy, narrower and longer then the other, and waved about the edges, the lowest having footestalkes, and those above none, but stand close to the stalke: the flowers are as large, and consist of foure leaves in the same manner that the rest doe, and smelleth pretty sweete also, but of a deeper red colour then they: the cods with seede in them are like the other and perish after seede time most usually, yet sometimes abiding a third yeare of it selfe, but most certainely if it be hindered from bearing too many branches and flowers, by cutting them downe before they goe to flower.

5. *Hesperis sylvestris angustifolia flore parvo.* Small purple floured Dames Violets.

The leaves of this small *Hesperis* are narrower and longer pointed then in the common sorts, lesse rough also and deepelier cut in or dented on the edges: it hath a stalke about halfe a yard high, branched toward the toppe with very small flowers thereon, of a purplish colour, so that one of these flowers, are not much bigger then one of the leaves of the flower of the ordinary; the pods that follow are long but much smaller.

6. *Hesperis sylvestris latifolio flore albo parvo.* Small white flowred Dames Violets.

The leaves of this kinde are large and broad, small at the bottome of the stalke where it is a little parted or torne, but crumpled and dented all about the edges, a little rough hairy and woolly, but in Summer more white: the stalke riseth up the next yeare after the first springing about a yard high, branching forth at the top into sundry long spikes, full of very small white flowers no bigger then the last, consisting of foure leaves a peece, which afterwards yeeld very many and very long slender flat pods like the Stocke Gilloflowers hanging downe, but smaller, with very darke browne flat seedes therein on both sides like the *Leucoium*: so that it partaketh with the *Hesperis* in the greene leaves, and with the *Leucoium* in the flat pods and seede: the roote is not very long but white and wooddy perishing yearely after it hath borne seede: the flowers have little or no sent in them; but the leaves have a little hot and drying taste. I have given you onely a leafe hereof, and a few flowers at the sides of the *Hesperis Syriaca.*

Because both the *Leucoium Syriacum* and *Melancholium*, that I have set forth already in my other booke, as I there call them, partake more with this *Hesperis* then with *Leucoium*, in that their leaves are greene, and not white like them; and in that the seede in the pods of the *Melancholium* are not flat but long and round like *Hesperis.* I have given you here the figure thereof, and with the *Syriacum* a leafe and some flowers of the last: I might have multiplyed the sorts of *Hesperis* unto you as *Bauhinus* doth if I would follow him, who maketh that *Leucoium alterum saxatile obsoleto flore* of *Columna* to be of a different sort from the *Melancholium*, which undoubtedly is the same, and the *Hesperis Syriaca* or *Leucoium Syriacum*, of *Camerarius*, and *Clusius* to bee the *Leucoium Melancholium* also, which certainely also are differing plants, and even *Bauhinus* himselfe would so have acknowledged, if ever he had seene both the plants.

The Place.

The first was as I sayd before sent me first out of *France*, which perishing I had both it againe and the second also by the liberalitie of Mr. Dr. *Anthony Sadler* a Physitian in *Exeter*, son to the elder *Sadler* an Apothecary there, who both affirmed unto me for certaine, that the white one was in many mens Gardens in the West parts, and the purple also although not so plentifull, before my booke came forth, but from whence the originall of them came is not knowne: the third as *Clusius* saith groweth in the skirts of the vineyards at the foote of the hills, that are neare *Vienna* in *Austria*: the fourth groweth as *Bauhinus* from *Burserus* relateth it, among the stony places in *Proevnce* that are moystned with springs: the fift also neare *Mompelier*, in the watery gravell grounds, on *hortus Dei*: the last grew in my garden from seede, receaved from some friend but I have forgotten who.

The Time.

They all doe flower in the Summer Moneths of *Iune* and *Iuly* chiefly, and the first abideth longest, if it stand not too much in the Sunne.

The Names.

There is some doubt among many learned, whether this *Viola Matronalis*, as it is usually called in Latine, should be the *Hesperis* of *Theophrastus*, in his sixt Booke *de causis plantarum* and 25. Chap. because he is so briefe therein, that there can be no more learned out of him, then that it smelleth sweeter in the morning and evening then in the day time, even as some of these and the ordinary sort doth, whom *Pliny* followeth in his 20. Booke and 7. Chapter, and thereof tooke the name *Hesperis*: It is also called of *Tragus Viola alba*, and *Persica Hermolai*, and taken to be *Leucoium* of *Fuschius*: *Gesner*, *Dodonæus* and *Lugdunensis* call it *Viola Matronalis*, and *Lobel Viola Damascena.* Some also call it *Viola hyberna*, *sive hyemalis*, and some *Viola Moschatella*; the first and second are called *Hesperis flore pleno albo*, and *flore pleno purpurante*: the third here is the third *Hesperis* of *Clusius*, and the other two are mentioned by *Bauhinus*, the former by the name of *Hesperis sylvestris hirsuta folijs Hieratij*, the other *Hesperis sylvestris flore parvo*, to the last I have given the title as is fittest: the *French* call them *Violette de Damas*, and *Violette de Dames*, *Giroflee di Damas*, and *Giroflee de Dames*, the *Germans winter Violen*, as they doe the Wallflowers also in the last Chapter, the *Dutch Damas Bloemen*; we in *English* Dames Violets, and Damaske Violets, Queenes Gilloflowers, Winter Gilloflowers, also of some, Rogues Gilloflowers, but why I know not: in the West parts of this Island, from whence I had the double kinds as I am enformed, they call it double Sciney, and the single close Sciney, but *Gerard* saith close Sciences.

The Vertues.

Hesperis, all the sorts of them are hot and sharpe in taste, like unto Rocket, and therefore *Dodonæus* thinketh they may be *species* thereof, being so like in taste, to be also in propertie: he saith that the distilled water thereof is very effectuall to procure sweating. *Clusius* further addeth, that it provoketh Vrine also, and helpeth those that

have

have a cough or are ſhort winded: it is alſo of a cutting quality for tough flegme, of a digeſting property for raw and undigeſted humours, and of a clenſing nature for foule and filthy Cankers, Vlcers and ſores, eyther inwardly in the mouth, or outwardly in any part of the body.

CHAP. LXXV.

Lychnis. Campions.

I Have given you a doſen ſorts of Campions in my former booke which are all delightſome and pleaſant plants fit for that worke, being A Garden of Pleaſure: there are many other ſorts to bee entreated of which ſhall be here exhibited, even to the leaſt ſort which is like Moſſe upon the ground, that ſo you may underſtand all the varieties that nature hath ſhewed us, and becauſe two ſorts with double flowers, are come to our knowledge ſince the publication of my booke, which elſe ſhould have beene therein inſerted, and may bee at the next Edition. I will begin with them firſt in this Chapter, and adde unto them a ſmaller ſort of ſingle not there expreſſed, and of the reſt in the other following, yet give you the Figure of the ſingle kinde and declare the properties.

1. *Lychnis Coronaria flore albo pleno.* Double white Roſe Campions.

The double white Roſe Campion hath not altogether ſo woolly white leaves, as the other Roſe Campions have, but are a little greener and ſmaller, the flowers grow upon the branches of the ſtalke in the ſame manner but riſe not uſually ſo high as the double Red, ſet in whitiſh cornered huskes, and conſiſting of two or three rowes of leaves in the ſame manner; this is a little more tender to keepe then the double Red, and deſireth more ſhadow and moyſture.

2. *Lychnis Chalcedonica flore albo pleno.* Double white Noneſuch.

This double Noneſuch is ſo like unto the other double Red, for the forme of the leaves and manner of growing, as that there is hardly any difference diſcerned before it come to flower, yet the leaves ſeeme to bee a little freſher greene: the ſtalke riſeth not ſo high, and the flower it ſelfe is not ſo large as the double red and is of a pale whitiſh colour.

3. *Lychnis Chalcedonica minor ſimplex.* The leſſer ſingle Noneſuch or flower of Briſtow.

The leſſer kinde riſeth not ſo high as the other ſort by the halfe, neither is the ſtalke ſo great having but a few leaves ſet thereon by couples like the other: the flowers that ſtand at the toppe likewiſe are fewer but of the ſame colour, the roote is ſmall and fibrous and periſheth every yeare.

The Place.

Theſe are onely nourſed up in Gardens with us, and their naturall places are not knowne.

The Time.

They both flower at the time of their other kinds.

The Names.

It is called in Greeke λύχνις (*Lychnis*, from λύχνος *i. Lucerna*) and ἐλλύχνιον *Ellychnium quaſi lucernæ funicu-*

Lychnis Coronaria vulgaris.
Ordinary Roſe Campion.

Lychnis Chalcedonica vulgaris.
The ordinary Noneſuch or flower of *Briſtow.*

lum and thereof tooke the name, for in the former times they uſed the leaves of the Campions, as of many other plants in their lampes inſtead of the week to burne. The ſingle kind is called alſo by divers other names, as *Vallaria*, or *Ballaria*, *Geniculatis*, and *Corymbe* of *Columella*, in his tenth booke, as *Ruellius* thinketh, where *Columella* hath this Verſe:

Nunc veniat quamvis oculis inimica Corymbe. Vnleſſe he underſtand Crambe thereby.

The Greeks alſo called it ἀθάνατον, *i.e. immortalis, quod diutius vennſtatem ſuam retinet*, and ſome *Taurion* but not *Taura* or *Tora*, which is a venemous plant as I have ſhewed before; in Latine moſt uſually they call it *Lychnis ſativa* or *Coronaria* and *Sylveſtris*, *Cordus* calleth it *Verbaſcum montanum*. Some have taken this to be the διὸς ἄνθος of *Theophraſtus* in his ſixt booke and ſeventh Chap. but that cannot be, for he reckoneth both *Lychnis*, and *Dioſanthos* among the Summer flowers; ſome alſo to be his φλὸξ *Flamona*, but hee mentioneth that alſo in the ſame place, and cannot be both one herbe. *Pliny* in his 21. booke and fourth Chap. ſaith they called an herbe *Roſa Græca*, which the Greekes called *Lychnis*, and in the 11. Chap. of the ſame 21. booke he nameth *Lychnis* as *Theophraſtus* doth among the Summer flowers: the Garden kind therefore as fitteſt for the uſes aforeſaid is held by the moſt judicious in theſe times to be the true *Lychnis* of *Theophraſtus* and *Dioſcorides*: the *Italians* call the *Lychnis ſativa Lychnide ortolana*, and the wilde *Lychnide ſylveſtre*: the *French*, *Oeillet Dieu* for the Garden kind, and *Oeilet ſauvage* for the wilde: the *Germans* call the manured ſort *Frawwenroſzlin*, *Marienroſzlin*, and *Himmelroſzlin*, that is to ſay, *Dominarum Roſa*, *Mariana Roſa*, *Cæli Roſa*, and *Cæli flos*: they call the wilde kind *Margenroſzlin*, and wild *Margenroſzlin*, the *Dutch* call the Garden kinde *Chriſtus coghen*, and the wild *Iennettekins*, and wee in *Engliſh* Roſe Campions thoſe of the Garden and the other wilde Campions, as you ſhall heare in the next Chapter. The other Campion (as well the ſingle as double kindes) is called *Lychnis Byzantina*, *Chalcedonica*, *Conſtantinopolitana* of ſome, *flos Creticus* of others, and *flos Hieroſolomitanus* of *Geſner*, who alſo calleth it *Ocimoides peregrinum*, and *flos Conſtantinopolitanus* of *Lobel*, *Lugdunenſis*, and others: wee in *Engliſh* uſually call it Noneſuch, Flower of *Briſtowe*, and flower of *Conſtantinople*. It is thought by ſome to be *Struthium* or *Lunaria*, which the *Arabians* call *Condiſi* becauſe it will make water to lather like ſope, and clenſe ſuch cloathes as are waſhed in it: but yet notwithſtanding that quality (which is alſo given to *Saponaria*, and thereby alſo thought to bee *Struthium*) it agreeth not with the deſcriptions of *Theophraſtus* and *Pliny* (for *Dioſcorides* deſcribeth it not) which as they ſay is a thorny plant bearing leaves like unto an Olive, and hath a great roote, none of all which this plant hath, and therefore cannot be it. Some likewiſe thinke it to bee *Pothos* of *Theophraſtus* in the ſame ſixt Booke and laſt Chapter, which *Athenæus* agreeing with him ſaith is of two ſorts, the one *Hyacintho ſimilis*, the other ἀχρῶς, *id eſt*, *decolor*, *non coloratus*, *vel ſine colore*, and may very well agree with the ſeverall colours of the flowers hereof. The ſecond or leſſer ſort is very like to be the *Flos coccineus* of *Lugdunenſis*, and the *Ocimoides peregrinum minus*, or *Flos ab Hieroſolimis minor* of *Geſner in hortis*, and not the *Muſcipula Lobelij* or *Lychnis ſylveſtris prima Cluſii* as *Bauhinus* maketh the doubt, for *Geſner* there ſaith, that the leſſer ſort endureth long and hath fewer flowers.

The Vertues.

The Roſe Campions are of little uſe in Phyſicke now adayes with us, being chiefly uſed as flowers, fit to decke the Garden or the houſe, *Galen* ſaith that the ſeede thereof is hot in the ſecond or third degree, and dry in the ſame, and *Dioſcorides* ſaith that the ſeede of the Roſe Campion drunke in wine doth helpe thoſe that are ſtunge by a Scorpion; which if it be true and ſo found now a dayes; I ſee no reaſon but the ſame might bee availeable for the peſt, it being as ſpeedy a poyſon, apt to kill in a ſhort ſpace: and beſides that wee have many things effectuall againſt the Plague, which will expell alſo the poyſon of the Scorpion, or other venemous beaſts: the leaves applyed to any old or foule Vlcers in the Legs or other parts, doe clenſe and heale them. Of the Noneſuch, there is neither ancient nor moderne writers hath given any property, but is wholly neglected of all.

CHAP. LXXVI.

Lychnis ſylveſtris. Wilde Campions.

BEcauſe I have many ſorts of *Lychnides ſylveſtres*, wilde Campions to declare unto you: I thinke it the fitteſt and moſt methodicall way, to diſtinguiſh them into ſeverall Chapters, and entreate of them ſeverally, that ſo both my writing and your reading be not confounded nor they with it. I meane therefore to entreate in this Chapter of thoſe wilde ſorts that beare rough leaves and ſtalkes, and grow high; in the next of thoſe that are glutinous and clammy; and laſtly of thoſe that eyther bend or lye downewards to the ground, or creepe thereon, and of thoſe that are ſmall, or that are like Moſſe upon the ground.

1. *Lychnis ſylveſtris flore albo.* White wilde Campions.

The white wilde Campion hath many long and ſomewhat broad darke greene leaves lying upon the ground, with divers ribbes therein ſomewhat like unto Ribwort Plantaine, but ſomewhat hairy, broader, and not ſo long: the hairy ſtalkes riſe up in the middle of them, three or foure foote high, or ſometimes more with divers great white joynts at ſeverall places thereon, and two ſuch like leaves thereat up to the toppe, ſending forth branches at the ſeverall joynts alſo; all which beare on ſeverall footeſtalkes white flowers at the toppes of them, conſiſting of five broad pointed leaves, every one cut in on the end, unto the middle, making them to ſeeme to be two a peece, ſmelling ſomewhat ſweete, and each of them ſtanding in large greene ſtriped hairy huskes, large and round below next the ſtalke: the ſeede is ſmall and grayiſh in the hard heads that come up afterwards: the roote is white and long, ſpreading divers fanges in the ground.

2. *Lychnis ſylveſtris flore rubro.* Red wild Campions.

The red wilde Campion groweth in the ſame manner as the other, but his leaves are not ſo plainely ribbed, ſomewhat ſhorter, rounder, and more ſoft or woolly in handling: the flowers are of the ſame forme and bigneſſe, but in ſome of a pale, and others of a bright redd iſh colour, cut in at the ends, more finely, which maketh the jagged leaves ſeeme to bee more in number than the other: the ſeede is like, and ſo is the roote alſo: the rootes of both theſe ſorts doe not periſh after ſeede time, but abide many yeares.

3. *Lychnis*

1.2. *Lychnis sylvestris flore albo vel rubro.*
The white or red wild Campion.

4. *Lychnis sylvestris caulibus striatis.*
Wild Campion with straked huskes.

5. *Lychnis sylvestris alba minor.*
The smaller white wilde Campion.

6. *Lychnis sylvestris angustifolia.*
Narrow leafed wilde Campion.

3. *Lychnis ſylveſtris rubra minor.* The leſſer red wild Campion.

The leſſer red wild Campion, is very like the former red ſort, but ſmaller, and lower, yet very much branched, and with darker greene leaves: the flowers are reddiſh, but ſmaller, and not ſo much dented in at the ends: the huskes and ſeede, are like the other, but ſmaller, and the roote periſheth after ſeede time.

4. *Lychnis ſylveſtris caliculis ſtriatis.* Wild Campions with ſtraked huskes.

This wild Campion riſeth up with a round joynted ſtalke, with two greene leaves a peece at them, narrower and ſmaller pointed then thoſe before, and branched, bearing ſmall flowers of a ſullen reddiſh colour, parted at the ends, ſtanding in large hard skinnie huskes, ſtriped or ſtraked with white and greene, the ſeede is more gray than the other: the roote is ſmall, growing downeright, with a few fibres thereat, and periſheth every yeare.

5. *Lychnis ſylveſtris alba minor, ſive Ocimoides minus album.* The ſmaller white wild Campion.

The ſmaller white Campion, is ſomewhat like unto the firſt wild Campion, but that his greene leaves, have as it were no ſtalkes, and are not ſo full of veines or ribbes, much leſſe alſo and narrower than they, ſomewhat hayrie likewiſe, and pointed at the ends; but thoſe that riſe up with the ſtalke, and ſtand at the joynts one oppoſite to the other, doe as it were compaſſe the ſtalke, being leſſe, and leſſe, up to the toppes; where come forth ſmall branches, with two or three or more white flowers upon them, ſmaller then the former, and more divided or cut in, with ſome white threds in the middle, which when they begin to decay, doe twine their leaves inward, after which come ſmall grayiſh ſeede, in ſomewhat large pointed huskes: the roote is ſomewhat great and yeeldeth new ſhoots every yeare.

6. *Lychnis ſylveſtris anguſtifolia.* Narrow leafed wild Campions.

This wild Campion hath divers narrow long whitiſh greene leaves, lying on the ground, from whence the next yeare after the ſpringing riſeth up a ſtalke, divided into branches from the joynts, whereon grow leſſer and narrower leaves than thoſe below, ſometimes three or foure, and ſometimes more ſet together; at the toppes whereof grow ſmall flowers, made of five leaves a peece, notcht or cut in at the ends, white on the inſide, and ſomewhat purpliſh on the outſide, twining themſelves before they fall, as the laſt doth: the huskes that conteine the ſmall grayiſh ſeede, are very hard ſmall and round: the rootes are ſmall, and periſh after ſeede time.

7. *Lychnis Noctiflora.* Morpheus ſweete wild Campion.

This ſweete wild Campion, that ſmelleth ſweeteſt in the night time chiefely, and little or nothing in the day, and in the hot Sommer onely, and not toward Autumne, is but an annuall plant, riſing not a yard high, with ſmall narrow whitiſh greene leaves on the ſtalke, ſet by couples, whoſe flowers at the toppe, are of a very whitiſh bluſh colour, parted at the ends as the other are, and ſtanding in hard huskes, which will be a little clammie

8. *Lychnis ſylveſtris hirta major.* The greater haytie wild Campion.

9. *Lychnoides ſegetum ſive Nigellaſtrum.* Cockle.

in

11. *Lychnis syl. i. cana caliculis striatis.*
Hoary wilde Campion.

12. *Lychnis segetum Vaccaria rubra dicta.*
Corne Campion of the gardens.

in the heate of Sommer ſometimes, and yet but ſeldome: the ſeede is grayiſh and ſmall, and the roote periſheth every yeare.

8. *Lychnis ſylveſtris hirta major.* The greater hayrie wild Campion.

This hayrie Campion hath divers joynted hayrie ſtalkes, having two ſmall long and narrow, hayrie and hoary leaves ſet at them; branching forth, and towards the toppes ſending out from the joynts, ſeverall large flowers, upon ſhort footeſtalkes, of a pale reddiſh; or carnation colour, made of five round pointed leaves, dented or notched in the middle: the ſeede that followeth them is reddiſh, in ſuch like heads as the reſt; the roote is thick and great, yet periſheth the ſame yeare it beareth ſeede; for the firſt yeare it doth not.

9. *Lychnis ſive Lychnoides ſegetum & Nigellaſtrum.* Cockle or Corne wilde Campion.

I had rather put this Cockle in this place among the wild Campions, whereunto both in face and other properties it is moſt like, than either put it with the *Nigellas* as ſome doe, or make a Chapter of purpoſe for it. It hath *Flore albo*
an upright hayrie ſtalke, ſhooting forth branches on all ſides, with two long hayrie, or woolly ſoft leaves at the joynts: the flowers ſtand at the toppes of the branches, in hayrie long huskes, whoſe ends or points, are longer than any of the former Campions, ſtanding upright both before the flowers open, & after they are paſt, and laying themſelves betweene the five round pointed leaves, when they are blowen, which are of a bright reddiſh purple, or crimſon colour: the ſeede that followeth in hard round heads, is bigger and blacker, than in any of the former: the roote is ſmall and wooddy, periſhing as ſoone, as it hath borne ſeede. Some have obſerved a ſort hereof with white flowers.

10. *Lychnis Cretica anguſtifolia. Candy* wilde Campions.

The wild Campion of *Candy*, ſpreadeth forth many branches, from the very bottome of the ſlender hayrie ſtalke, not above a foote high, whereon are ſet two leaves one oppoſite to another, at every joynt, which are ſmall, long, and narrow, ſomewhat thicke, and woolly or hoary; at the toppe of each branch ſtandeth one ſmall flower, like unto the other wilde Campions, dented in at the ends, of a fine reddiſh colour, upon the firſt blowing and opening, but declining to whitiſh afterwards, with divers threds in the middle tipt with yellow, ſtanding in hayrie huskes, ſmall at the bottome, and larger at the toppes, the heads and ſeede are like unto the garden Roſe Campion: the roote is ſmall and fibrous, periſhing every yeare, yet riſing of the ſeede, if it be ſuffreed to ſhed it ſelfe.

11. *Lychnis ſylveſtris incana caliculus ſtriatis.* Hoary wilde Campion.

This hoary wilde Campion ſhooteth forth five or ſixe ſmall hoary ſtalkes, about halfe a foote high, with two long and narrow hoary leaves ſet at each joynt, the flowers grow 4 or 5 together being red like to thoſe of the ſea Campion, growing out of thicke ſwelling ſtraked huskes wherein afterwards the ſeede is conteined.

12. *Lychnis ſegetum Vaccaria rubra dicta.* Corne Campion of the Gardens.

This kinde of Campion is but an annuall plant and riſeth up with one round ſtalke for the moſt part, ſpreading into

into ſundry branches, having two long leaves ſet oppoſite at the joynts, being broad at the bottome, and compaſſing the ſtalke and branches, almoſt like unto Thoroughwaxe, ending in a ſmall point of a pale greene colour: at the toppes of the branches ſtand ſundry flowers, made of foure leaves a peece, of a pale red colour, after which come ſmall round and hard blacke ſeede, conteined in skinnie huskes: the roote is long white and ſomewhat wooddy: this plant for the beauty of the flowers is received among others into our gardens, and was but forgotten out of my former booke.

The Place.

The three firſt ſorts grow commonly through our Country by fields, hedg ſides, and ditches: the other ſorts have beene found ſome by *Cluſius*, and ſome by others, both in *Spaine* and *Germany*: the tenth in *Candy*; Cockle is too plentifull in our Corne fields; and the laſt in the borders of the corne fields in *Germany*.

The Time.

All theſe ſorts flower in the Sommer, ſome comming earlier than others, and ſome abiding longer than others.

The Names.

I have ſhewed you in the former Chapter, the Etymologie of the name *Lychnis*, and therefore neede not to repeate it here againe. All theſe are called *Lychnides ſylveſtres*: the firſt is thought by *Cluſius* more fitly to agree unto *Melandrium* of *Pliny*, in his 26 booke and 7. chap. then the *Papaver ſpumeum*, which *Lobel* would referre thereunto, and therefore entituleth it *Melandrium Plinii quorundam*. *Matthiolus* calleth it *Ocimaſtrum*, and *Ocimoides*, and ſo doth *Geſner*, *Durantes*, and *Dalechampius*. *Camerarius* and *Dodonæus* doe expreſſe both thoſe former ſorts, by the name of *Lychnis ſylveſtris alba & rubra* or *purpurea*, and *Lobel Lychnis ſylveſtris flore rubello* by the ſecond, which *Bauhinus* calleth *Lychnis ſylveſtris ſive aquatica purpurea ſimplex*: but why *aquatica* I know not, for in our Land I have not ſeene it grow in any watry grounds, other than ditch banks, & field ſides, &c. *Cluſius* calleth the third here expreſſed his *Lychnis ſyl. tertia* in his hiſtory which *Bauhinus* calleth *Lychnis ſylveſtris viſcoſa rubra altera*, and thinketh that to be the *Muſcipula* of *Lobel*: but *Camerarius in horto* ſaith, that the figure is not well cut, and that he meant the *Muſcipula* that is common, which he there calleth *Viſcago minor*, and is the firſt of *Cluſius* in his hiſtory, very truely ſet forth. *Bauhinus* likewiſe maketh the *Muſcipula altera* of *Lobel*, to be the *Armerius flos quartus*, of *Dodonæus*, which is the ſame firſt *Lychnis* of *Cluſius*, in his hiſtory of plants, and is quite contrary, for *Lobel* in his *Adverſaria* ſaith that that *Muſcipula*, hath a yellowiſh greene flower which all know the *Ben rubrum Monſpelienſium* or firſt *Muſcipula* hath not, but a red flower; *Lugdunenſis* calleth it *Aiſine purpurea*; *Bauhinus* likewiſe maketh a doubt whether that *Muſcipula Lobelii* called by others *Benrubrum Monſpelienſium*, or firſt *Lychnis ſylveſtris* of *Cluſius* be not the *Flos Conſtantinopolitanus minor* of *Geſner* (I doe not finde him to name *Conſtantinopolitanus*, but *Flos ab Hieroſolymis major & minor*) which otherwiſe he called *Ocimoides peregrinum*; the greater I verily thinke is the *Lychnis Chalcedonica ſimplex* as we call it; but the leſſer ſort ſurely cannot be the *Ben rubrum* or *Muſcipula*, for *Geſner* there ſaith that they both endure the winter after the bearing of ſeede which this *Muſcipula* doth not; and againe he ſaith his leſſer ſort hath *Rariores flores* but a few flowers, and that hath many; but I thinke as I ſayd before that it may be the *Flos Coccineus* of *Lugdunenſis*. The fourth is *Cluſius* his ſecond *Lychnis*, or *caliculis ſtriatis*; the fifth is the ninth *Lychnis* of *Cluſius* in his hiſtory, which *Lugdunenſis* calleth *Ocimoides minus ſive album*, and *Camerarius Odontis, quorundam flore candido*, being of the ſame kinde, I have ſet forth in my former booke, under the name of *Lychnis plumaria ſylveſtris ſimplex*, whereof it is likely *Tabermontanus* maketh mention, and *Bauhinus* putteth a *quid* upon it, as being a plant hee never ſaw or heard of before, and (whereof there is a ſort that beareth double flowers) which I there ſay is called *Armoraria pratenſis, & flos Cuculi*. *Cluſius* ſetteth them both forth by the name of *Odontitis Plinii ſimplici flore & pleno flore*; the ſixt is the eight *Lychnis* of *Cluſius* in his hiſtory of plants, which he made the firſt in his *Spaniſh* obſervations. *Bauhinus* calleth it *Lychnis ſylveſtris pluribus foliis ſimul junctis*; the ſeventh is called by *Camerarius in horto Ocimoides noctiflorum*, and *Lychnis noctiflora annua*. *Beſler* in the great garden booke of *Eyſtetenſis* calleth it *Ocimaſtrum noctiflorum flore albo*; the eighth is *Cluſius* his *Lychnis ſylveſtris quinta*, and with *Bauhinus Lychnis ſyl. lanuginoſa major*: the leſſer of this ſort is the ſixt *Lychnis ſylveſtris* of *Cluſius*, as it is ſet downe in the next chapter ſave one; the ninth is called by divers diverſely, ſome *Lychnis ſegetum*, *Lychnoides ſegetum*. *Tragus* calleth it *Githago*, and is his *Roſæ marianæ 6. genus*. *Dodonæus*, *Nigellaſtrum*, and *Anthemon*, as *Ruellius* before him called it *Anthemon folioſum*. *Brunfelſius*, and *Lacuna Nigella vulgaris*, but very erroniouſly (for if it have any reſemblance to *Nigella*, it is more in the blacke ſeede than in the flower or any thing elſe) and therefore *Matthiolus* calleth it *Pſeudomelanthium*, as divers others ſince him; *Fuchſius* and *Corda* tooke it to be *Lolium* but as erroniouſly. *Bauhinus* calleth it *Lychnis ſegetum major*, becauſe he maketh the *Alſine corniculata*, of *Cluſius* and all others to be his *Lychnis ſegetum minor*; the tenth is the ſeventh *Lychnis ſyl.* of *Cluſius*, which he alſo calleth *Cretica*, for that he had the ſeede from *Candy*; the eleventh *Lobel* ſo calleth as it is in the title, & *Lugdunenſis* from him; the laſt is called *Iſatis ſylveſtris* by *Lobel*, and *Vaçaria rubra*, as it is alſo by *Geſner*, *Dodonæus* and others; *Gloſtum* by *Anguillara*, *Thamecnemon* by *Cordus*, *Cændurdum Plinii* by ſome, and *Perfoliata rubra* by others, as *Geſner in hortis* ſaith, whereupon *Bauhinus* calleth it *Lychnis ſegetum foliis Perfoliatæ*; the *Italians* call all theſe ſorts of wild Campions *Ocimoide*, and *Baſilico ſalvatico*, the *French* and *Dutch* men are expreſſed in the Chapter before.

The Vertues.

Some have uſed the white flowers of theſe herbes, to ſtay the whites in women, as they doe the red flowers for their red courſes, but with what good ſucceſſe I know not; an old tradition being potent with many, that all red flowers or white flowers, are effectuall in thoſe diſeaſes: but it is found true by experience, that the decoction of the herbe being drunk, doth ſtay inward bleedings, and applyed outwardly doth the like: the ſame alſo being drunk, doth helpe to expell urine that is ſtopped, and gavell or the ſtone in the reines or kidnies: the ſeede drunk in wine, to the weight of two drams, purgeth the body of chollericke humors, as *Dioſcorides* ſaith, and that it helpeth thoſe that are ſtung by Scorpions, or other venemous beaſts, and may as I ſayd before, be as effectuall for the Plague; it is ſayd to be ſo effectuall againſt the Scorpion, that this herbe caſt upon, or put unto a Scorpion, doth make him of no force to envenome any; it is of very good uſe in old ſores, ulcers, cankers, fiſtulaes and the like, to clenſe them and heale them, which it worketh by the conſuming of moyſt humours falling into them; and by correcting the putrefaction of humors offending them; but the Cockle is of eſpecial propertie in all the diſeaſes afore ſayd, and beſides doth heale the itch, ſcabbes, and running ſores.

CHAP.

CHAP. LXXVII.

Lychnis viscosa sive Muscipula. Catchflie.

THe next ranke or order of wild Campions, is as I before sayd of those whose stalkes are glutinous and clammy, which now are to be entreated of in this Chapter: one of them I have already set forth in my former booke called *Muscipula Lobelij*, and therefore neede not describe it here againe, I will onely give you the figure thereof here.

1. *Lychnis sylvestris viscosa latifolia Clusii, sive Muscipula Cretica Auriculæ ursi facie.* *Clusius* his Catchflie of *Candy*.

This wilde Campion hath many leaves lying upon the ground, which are thicke fat and hoary, white somewhat like unto the leaves of the yellow *Auricula ursi*, Beares eares or *French* Cowslips smooth on the edges, and a little pointed, which doe so abide the first yeare of the springing: the stalke riseth up the next yeare to the height of two or three cubits, with two leaves at the joynts, and spreading on both sides into branches from the ground, which are glutinous or clammy, causing every light or small thing to cleave thereunto, as flies, strawes downe or the like: at the toppes whereof and the joynts next below them come forth many flowers together, standing in clusters but very small, whose small huskes containe every one of them, a small greenish yellow flower parted in two at the broad end: the seede is small and blackish in the huskes, the rootes are small and threddy.

2. *Viscaria maxima Cretica Alpini.* Great *Candy* Catchflie.

The roote of this Catchflie is white, long, and growing small downewards of a fingers thickneſſe, bearing about it a number of long leaves which are small at the lower end, growing broader to beyond the middle, and ending in a point, from among which rise up divers stalkes a foote high, with few joynts, and two small long leaves at each of them, bearing sundry white flowers at their toppes as it were in umbells, and out of them sometimes other such like small flowers will start, all of them like the ordinary Catchflie: the seede vessells that follow are small and round pointed at the end, with small blacke seede within them; the whole plant is very clammy causing every thing to sticke thereunto that toucheth it. This is not that former *Lychnis latifolia* of *Clusius*, as *Alpinus* saith, yet they are so like that any that shall judiciously view the figures without sight of the plants will surely account them both one, and therefore I give you their severall descriptions and figures also.

3. *Muscipula altera flore albo.* The white flowred Catchflie.

The other Catchflie shooteth forth divers branched stalkes, with small darke greene leaves set thereon by

Muscipula Lobelij sive Ben rubrum Monspelien sium
The *French* Catchflie.

1. *Lychnis sylvestris latifolia Clusij, sive Muscipula Cretica Auriculi ursi facie.*
Clusius his Catchflie of *Candy*.

2. *Viscaria maxima Cretica Alpini.*
Great *Candy* Catchflie of *Alpinus*.

4. *Muscipula Salamantica minor.*
The leſſer *Spaniſh* Catchflie.

couples, thē tops whereof where the flowers ſtand, and under them alſo are ſo clammy that it will ſticke to the fingers of them that touch them, eſpecially in the heate of the day, and in the hot Summer time: the flowers are ſmall and white, made of five leaves notched at the ends, and ſmelling ſomewhat ſweete, the ſeede is ſmall and blackiſh, contained in ſmall hard huskes: the roote ſpreadeth many long ſtrings under the ground, and abideth many yeares.

4. *Muſcipula Salamantica major.* The greater *Spaniſh* Catchflie.

The greater *Spaniſh* Catchflie hath divers grayiſh greene leaves lying upon the ground next the roote, which are ſmall and ſo long at the bottome as if it were a footeſtalk, but broader toward the end and ſomewhat long withall, of a grayiſh greene colour, from whence riſe up divers round greene ſtalkes, a yard high, bearing ſuch like leaves at the joynts by couples up to the tops of them almoſt, but ſmaller where the branches beare many ſmall tufts of greeniſh flowers at ſeverall ſpaces round about them, and where in the heate of Summer there will be a viſcous or glutinous ſappe on the outſide, fit to make any ſmall light thing to ſticke to it: after the flowers are paſt, the ſeede ſheweth it ſelfe of a grayiſh colour, conteined in ſmall hard greeniſh huskes: the roote is white hard and long, abiding after ſeedetime, and ſpringing a freſh every yeare.

5. *Muſcipula Salamantica minor.* The ſmaller *Spaniſh* Catchflie.

The ſmaller *Spaniſh* Catchflie differeth ſo much in forme from all the other ſorts of wilde Campions, that it might ſeeme to be none of the family: but becauſe as *Cluſius* ſaith, the learned of *Salamanca* did call it *Seſamoides* as they did the former, which is moſt fit to be of the number of the wilde Campions, hee thought it never the leſſe not unfit to joyne them together, and ſo doe I, untill I may know a fitter place to ſet it: It beareth many thicke long greene leaves, like unto line or flax upon the ſlender ſtalkes, beſides thoſe that are at the foote of them, ſet thicke thereon one above another, but without any order or proportion; at the toppes whereof grow many ſpiked heads of ſmall flowers of a purpliſh greene colour at the firſt, which turne into whitiſh greene threds afterwards with foure round heads in the middle, wherein when they are paſt grow ſmall blackiſh ſeede: the roote is ſomewhat great and white, and not periſhing: *Cluſius* ſaith hee found another ſort hereof, with white flowers and woolly leaves.

Flore albo

6. *Lychnis ſylveſtris viſcoſa rubra anguſtifolia.* The red *Germane* Catchflie.

The red *Germane* Catchflie ſendeth forth from the roote divers long and narrow darke greene leaves, pointed at the ends, ſomewhat rough or rugged, and not fully ſmooth as many other ſorts are, which lye upon the ground, and from among them riſe up two or three, and ſometimes but one browne ſtalke, a yard high bearing two ſmall leaves at the joynts, which are much ſeparate one from another, and which will bee clammy like the other, in the hot Summer time: the flowers have no ſent and ſtand almoſt from the middle of the ſtalke upwards, on long branches divers ſet together, every one by it ſelfe, upon a ſmall footeſtalke, of a lively deepe red colour, almoſt like the ſingle red Roſe Campion, made of five round leaves, parted in the middle, with a paler red circle at the bottome, ſet in greene huskes, ſmaller at the bottome and larger at the head, wherein after the flowers are fallen, the ſeede groweth of a browniſh colour: the roote is ſomewhat thicke and blackiſh enduring many yeares.

7. *Lychnis*

7. *Lychnis viscosa flore albo Italica, sive Muscipula Italica alba.* Woolly *Italian* Catchflie.

This white *Italian* Catchflie sendeth forth a browne joynted stalke two foote high, branched therefrom in divers places, no lesse clammy towards the toppes then the others, set with two leaves a peece thereat, which are somewhat long, narrow and hairy, or as it were covered with a soft downe upon the greene and pointed at the ends; at the tops of the stalkes and branches stand many snow white flowers in long striped whitish huskes, consisting of five round pointed leaves, cut in at the ends to the middle of them, making every leafe seeme as if it were two, and in the midst of the flowers ten white threds, tipt with whitish pendents, five whereof appearing when the flowers doe open and the other five when they decay and twine themselves: after the flowers are past come grayish seede in hard huskes or heads like unto the other common sorts: the roote perisheth not, but abideth long.

6. *Lychnis viscosa rubra angustifolia.* The red *Germane* Catchflie.

8. *Muscipula altera purpurascens.* Browne *Italian* Catchflie.

This Catchflie likewise hath woolly leaves, set by couples on the reddish greene stalke, somewhat larger then the former *Italian* kind: the stalkes and branches that grow up higher and especially at the toppes are more reddish or browne, and as clammy as any of the other, from whence come forth divers darke browniish striped stalkes bearing many flowers, consisting of five narrow leaves, cut into the middle of a smoakie purplish colour on the outside, and white within, with five longer threds in the middle, thicke and purplish at the ends, and five other shorter with white tippes: when the flowers beginne to decay they twine themselves as the last doth, the heads and seede are like unto the last, and so is the roote likewise which endureth long.

9. *Muscipula Italica flore carneo.* Blush coloured Catchflie.

This blush *Muscipula* hath woolly stalkes and leaves set thereon at the joynts by couples as in the rest, where also toward the toppes on every side, at every place and joynt with the leaves commeth forth a woolly striped swolne huske, with purplish white or blush coloured flowers, of five leaves a peece, divided at the ends in the middle, with some threds therein also: the roote of this is small and perisheth the same yeare it beareth seede, which is usually the second or third after the sowing.

10. *Muscipula altera Lobelij.* The other Catchflie of *Lobel.*

The leaves of this Catchflie are somewhat broad round pointed and of a whitish greene colour, but not woolly or hairy, not much unlike the other *Muscipula* called *Ben rubrum* set forth as I said in my former booke, and the figure also here: the stalkes have two or three joynts with leaves at them, and are glutinous towards the tops, where the flowers stand in clusters many set together being very small, and of a yellowish greene colour.

The Place.

These have their places signified in their titles, where they grow except the third, which came among other seedes unto me from a friend, the originall place being not knowne, and therefore there needeth no more to be sayd thereof.

The Time.

They all flower in the Summer moneths, and some not untill winter, especially the last.

The Names.

These kinds of wild Campions are called *Muscipulæ, quia muscas capiunt,* because they catch flies, &c. and *Viscaria* and *Viscago* of *Viscum,* the clammines like Birdlime whereby the flies are caught. *Thalius* calleth some of them Ἐσκαυλλον which signifieth the same thing, and *Bauhinus Lychnis sylvestris viscosa.* The first is the *Lychnis sylvestris latifolia Auriculæ vrsifacie* of *Clusius*: the second is so called by *Alpinus lib. de plantis exoticis,* as it is in the title: the third wee usually call *Muscipula perennis:* the fourth and fift are called by *Clusius Sesamoides Salamanticum magnum & parvum,* the greater being called by *Camerarius Viscago major*: the sixt is the fourth *Lychnis sylvestris* of *Clusius*: the seventh eighth and ninth are the three sorts of *Lychnis sylvestris* that sprang with *Clusius* from the seede he received from *Italy*: the last is mentioned by *Lobel* by the name of *Muscipula altera flore muscoso,* which *Bauhinus* in my judgement doth much confound with the *Sesamoides magnum Salamanticum* of *Clusius,* making them to be both one, and yet as I sayd in the Chapter before, he maketh it also agree with the first *Lychnis sylvestris* of *Clusius* in his History, which is the fourth *Armerius* with *Donæus,* usually called with us *Ben-rubrum Monspelienſium,* which all know are farre differing one from another.

The Vertues.

There are no especiall properties allotted to these Plants, but may be referred to those of the other wild Campions, whereunto they are likest in face and outward appearance.

Chap. LXXVIII.

Lychnides minores & repentes. Small and creeping wilde Campions.

THe laſt kind of wilde Campions are theſe, which eyther lie downe and ſpread or creepe with their branches, whether they be greater or ſmaller, or elſe being ſmall ſtand upright.

1. *Ocimoides repens.* Creeping wilde Campion.

This creeping wilde Campion ſendeth forth divers ſlender weake trayling flexible branches, divided into others, ſet full of joynts, and two leaves alwayes at them which are ſomewhat long like unto Mirtle leaves, or as *Lobel* ſaith unto knotgraſſe, but larger, that is ſhorter and broader: at the toppes of the branches ſtand ſmall bluſh coloured flowers in hairy long greene huskes, like the common wilde Campion, but leſſer, conſiſting of five ſmall round pointed leaves, cut or dented in with ſome threds in the middle, the roote is ſmall and long, and diſperſeth ſome ſtrings and fibres under ground, abiding divers yeares.

2. *Ocimoides Lychnitis Columnæ ſive Lychnis incana repens.* Hoary creeping wilde Campion.

This hoary wilde Campion hath ſmall hoary leaves ſet by couples upon the trayling hairy branches, which are ſomewhat broad comming neare unto the leaves of Baſſill, and a little pointed at the ends, the flowers grow many together in hoary long huskes, like the wilde Campions.

3. *Lychnis marina repens alba.* The white Sea Campion.

This Sea Campion hath divers weake flexible branches, lying all about upon the ground (much divided into other ſmaller ones) two or three foote long, thicke ſet with ſmall long flat and whitiſh greene leaves: at the tops of every branch ſtandeth one ſhort, thicke, whitiſh greene huske, parted or dented at the toppe, out of which ſhooteth forth a ſmall long necked white flower, very like unto that of Spatling Poppie, and as white, made of five ſmall round pointed leaves, with ſome blackiſh threds in the middle: the ſeede that followeth is browne, conteined in ſuch like huskes as other wilde Campions have, the roote is ſlender and long, and abideth many yeares.

4. *Lychnis marina repens flore rubello.* Red flowred Sea Campion.

This red Sea Campion differeth not from the former in any thing but in the colour of the flower, which in this is of a fine delayed red colour as in the other it is white.

5. *Lychnis arvenſis minor Anglica.* The ſmall white field Campion.

The lower leaves of this our ſmall wilde Campion are ſmall and hairy, very like unto the ſmall Mouſeare, but thoſe that grow upon the ſlender ſmall ſtalke, which is ſometimes ſingle of it ſelfe, and ſometimes many from the roote, are not above a foote high, two alwayes being ſet together at a joynt, ſmaller then thoſe below, and ſpotted with white ſpots; from the boſome whereof, that is, betweene them and the ſtalke come forth two other leaves, much ſmaller then they, without any manifeſt taſte: the flowers are ſmall and white like unto the other wilde Campions, after which come ſmall long heads, with grayiſh ſeede in them: the roote is ſmall and white and periſheth every yeare.

6. *Lychnis ſylveſtris lanuginoſa minor.* The little *Spaniſh* wilde Campion.

This ſmall wilde Campion hath a ſmall ſlender upright ſtalke, about an hand breadth high, or little more with divers joynts, and two leaves at every of them which are hoary, ſomewhat long and narrow: the flowers ſtand ſingle for the moſt part, each comming forth at the joynts with the leafe, and ſome alſo at the toppes of the ſtalkes and branches ſet in ſmall long hoary huskes ſtriped, conſiſting of five ſmall bright red leaves, dented at the ends in two places ſo making three points: the roote is ſmall and dyeth after ſeede time.

7. *Lychnis ſylveſtris minima exiguo flore.* The ſmall flowred wilde Campion.

This wilde Campion riſeth up with a ſmall round browniſh ſtalke, not halfe a foote high, ſpreading from the joynts (where there are two ſmall narrow and pointed leaves, ſmaller then the laſt, otherwiſe not much unlike) very ſmall branches ſomewhat rough or hairy, on the top of every one whereof ſtandeth one purpliſh flower made of five leaves, ſo dented in at the end of every leafe, that it expreſſeth the forme of an hart; the ſeede conteined in the ſmall heads is like the other: the roote is ſmall and endureth not.

8. *Lychnis exilis rubra.* The very ſmall red wilde Campion.

This ſmall Plant might rather be accounted a kind of ſmall Pinke, if the head with ſeede did not gaineſay it. For it hath many ſmall graſſe-like leaves at the foote of the ſtalke, and at the joynts of them, which ſtand thicke together, two or more ſuch like leaves but ſmaller: the flowers ſtand at the toppes of the ſtalkes two or three together in ſlender long huskes, very like unto thoſe of that *Muſcipula* or Catchflie, that is called *Ben rubrum Monſpelienſia* of a reddiſh colour dented at the ends, the roote is very ſmall and long and taſteth not.

9. *Lychnis tenuifolia altera.* The leaſt wilde Campion.

There is ſmall difference in this from the laſt in the ſmalneſſe of the growing or leaves, or poſture of them, but that this hath ſeldome above two leaves at a joynt, the flowers chiefely diſtinguiſh them, which are as ſmall but growing from the upper joynts, and ſome at the top of the thred like ſtalkes, of a pale greene colour, and without any notch or dent at the end of the leaves: the ſeede and ſeede veſſells are ſmall and like the reſt: the roote is like a thred, like unto theſe two laſt, I here ſhew you three other ſmall Plants whoſe deſcriptions every eye may reade that ſeeth the figures.

Exiles 3. altere. Three other ſmall ones.

10. *Ocimoides muſcoſus Alpinus.* Small mountaine wilde Campion.

The roote of this ſmall Campion although ſmall, yet is wooddy and of a whitiſh colour, not growing deepe but ſpreading much under ground, and ſhooteth forth a number of heads of ſmall greene leaves very thicke ſet together in tufts, in that manner ſpreading much ground, and covering it like Moſſe; from the middle of each head whereof, riſeth up a ſmall bluſh coloured flower, out of a ſmall long huske, but ſtanding upon ſo ſhort a ſtalke above the leaves, that it is ſcarſe to be diſcerned, in each part very like unto the firſt creeping wilde Campion; the ſeede is ſmall and browne, it hath no great ſent to commend it, but onely the beauty of the verdure, and bluſh, ſo thicke intermixt like a wrought carpet to pleaſe the ſight.

The

1. *Ocimoides repens.*
Creeping wilde Campion.

3. 4. *Lychnis marina repens alba vel rubra.*
The white or red flowred Sea Campion.

6. *Lychnis sylvestris Lanuginosa minor.*
The lesser *Spanish* wilde Campion.

10. *Ocimoides muscosus Alpinus.*
Small mountaine wilde Campion.

The Place.

The firſt groweth on Mount *Baldus*, and in the ſhadowie hills and woods of *Provence*, and in other ſuch like places: the ſecond *Columna* ſaith he found in *Naples*: the third groweth by *Hurſt Caſtle* neare the Iſle of *Wight*, and in the ſayd Iſle alſo in many places by the Sea ſide: the fourth is found in ſome of thoſe places aforeſaid, as alſo about a mile from *Southampton*, in the ground of one Mr. *Gouch* a Divine: both of them chiefly in the South parts of this land, on the moſt ſtony bankes by the Sea ſide: the fift groweth in divers grounds by *Colchester* in *Eſſex*, and in a field called the Millfield, behind the houſe of Sr. *Thomas Lucees* neare *Colcheſter*: the ſixt as *Cluſius* ſaith he found no where elſe then on the hills neare *Salamanca* in *Spaine*: the ſeventh groweth at the foote of the hill that is by *Bontonet* neare unto *Momplier*, and in the borders of the fields neare *Forence*: the eighth and ninth in divers places of our owne Land: the laſt upon mount *Baldus*, as *Pona* ſaith, and by *Cluſius* his report upon the *Alpes* of *Auſtria*, and *Stiria* on the higheſt places of them.

The Time.

They all flower in the Summer Moneths of *Iune*, *Iuly* and *Auguſt*, ſome earlier or later then others, and their ſeede is ripe quickly after.

The Names.

The firſt is called *Ocimoides repens* by *Camerarius* and *Pona*, *Lobel* addeth *Poligoni folio Saponariæ flore*. *Geſner in hortis* calleth it *Ocimoides Alpinus*. *Bauhinus* taketh it to be the *Cneorum* of *Matthiolus*, but I thinke verily he is therein much miſtaken, for that as *Cluſius* ſaith, that *Cneorum* beareth a long white berry (a red ſaith *Myconus* in *Lugdunenſis hiſtoria folio* 1364.) ſomewhat like unto the berry of *Thymælea*, with a ſeede therein very like unto it alſo, which in part was the cauſe that *Cluſius* did referre it to the *Thymælea*, excepting the ſharpe taſte, and *Bauhinus* followeth him alſo in fol. 463. of his *Pinax*, making a Chapter peculiar of *Cneorum Matthioli*, which he there calleth *Thymælea affinis facie externa*; and if it be that, how can it be then this *Lychnis*; for this *Ocimoides* beareth a head or ſeede veſſell ſomewhat like unto the other wilde Campions, and ſeede therein like unto them alſo: but whether *Cneorum Matthioli* ſhould be either that of *Dioſcorides* or *Galen*, or of any of the two ſorts of *Theophraſtus* in his ſixt Booke and ſecond Chap. is much doubted of by divers, and what plants are the true is as much controverted. *Anguillara* and others thought the *Cneorum album* and *nigrum* of *Theophraſtus*, were *Lavendula* and *Roſmarinum*, our ordinary Lavender and Roſemary (as is ſayd before in both the Chapters of Lavender and Roſemary) whom *Matthiolus* contrarieth, ſhewing that neither of them can bee ſo as it isrthere declared: others thinke they might be referred to the *Chamælea* and *Thymælea* of *Dioſcorides*; but in theſe two there can be no diſtinction of white and blacke, being both of them greene, and neither of them whiter then others, and beſides they doe both flower in the ſpring, and not in the Autumne, as *Theophraſtus* ſaith his doe; notwithſtanding that the leaves of *Thymælea* by *Dioſcorides* was called *Cneorum*, and *Pliny* ſaith that *Thymælæa* was called of ſome in his time *Cneſtrum* and *Cneorum*. Now how neare *Matthiolus* his *Cneorum* commeth unto that of *Dioſcorides* and *Galen* is to bee ſhewed: it is certainely held that that of *Dioſcorides* and *Galen* doth much vary from thoſe of *Theophraſtus*, as *Matthiolus* ſaith in both his Epiſtles to *Crato*, in his third Booke of Epiſtles Fol. 134. and in his fourth Booke Fol. 172. and ſaith that becauſe the *Cneorum album* is ſweete, therefore according to *Pliny* in his 21. Book and ninth Chap. and twelfth Chap. it was reckoned among the ſweete herbes that were put into Garlands, which neither *Chamælea* or *Thymælæa* doe, but is as hee there ſaith called *Caſia* by *Higinus*, which it ſeemeth it was alſo by *Virgill* in divers places of his *Georgicks* and *Bucolicks*; as firſt in his *Bucolick Eclogues*, he ſheweth one of the *Naides* worke in making a Garland in theſe Verſes:

Tunc Caſia atque alijs intexens ſuavibus herbis,
Mollia luteola pingit vaccinia caltha.

And in the ſecond of his *Georgicks*,

Vix humiles apibus caſias roremque miniſtrat.

And in the fourth of the ſame,

Nec circum caſiæ virides & olentia latè
Serpylla, & graviter ſpirantes copia thymbræ
Floreat, irriguumque bibat violaria fontem.

All which doe plainely ſhew that *Caſia* was commonly accounted with them a ſweete herbe, uſually planted for Bees to feede on, as well as to put into Garlands; and not that *Caſſia* which is a tree like unto Cinamon, called of the Apothecaries *Caſſia lignea*, for which cauſe it is very probable that *Gaza* in tranſlating *Theophraſtus* Greeke copie into Latin, put *Caſia* for *Cneorum*, taking them to bee both one: for *Cneorum* as *Dioſcorides* and *Galen* ſay, was the leafe of that plant that bare the *Coccus Ginidius*, which by all the beſt moderne Herbariſts groweth upon *Thymælæa*, being the fruit thereof, which both in face and qualitie differ much in ſunder as is ſhewed before. Now how much it differeth from thoſe of *Theophraſtus*, reſteth to bee declared, that it cannot agree with his blacke *Cneorum*, needeth no further demonſtration then is ſhewed before: but that it commeth neare to his white moſt doe agree, yet ſome things therein are doubtfull, as firſt there is no ſhew therein, why it ſhould be called white, ſecondly the branches are not ſo pliant and ſtiffe that they may ſerve to binde things withall as ruſhes are: thirdly the roote is not very great; and laſtly it doth not flower after the Autumne ſolſtice, but in the Spring. Thus farre I have digreſſed from the firſt *Ocimoides*, being drawne on by *Cneorum*, whereunto as I ſayd *Bauhinus* referreth it, and calleth it *Lychnis vel Ocimoides repens montanum*, and ſaith alſo that it is the *Ocimoides Alpinum* of *Geſner in horto*, and the *Saponaria minor Dalechampij* in *Lugdunenſis*: the ſecond *Fabius Columna* calleth *Ocimoides Lychnitis*, and by *Bauhinus Lychnis incana repens*: the third is remembred by *Lobel* and *Lugdunenſis*, and *Tabermontanus* that follow him and called *Lychnis marina Anglica*, and *Lychnis maritima repens* by *Bauhinus*: the fourth is mentioned in *Gerards* Herball, taken but by report, and is not truely written of by any before this time, that I know of: the fift is not remembred alſo by any other before now: the ſixt is the ſixt *Lychnis ſylveſtris* of *Cluſius* called by *Lobel Lychnis ſylveſtris hirta minima*: the ſeventh is very like unto it, and called by *Bauhinus Lychnis ſylveſtris minima flore parvo*: the eighth and ninth are not ſpoken of by any other: the laſt is called *Muſcus floridus* by *Geſner*, and *Caryophyllus ſylveſtris* 9. or *pumilio Alpinus* by *Cluſius*,

and

and by *Pona Ocimoid s muſcoſus Alpinus*; by *Bauhinus Lychnis Alpina pumila folio graminoe, ſive Muſcus Alpinus Lychnidis flore.* Every one hath his Engliſh name in his title fit to diſtinguiſh them.

The Vertues.

All or moſt of theſe herbes are of later knowledge, ſo that there is but little ſayd of their vertues, yet by their taſte ſome of them being ſomewhat drying and aſtringent may be profitably applyed to ſtay the fluxes of blood and humors, and thereby alſo conduce to the healing of old and moyſt Vlcers or ſores: the Sea kinds taſte ſomewhat brackiſh, yet not unſavory, ſo that they are often eaten cold as a Sallet herbe, or ſtewed and ſo eaten.

CHAP. LXXIX.

Saponaria. Sopewort or Bruiſewort.

AS a ſupplement to the wilde Campions, I have ſome other ſorts of herbes to bring to your conſideration, which both for face or forme, and for uſe and properties are ſo like unto the former, that they might well be taken as *ſpecies* of the ſame *genus*.

1. *Saponaria vulgaris.* Common Sopewort or Bruiſewort.

Having ſhewed you in my former booke the double *Saponaria* and under it in a ſort deſcribed the ſingle or common kinde, it might ſeeme needeleſſe here againe to ſet it forth, which indeede I would not have done, but that being briefe as well in the deſcription as in the vertues in that place, I thought good here to enlarge my ſelfe and therefore to inſert the deſcription thereof as well as another ſort thereof with it. The roote creepeth under ground farre and neare, with many joynts therein, of a browne colour on the outſide, and yellowiſh within ſhooting forth in divers places many weake round ſtalkes, full of joynts, ſet with two leaves a peece at every one of them on the contrary ſide, which are ribbed ſomewhat like unto Plantane and faſhioned like the common field white Campion leaves, ſeldome having any branches from the ſide of the ſtalkes, but ſet with divers flowers at the toppe, ſtanding in long huskes like the wilde Campion, made of five leaves a peece, round at the ends, and a little dented in the middle, of a pale Roſe Colour almoſt white, ſometimes paler, and ſometimes of a deeper colour, of a reaſonable good ſent.

2. *Saponaria Anglica convoluto folio.* Hollow leafed Sopewort.

This kind of Sopewort, which is peculiar to our owne land, in the forme and manner of the running of the roote is very like unto the former, but much ſmaller ſending forth divers weake round ſtalkes, with fewer joynts then in the former, and at every one of them one leafe and ſeldome more, which eyther compaſſeth the ſtalke at the bottome as many of them doe, or being hollow the whole leafe like a pipe or trunke compaſſeth it before it open it ſelfe on the outſide, or ſometimes doth not open it ſelfe at all, and are ribled like the former, ſomewhat

1. *Saponaria vulgaris.*
Common Sopewort.

2. *Saponaria Anglica convoluto folio.*
Hollow leafed Sopewort.

broader and rounder at the ends: theſe ſtalkes have no branches at all, but from ſome of the upper joynts, and at the toppes ſtand three or foure flowers, upon ſlender footeſtalkes in long huskes, made of five leaves for the moſt part ſomewhat broader at the ends then the former, and uneven, and many times breaking the huskes wherein they ſtand, on the one ſide or other, of a pale white colour enclining to a bluſh, eſpecially on the ſides, of little or no ſent at all: wee never yet obſerved the ſeede or ſeede veſſells, being increaſed ſufficiently by the roote.

The Place.

The firſt groweth wilde in many low and wet grounds of this lands, by the brookes, and ſides of running waters, and is brought for the flowers ſake into many country gardens alſo, to ſerve to decke up their houſes, the other was firſt found and ſet forth by Mr. *Gerard* in his Herball, and hath not beene found to grow any where elſe then in that little Grove called the *Spinny* which is neare unto *Lichborrow* in *Northamptonſhire*.

The Time.

They both flower in *July*, and uſually not before, and ſo cotinue all *Auguſt* and part of *September*, before they will be quite ſpent.

The Names.

This Herbe is uſually called *Saponaria* becauſe it ſerveth in ſtead of Sope to waſh any thing withall; & therefore *Fuſchius* firſt of all other writers as I take it, ſet it forth for the στρούθιον *Struthium* of *Dioſcorides*, *Galen*, *Theophraſtus* and *Pliny*, which commeth from the Greeke word στρυφνίζειν which ſignifieth *Canas purgare, & candidas facere*, but quite differeth from it as you ſhall heare by and by; for although this as well as many others, may be called *Struthia*, of their ſcouring and clenſing quality, yet none of them have the right deſcription of *Struthium* (which of the Latines is called *Radicula*, and *Lanaria herba*, and by ſome others alſo transferred to this *Saponaria* but erroneouſly) and overpaſſed by *Dioſcorides* as too well knowne in his dayes, and therefore needed no deſcription, and but remembred onely by *Theophraſtus* in his ſixt Booke and third Chap. of his hiſtory of Plants, among thoſe herbes whoſe leaves are prickley. *Pliny* in his 19. Booke and third Chap. deſcribeth *Struthium* at large: his owne words I thinke fit to ſet downe and afterwards interpret them, that all may know what little care and judgement divers have ſhewed in referring the more obſcure Plants of the ancients, in not duly comparing and examining their Authors words and declarations. *At quæ vocatur Radicula* (ſaith *Pliny*) *lavandis demum lanis ſuccum habet: mirum quantum conferens candori mollitiæque. Æque naſcitur ſativa ubique, ſed ſponte præcipue in Aſia Syriaque, ſaxoſis & aſperis locis, trans Euphratem tamen laudatiſſima, caule ferulaceo, tenui, & ipſo cibis indigenarum expetito, & tingenti quicquid ſit cum quo decoquatur, folio Oleæ, Struthium Græci vocant: floret æſtate grato aſpectu verum ſine odore, ſpinoſa & caule lanuginoſo ſemen ei nullum, radix magna quæ conciditur ad quem dictum eſt uſum*: which may be thus Engliſhed, But that herbe which is called *Radicula*, hath a juice or ſappe therein fit to waſh clothes: it is wonderfull to ſee what whiteneſſe and ſmoothneſſe thereby it giveth unto them. The manured ſort groweth with many in divers places, but of it owne accord in *Aſia* and *Syria*, in rocky and rugged places; but the chiefeſt and moſt praiſe worthy groweth beyond *Euphrates*, having a ſmall ferulous ſtalke, which the inhabitants doe eate with their meats, and is apt to colour or dye any thing that ſhall be boyled with it, and hath the leafe of an Olive tree: the Greekes call it *Struthium*. It flowreth in Summer, and is pleaſant to behold but without any ſent, being prickly, and the ſtalke woolly: it beareth no ſeede, the roote is great and being cut in peeces ſerveth for the uſes aforeſayd. Thus farre *Pliny*. Now if you will compare the *Saponaria* with this deſcription, you ſhall finde that the *Saponaria*, hath no Olive like leafe, but rather like a Plantane, it hath no ferulous nor woolly ſtalke, but ſmooth and joynted, it hath no prickly leaves but ſmooth nor no great roote but ſmall and creeping; it wanteth neyther ſent nor ſeede, as *Pliny* ſaith *Struthium* doth: ſo that it is wonderfull that any ſhould make them both one, for one qualities ſake onely of ſcowring or clenſing; when ſo many delineations are abſolutely different: and therefore doth *Matthiolus* contrary *Fuchſius* plainely as alſo thoſe that took the *Lutea*, or *Luteola herba* to be *Struthium*, which he therefore called *Pſeudo Struthium*. Divers alſo in taking it to be *Struthium*, called it alſo *Condiſi* of the *Arabians*, which is thought to be the *Struthium* of the Greekes, and have applyed and uſed it for all thoſe purpoſes whereunto they have appropriated their *Condiſi* unto: but *Bellunenſis* giveth the deſcription of *Condiſi* in theſe words: It is the roote of a plant (that hath prickly leaves like a Thiſtle) of the thickneſſe of ones thumbe ſomewhat yellowiſh on the inſide and blacke without, ſharpe both in ſent and taſte (*Serapio* out of *Dioſcorides* ſaith) the roote is long and round, and of a quicke ſharpe taſte, which words are wanting as *Lugdunenſis* ſaith in the printed Latine copies) with the decoction thereof they uſe to clenſe both wooll and clothes; and the ſweete oyntment makers in *Damaſco*, doe put it into their confections that are made of honey, and boyled wine, which giveth them ſuch a whiteneſſe that they ſeeme as if they were made of Sugar, and Starch: with the roote cut into peeces, the *Syrians* uſe to waſh the filth out of their garments or ſhirts inſtead of Sope or Lye. I have beene ſomewhat tedious in declaring theſe things, that others might underſtand what *Struthium* and *Condiſi* are, and that neither *Saponaria* nor *Luteola* can be it, for there is no heate or ſharpeneſſe in eyther of them, beſides their differing forme: the firſt is generally called *Saponaria* by all writers except *Tragus* who calleth it *Viola agreſtis*, and *Fuſchius*, who as is ſayd called it *Struthium*: the other *Gerard* called *Gentiana concava*, and placed it next unto them, thinking it a *ſpecies* thereof, but it is plainely ſeene and knowne to agree with the *Saponaria*, both in rootes leaves, and flowers, and not with *Gentian* but in the bitterneſſe. It is uſually called in *Engliſh* Sopewort, and of ſome Bruiſewort: the countrey people in *Kent* and *Suſſex* call it Gill run by the ſtreet.

The Vertues.

The Country people in divers places doe uſe to bruiſe the leaves of Sopewort, and lay it to their fingers, hands or legges, when they are cut to heale them up againe. Some make great boaſt thereof, that it is diureticall to provoke urine, and thereby to expell gravell, and the ſtone in the reines or kidnies: and account it alſo as ſingular good to avoyd Hydropicall waters, thereby to cure the diſeaſe, but their practicke is not I thinke ſufficient autentike, upon their theory or ſpeculation, to inforce beleefe that it will clenſe the inward parts, as by experience it is found to doe the outward of womens greene and pewter veſſels: they no leſſe extoll it to performe an abſolute cure in *Lue Venerea*, then either *Sarſaparilla*, *Guajacum*, or *China* can doe; which how true it is let others judge, that have judgement upon true knowledge of the truth; for my ſelfe, I cannot be induced to beleeve the one halfe, untill more evident proofes doe convince me.

CHAP

CHAP. LXXX.

Trachelium ſive Cervicaria. Throatewort.

VNder the name of *Trachelium* (which is a kinde of *Campanula* or Bellflower) may all the reſt of the Bell-flowers be comprehended, whereof ſome I have already ſet forth in my former booke, but becauſe there are ſo many, I thinke fitteſt to diſtribute them into ſeverall Chapters, that ſo they may be the better expreſſed by me, and apprehended and retained by you, and diſtinguiſhed to all. In this Chapter I will onely mention the reſt of them that have rough or hayry leaves, and in the next thoſe that have ſmooth.

1. *Trachelium majus Belgarum.* Great Throatewort

This great Throatewort hath very tall and great hayrie ſtalkes and leaves of the faſhion of the other ſort, that I have ſet forth in my other booke, there called the greater *Canterbury* Bells, but greater than it, both in ſtalke and leafe, the flower is of a purpliſh blue colour, almoſt as large as thoſe of the *Coventry* bels, in all other things it agreeth with the other.

2. *Trachelium petræum majus globoſum.* The great globe rocke Throatewort.

The greater of the two rock Throateworts, riſeth up with browniſh or reddiſh ſtraked hayrie ſtalks, about two foote high, bearing thereon divers rough or hayrie darke greene leaves on the upper ſide, and paler underneath, ſet without order, and a little dented about the edges with ſome ſmaller leaves ſet at the joynts with them: at the toppes of the ſtalkes eſpecially, grow many flowers, cluſtring together in a round faſhion, and ſome at the upper joynts alſo with the leaves, but not ſo many, and ſome alſo under them at the lower joynts, but ſtill fewer and fewer, being all of them, of the forme of the former Throatewort, but of a white colour, and ſmaller than the ſmall, or ordinary ſort, and ending in five, ſixe, or ſometimes in ſeven points, having in the middle many yellowiſh threds, and one greater than the reſt, crooked at the end when it is biggeſt, and which becommeth biforked, and blunt as it ripeneth, the flowers abide long before they fall, but the ſeede hath not beene obſerved: the roote is ſomewhat great and wooddy, rugged on the outſide and reddiſh, but white within, and more aſtringent than any of the reſt.

3. *Trachelium petræum minus globoſum.* The leſſer globe like rocke Throatewort.

The leſſer of theſe Throateworts, hath the firſt leaves ſomewhat long and not dented on the edges but pointed, and after them riſe diverſe others that are round, and cut in on the edges, ſtanding on long footeſtalkes, an hand breadth long at the leaſt, ſomewhat like unto thoſe of *Cimbalaria Italica hederacea*, the Ivie like leafe, or *Italian Gondelo* but not ſo thicke, fuller of ribbes and veines, deeplier cut in on the edges, and of a darke greene colour, from which riſe divers naked or bare ſlender ſtalkes, about halfe a foote high, which uſually have one or

1. *Trachelium majus Belgarum.*
Great Throatwort.

2. *Trachelium majus petræum globoſum.*
The greater globe rocke Throatwort.

two

3. *Trachelium petræum minus globosum.*
The lesser Globe-like Throatwort.

6. *Trachelium saxatile spicatum.*
The rocke spiked Throatwort.

7. *Trachelium spicatum tenuifolium.*
Thinne leafed Throatwort with spiked heads.

Trachelium minus.
The small Throatwort or *Canterbury* Bells.

two leaves about the middle of them, with little or no ſtalke at all to them, ſomewhat deepelyer dented about the edges, at the toppes of theſe ſtalkes ſtand foure or five long and narrow greene leaves like unto thoſe that are about the middle of the ſtalkes, but leſſer, narrower and more jagged compaſſing them at the heads, and from the middle of them ſtart forth divers ſmall flowers, ſet in a tuft together, of a darke blewiſh purple colour, with very ſhort footeſtalkes under them, and are faſhioned ſomewhat like a bigge bellyed bottle, with a ſmall long necke, opening at the brimmes into five points, ſomewhat deepely cut downe, with divers threds in the middle one being bigger and longer then all the reſt, iſſuing a good way beyond the necke which in the ripening becommeth the ſeede veſſell, biforked like the other: the roote is very rugged whitiſh and wooddy.

4. *Trachelium montanum majus.* The greater mountaine Throatwort.

The greater mountaine Throatwort ſendeth forth from a long blackiſh roote, thicke at the head and growing ſmaller downewards, with many ſmall fibres ſet thereat, and ſome bigger, a number of long and narrow leaves, ſomewhat like thoſe of Alkanet, ſet at the bottome of the ſlender round reddiſh ſtalke, which is about a foote or more high, with very few leaves thereon, at the toppes whereof grow a few long flowers, ſomewhat like unto the ordinary ſort, of a pale purpliſh colour, with a long Peſtell in the middle.

5. *Trachelium montanum Tragopogi folijs.* Narrow leafed Throatwort.

This Throatwort hath ſundry narrow long leaves lying next the ground, ſomewhat reſembling thoſe of Goates beard, the flowers at the toppes of the ſtalke are Bellfaſhion and ſomewhat ſmall, of a bluſh colour the ſeede that followeth is ſmall like the reſt.

6. *Trachelium ſaxatile ſpicatum.* The rocke ſpiked Throatwort.

This ſpiked Throatwort ſendeth forth from a white great roote full of bunnches or knots on the outſide, as it doth grow old, and ſpreading under ground many branches with fibres thereat, ſundry round and crooked hoary white ſtalkes, of an unequall height, ſome being a foote and ſome leſſe high, with broad leaves ſet thereon without order, moſt uſually but one at a joynt, but ſometimes two unevenly dented about the edges, ſomewhat like the leaves of *Doronicum*, or of that herbe is called by ſome *Palmonaria Gallorum*, by others *Piloſella major*, and *Chondrilla aurea*, and we in *Engliſh* as I have ſhewed you in my former booke Grim the collier but hoary, eſpecially underneath: from the middle of the ſtalkes upwards come forth ſome flowers at the joynts with the leaves, but eſpecially at the toppes many together ſpike faſhion, one above another, which are ſmall and of a blewiſh purple colour, but like in forme unto the ordinary Rampions, or Throatwort: after which come ſuch like ſeede veſſells and browne ſeed in them as is in the ſmaller Throatwort: this as the reſt giveth milke both ſtalkes and rootes, which is no leſſe pleaſant and edible then the reſt, and endureth many yeares, although the ſtalkes dye downe every yeare.

10. *Trachelium folijs Echij.*
Wilde Bugloſſe leafed Throatwort.

7. *Trachelium ſpicatum tenuifolium.* Thinne leafed Throatwort with ſpiked heads.

This thinne leafed Throatwort hath many long and narrow hairy greene leaves, ſomewhat like unto thoſe of wilde Baſſill, but much ſmaller, betweene which riſeth up a ſtrong round greene ſtalke, about a foote high or more, ſomewhat ſtraked, and of the bigneſſe of a finger, ſet with narrower leaves and longer, from the bottome to the middle of the ſtalke and from thence up to the toppe come forth ſmall whitiſh coloured flowers, like the others, ſtanding at the joynts with the leaves, ending in a long ſpike of flowers and leaves, ſet thicke together very orderly: after the flowers are paſt commeth ſmall heads, conteining very ſmall browniſh ſeede: the roote is thicke and white, as bigge as ones finger, and rugged on the outſide, with ſome bigger fibres ſet thereat.

8. *Trachelium umbelliferum cærulium.* Vmbelliferous blew Throatwort.

This Throatwort groweth with a number of ſmall fibres ſet at the roote, from whence riſeth up a ſtalke about two foote high, having a few hard rough greene, and ſomewhat long leaves ſet one above another, very like unto the ordinary ſort, and dented about the edges in the ſame manner: from the middle of the ſtalke upward at the joynts it ſendeth forth branches ſet with ſuch like leaves as grow below, but leſſer and leſſer, every branch being bare or naked of leaves for a little ſpace, next under the toppe, where there ſtand two ſmall narrow leaves, and from thence riſe many ſmall perfit blew flowers, ſet upon little ſhort footeſtalkes in manner of an umbell or tuft, all of them in a manner ſtanding to an equall height, ſomewhat like to mountaine Spikenard, the heads and ſeede are like the reſt: all the whole plant giveth milke, and is of an aſtringent and ſharpe taſte, but is very impatient of cold and therefore muſt have ſome extraordinary care beſtowed on it in theſe colder countries, to preſerve it in the winter.

9. *Trachelium pumilum Alpinum.* Small Mountaine Throatewort.

This ſmall Throatewort hath many leaves riſing from the roote, like the common ſmall ſort (whoſe figure I here give the deſcription being extant in my former booke) every one ſtanding upon a long foote ſtalke, among which riſeth up a round ſtalke diverſely branched, having all the leaves that grow thereon, narrower and longer pointed than thoſe below, and without any ſtalke to compaſſe the branches at their lower ends; at the toppe of

every

every one ſtandeth a reaſonable large flower in faſhion like the ordinary, ending in five points, but of a pale blewiſh almoſt aſhcolour in ſome, but of a deeper blewiſh purple colour in others: after the flowers are paſt the heads wherein the ſmall whitiſh ſeede lyeth, turne downewards when they are ripe, and are three ſquare: the roote is white and great, for the proportion of the plant, having divers heads at the toppe thereof, where the leaves ſhoote forth: the whole plant hath a ſoft doune ſomewhat whitiſh upon it, and giveth milke as all the reſt doe.

10. *Trachelium foliis Echii.* Wild Bugloſſe leafed Throatewort.

The lower leaves of this Throatewort or Bell-flower, are many, long, very rough and narrow, lying upon the ground, like unto Vipers Bugloſſe but broader and ſhorter, whoſe ſtalke that riſeth up amongſt them, is about a foote high, round and rough alſo, ſet with few leaves but ſmaller, at the toppe whereof ſtand five or ſixe blue flowers Bell-faſhion, upon ſhort footeſtalkes hanging downe their heads, whoſe brimmes as alſo the huskes wherein the flowers ſtand, have ſome hayrie douninеſſe upon them. There is a leſſer of this ſort as *Bauhinus* *Minor.* ſaith, which hath hayrie ſhorter leaves and leſſer flowers, found on the hils among the *Switſers*.

11. *Trachelium ſerotinum, ſive Viola Calathiana forte Gerardi.* The late flowring Throatewort.

This late flowring Throatewort hath the lower leaves very like for forme unto the *Campanula Pyramidalis* or ſteeple Bell-flower but ſofter in handling, the ſtalkes riſe a yard high being ſoft or almoſt woolly like the leaves, & divided into ſome branches at the tops, bearing many Bell faſhioned flowers like the ordinary greater ſort, but ſmaller and of a pale blewiſh or purpliſh aſh colour, which by reaſon of their late flowring gave me no ſeede any yeare, the roote is thicke and buſhie.

12. *Rapunculus Scabioſæ capitulo cæruleo.* Rampions with Scabious like heads.

I was long in ſuſpence with my ſelfe and unreſolved, whether I ſhould ſet this plant in this place or no; for finding good authors to ſet it forth as a Scabious, and *Columna* onely and *Bauhinus* that followeth him, to diſſent from them and make it a *Rapuntium*, firſt, becauſe it giveth milke which no Scabious doth, and then the ſeede being altogether Rampion like, wherein I would judge of a plant moſt materially, I could not upon theſe reaſons fitly joyne it with the reſt of the Scabious, but place it here according to the title with this deſcription. It hath very many creſted ſtalkes, browniſh at the bottome, riſing up to be a foote high, from a long white living roote, giving milke with many ſmall narrow, and ſomewhat long leaves, whoſe edges are ſomewhat dented, or rather waved and writhed, than cut in, ſtanding thick thereon, without order on all ſides, and covered with a ſmall ſoft doune or hayrineſſe, unto the toppes almoſt, yet leaving a good ſpace bare: the flowers ſtand in a round head, made of five narrow ſhort blue leaves, the middle part formed into white ſtarres and ſtanding in greene huskes cut into ſixe or ſeven points, and a long pointell in the middle, which flowers are long at the firſt, and riſe by degrees, ſome falling away when others are beginning to open themſelves; all of them when they are paſt, and fallen, leave the greene huske ſtanding like a ſtarre, in the middle whereof groweth a ſmall head, conteining ſuch like ſmall browne ſeede as the others have.

13. *Campanula Drabæ minoris folijs.* Bellflowers with ſmall dented leaves.

The leaves of this Bellflower are rough or hairy, greene and ſmall, about an inch long, and halfe an inch broad, ſnipt about the edges, and pointed at the ends, ſtanding on each ſide of the hairy ſtalkes that are ſcarſe a foote high, without footeſtalkes: the flowers are but few, of a meane ſiſe, formed like Bellflowers, but ending in ſix corners or points, of a blewiſh colour ſet upon long footeſtalkes: the roote is white and long like the Rampions.

14. *Viola Mariana peregrina.* The *Syrian* Coventry Bells.

Vnto theſe kind of Plants may very well ſort the Coventry Bells, as being neareſt unto them, and therefore I thought it not amiſſe to joyne this unto them, in this Chapter, ſet forth by divers, after *Ranwolfius* had firſt declared it, as he found it at the foote of Mount *Libanus* in *Syria*, in the ſhadowy woods. It hath ſaith he many long and narrow leaves, riſing from the roote which is ſomewhat great and long, very like thoſe of the ſmall Ribbewort Plantaine, but more cut in unevenly on the edges, and hairy alſo, but upon the ſtalkes thoſe leaves are ſmaller, and not cut in at all, bearing the flowers at the joynts with them up to the toppes, which are larger and more open then the ordinary ſort, and parted into ſeaven or eight corners of a pale purpliſh colour: the ſeede he could not obſerve, being not the time of ripening:

15. *Trachelium ſubrotundis folijs.* Round leafed Throatwort.

From a ſmall creeping roote, a ſtalke of halfe a foote high being a little hairy riſeth up, with a few ſomewhat round leaves ſet thereon, hairy or rough alſo, of about two inches broad, and as long, and little dented about the edges, at the toppe whereof ſtand a few ſmall blew pendulous flowers like unto the others.

The Place.

Theſe grow naturally in divers places, as ſome in *Candy*, ſome upon Mount *Baldus*, and others of the *Alpes*, in *Germany*, in *Italy* alſo and in *Naples*, as *Cluſius* and *Columna* hath ſet it downe, onely the laſt ſave one in *Syria* as is aforeſayd, and the laſt was ſent *Bauhinus* from *Helmſtade*.

The Time.

They all flower in the Summer Moneths of *Iune* and *Iuly*, but yet ſome of them flower not untill all the reſt are paſt, and ſcarſe perfect their ſeede, but are encreaſed by their roote.

The Names.

It is called τράχηλον, *Trachelium* both in Greeke and Latin, or *Cervicaria*, for that it helpeth the ſores of the neck and throate, either inward or outward; it is alſo called *Vvularia*, becauſe it helpeth the *Vvula* the palate of the mouth (which hath the diminitive from *Uva*) for the likeneſſe unto a grape, when it is ſwollen and fallen downe, others call them *Campanulæ* of the likeneſſe of the flowers unto Bells, and therefore called Bellflowers; by which generall name not onely theſe but the others in the next Chapter, and many other plants are alſo called. Some alſo call them, *Rapi ſylveſtris genus*, but unproperly, and *Rapunculus* or *Rapuntium*, Rampions, becauſe they are like unto Rampions, and many of them edible as they are. *Cæſalpinus* onely as I take it, thought the great ordinry ſort to be *Archangelica*: the *French* call them *Gantelettes* and *Gans de noſtre Dame*, the *Germanes* and *Dutch Halzkruit*, and we in *Engliſh Canterbury* Bells, and Throatwort, of ſome Haskewort: the firſt here ſet forth is that ſort that *Lobel* calleth *Trachelium majus Belgarum*, and *Bauhinus* to vary the name *Campanula maxima folijs latiſſimis*: the ſecond and third is ſet forth by *Pona*, in the deſcription of Mount *Baldus*; the greater

whereof

whereof *Bauhinus* calleth, *Campanula Alpina ſphærecophalos* and the leſſer *Rapunculus Alpinus corniculatus*, which in his *Phytopinax*, and *Matthiolus* he called *Rapunculus Alpinus ſpicato ſimilis*; but having obtained a more exact knowledge thereof from *Pona*, he altered the title and gave both the deſcription and figure more plainely: the fonrth is called *Trachelium montanum* of *Lugdunenſis*, which *Bauhinus* calleth *Campanula folijs Anchuſæ floribus oblongis*: the fifth *Columna* calleth *Trachelium montanum*, and *Cluſius Trachelium Tragopogi folijs*; but *Bauhinus* turning all the *Tracheliums* almoſt to *Campanulas* calleth it *Campanula Alpina Tragopogi folijs*: the ſixt *Cluſius* ſetteth forth in his *Curæpoſteriores*, having received it from *Gregorius de Reggio* a Chapuchine Fryer of *Placentia* in *Italy*, by the name of *Pyramidalis villoſa ſaxatilis latifolia*; and *Cluſius* upon comparing it with others of the ſame kind, ſaith it may be called either *Rapunculus ſaxatilis montanus Doronici foliis*, or *Rapunculus montanus Pulmonariæ Gallorum folio*, and *Trachelii flore*. *Bauhinus* diverſifieth it to *Trachelium ſaxatile foliis Pulmonariæ Gallorum*: the ſeaventh *Cluſius* calleth *Trachelium* Διφυες, and *Thalius* in *Hercynia ſylva Cervicaria major tennifolia*. *Lugdunenſis* ſetteth it forth by the name of *Echium montanum Dalechampii*, and ſaith ſome called it *Alopecures montana*, but as *Cluſius* there ſaith, that though the leaves bee like unto *Echium*, yet ſo are not the flowers, ſeede, nor ſeede veſſells, and therefore cannot ſo properly be referred unto *Echium* as to *Trachelium*. *Bauhinus* calleth it *Campanula alia foliis Echii*, in the Chapter of *Trachelium*, and in the Chapter of *Echium* hee calleth it *Echium Alpinum luteum*, he referreth it likewiſe to this *Trachelium Thyrſoides*, of *Cluſius*. *Lugdunenſis* figure of *Echium montanum Cluſius* alloweth of to be his *Trachelium Thyrſoides*, but it cannot bee *Echium luteum* alſo, as any one may eaſily finde and know; but this muſt be accounted but one of his ſlippes of memory (for his firſt *Campanula Echii foliis*, and likely to be the figure of *Lugdunenſis* his *Trachelium montanum* indeede) and yet he ſaith it is not the ſame, but ſaith in his *Prodromus* he giveth the figure thereof becauſe *Cluſius* gave none, and yet his toppe of flowers doth not carry that ſhew of a thirſus or buſh as *Cluſius* ſaith his hath. The eighth *Pona* onely in his *Italian* deſcription of Mount *Baldus*, maketh mention of by the ſame name is in the title, having received it from Signor *Contarini*, a *Maginfico* of *Venice*, brought to him from *Candy*, as it is thought; which *Bauhinus* calleth *Cervicaria Valeriamoides cærulea*: the ninth *Cluſius* calleth *Trachelium pumilum Alpinum*, and *Bauhinus Campanula Alpina pumila lanuginoſa*: the tenth is called by *Bauhinus Campanula foliis Echii floribus villoſis* the eleventh *Gerard* calleth *Viola Calathiana*, the true Calathian Violet, upon what good ground I know not; for all Authors that have written of it ſince *Pliny* his time, who firſt gave the name have referred it to one of the Autumne *Gentians* (and himſelfe doth ſo likewiſe among the *Gentians*) except *Dalechampius* who tooke the *Digitalis lutea* to be it; yet maketh the ſame *Gentian* or *Gentianella æſtiva* to be it alſo, calling it *Thylacitis minor*, but I thinke he would not ſo have written, ſeeing himſelfe both knew and ſet it downe for a Throatwort, had he not herein beene led by his owne or ſome others willfull judgement, as it is moſt probable. I have as you ſee given it another title, moſt anſwerable in my judgement thereunto, and the deſcription moſt proper as it grew with me, the colour of whoſe flower I never ſaw, other then a pale blewiſh or purpliſh aſhcolour, and never any bright purple as he ſaith it is: the twelfth as I ſayd divers did take to be a ſmall or ſheepes Scabions, as *Geſner*, *Dodonæus Camerarius*, and *Lobel*, but *Columna* conteſting there againſt ſheweth by thoſe properties before ſpoken of, that it cannot be any ſort of Scabious but a *Rapuntium*, and calleth it *Rapuntium montanum capitatum leptophyllon*, and *Bauhinus* as it is in the title: the thirteenth *Bauhinus* onely mentioneth in his *Pinax* and *Prodromus* by the ſame name that I doe, *Rauwolfius* in his journall remembreth, and calleth *Medium Dioſcoridis*, and *Mindium Rhaſis*, and from him *Lugdunenſis* and *Camerarius* upon *Matthiolus* ſo call it. *Bauhinus* calleth it *Viola Mariana laciniatis foliis peregrina*. The laſt *Bauhinus* onely mentioneth in his *Prodromus* and *Pinax*.

The Vertues.

Although the rootes of many of theſe be ſweete in taſte, and therefore eaten in Sallets, eyther raw or ſtewed as both the greater and ſmaller ordinary ſorts of Rampions, ſet forth in the next Chapter, yet ſome of them here deſcribed as well as the greater ſorts, ſet forth in my former booke, are not ſo pleaſant but rather more aſtringent; by which qualitie they are found to be effectuall, not onely in all Vlcers of the mouth or throat, to gargle and waſh them, or for the *Vvula* or the palate of the mouth, when it is ſwollen and fallen downe; but for all other ſores, whether in the ſecret parts of man or woman, to be uſed in decoction with honey, wine and allome, or in any other part of the body; for by the faculty of drying and binding, they are very profitable for old ſores, to reſtraine the moyſt and ſharpe humours which fret the place and keepe them from healing, and for greene wounds and cuts, to cloſe up the lippes of them ſpeedily.

CHAP. LXXXI.

Rapunculi ſive Campanulæ glabræ. Rampions or wild Bellflowers.

AS in the former Chapter I ſhewed you thoſe ſorts of Bell-flowers, that had hoary, rough, or hayrie leaves, which as I ſayd are uſually called *Trachelia*, and *Cervicariæ*: ſo the other whoſe leaves are ſmooth and not hayrie or very little, are either called *Rapunculi Campions*, ſome being of old nurſed up in Gardens, for dayly uſe and to be neere at hand, or growing wilde, and onely uſed as they may bee found, or *Campanulæ* Bell-flowers, being like unto them in ſome things although that quality of bitterneſſe and healing bee wanting yet not to be diſjoyned.

1. *Rapunculus eſculus vulgaris.* Garden Rampions.

The Rampions that are uſually kept in gardens, are accounted a leſſer kinde than many of the others, that grow wilde and lying upon the ground, with divers ſmall and long round pointed pale greene leaves, before it runne up to the ſtalkes, which ſpread divers ſuch leaves thereon, but ſmaller to the toppe, where breake forth, ſundry ſmall pale purpliſh flowers, ending in five points like unto the former Throateworts, but much ſmaller, having alſo ſuch like heads, with ſmall browniſh ſeede therein: the roote is ſmall and white, and giveth milke being broken, as all the reſt of the plant doth; ſhooting two or three branches almoſt of an equall bigneſſe, which

is

1. *Rapunculus esculentus vulgaris.*
Garden Rampions.

2. *Rapunculus spicatus Alopecuroides.*
Long Foxetaile Rampions.

is ſweete in taſte, and therefore much uſed to be eaten.

2. *Rapunculus ſpicatus Alopecuroides.* Long Foxtaile Rampions.

The lower leaves of this *Rampion* are ſomewhat broad and round, yet ending in a point, dented about the edges, of a darke greene colour, in ſome places ſpotted with blacke ſpots, and ſtanding upon ſmall long foote-ſtalkes, but thoſe that grow upon the ſtalkes are ſomewhat longer and narrower, yet but ſparingly ſet here and there, leaving the toppe bare, where ſtandeth a ſmall ſpiked head or buſh of flowers, ſeeming like a Foxetaile whereof it tooke the name; at the firſt of a darke greeniſh colour, for ſo are the huskes of the flowers which breake out of them, being long and ſmall, like unto hornes, bigger below and ſmaller above, ending in foure and ſometimes in five points, of a blewiſh purple colour, in ſome paler in others deeper, and in ſome of a white colour, which being paſt there appeare in their places, ſmall round heads, a little cornered, with browniſh ſeede therein: the roote is white greater than the former, but as full of milke, and as ſweete and fit to be eaten as it, eſpecially when it is boyled, and after ſtewed with butter, &c.

3. *Rapunculus Alopecuroides orbicularis.* Round Foxtaile Rampions.

This kinde of Rampion differeth little in ſhew, from the rocke Throateworts, deſcribed in the Chapter before, but that the roote hereof is more full of milke, tenderer and ſmaller, not ſo hard or wooddy; the round leaves at the bottome are pointed and ſmooth, not haytie or hoary: the ſtalke a foote high or more, ſomewhat creſted having narrower and longer leaves on them than the lower, and ſixe or ſeven ſtanding together, at the toppe, under the ſpiked but round head of flowers, which are long and crooked, like unto thoſe of the rocke Throateworts, with five pointed ends, of a deepe purple colour in ſome, and white in others, and ſome yellow threds in the middle, the heads and ſeede are like the other Rampions.

4. *Rapunculus ſylveſtris umbellatus trium ſpecierum.* Buſh headed Rampions of three ſorts.

The three differences in theſe Rampions are that the one having ſomewhat broade and long leaves, little or nothing dented about the edges, and ſtanding one above another, upon the ſlender low ſtalkes, beare at the toppes ſmall open flowers, like unto the garden Rampions, but of a bluer colour, many ſet together in a buſh: another groweth higher, but hath narrower leaves and more dented, and flowers at the toppes ſtanding thicke together, but much ſmaller than the former, of a blewiſh colour alſo: the third is the leaſt of all, having lower ſtalkes and narrower leaves thereon than any, being almoſt like graſſe; the flowers likewiſe be little crooked hornes, pointed at the end, and of a pale blewiſh colour.

5. *Petromarula Cretica ſive Rapunculus Creticus.* Candy Rampions.

The firſt leaves that ſpring up from the ſeede of theſe Rampions, are round like unto Violet leaves, little or nothing dented about the edges, which ſo abide the firſt yeare, but thoſe that riſe afterward with the ſtalkes are much different from them, being much cut in and deeper into ſeverall parts, ſet on both ſides of the middle ribbe, the end being longeſt, all of them dented, of a darke greene colour on the upper ſide, and reddiſh oftentimes underneath; from among which riſe up diverſe creſted ſtalkes, two or three foote high, bearing ſuch like leaves

on

4. *Rapunculus sylvestris umbellatus trium specierum.* Bushheaded Rampions of three sorts.

5. *Petromarula Cretica sive Rapunculus Creticus.* Candy Rampions.

on them as below, but smaller from the middle of them to the toppes, stored abundantly with many reddish small purple flowers, and sometimes white, one above another in a long spike, which are very like unto Rampions, but somewhat longer, more divided in at the corners, and each part turning it selfe a little backe againe: after which come very small browniſh seede in heads, both of them like unto the other Rampions: the roote is great and white, parted into many branches, giving milke as the leaves and stalkes also doe, and abideth many yeares, although the stalkes and leaves perish every yeare, fresh springing up before winter againe: this is somewhat tender, and requireth to be alittle defended and preserved in the winter with us.

6. *Rapunculus sive Campanula Pyramidalis minor.* The lesser steeple Bell-flower.

This small Rampion or Bell-flower, call it which you will, hath from a small long white almost transparent roote, like unto that of the smaller garden Rampions, and long abiding, many long and somewhat broade leaves a little dented about the edges, set on each side of the single round stalke, rising about a yard high or more, broad bushing with leaves below, and smaller upwards bearing at the toppe a spiked head or bush with small Bell-like flowers, one above another, smaller below than above, of a fine delayed blewish colour, and a little pointed at the edges, with a long stile or pointell, growing out of the middle of every one, and smelling pretty well: the head and seede are like the other Peach leafed Bell-flowers. *Alpinus* suspected some venemous quality to be in this roote, upon the clammie taste therein, and doubted whether it might not be the *Aconitum folio Intubaceo* of *Theophrastus*, mentioned in his 9. booke, and 14. chap.

7. *Rapunculus nemorosus.* Wood Rampions.

The wood Rampion hath the loweſt leaves somewhat long and dented about the edges, yet not so long as those that come after them, which are very long and dented also, standing upon short stalkes with some smaller ones at the joynts with them, the flowers are like the other Rampions, of a pale watchet colour: the roote hereof is white and long, but not so tender as the other.

8. *Rapunculus nemorosus magno flore.* Wood Rampions with great flowers.

The lower leaves of this Wood Rampion are small, somewhat long and round at the ends: the other that follow and grow after them upon the stalkes, are narrower and longer and pointed also, the flowers are longer then others, of a duskie purpliſh colour, with purple veines in them, many standing together like unto the ordinary Rampions and of the same fashion with five points, of a deeper colour then the flower: the roote is somewhat thicke and of a whitish colour enclining to red, full of milke, being sweete and as fit to be eaten, and more desired where it is naturall then any other.

9. *Campanula Alpina latifolia pullo flore.* Sullen broad leafed Bell flower.

This little Bellflower hath a very small slender stalke, scarse an handbreadth high, set to the middle on both sides thereof, with small broad leaves, about an inch broad, and somewhat round withall; slightly dented about the edges, of a pale greene colour, and bare without leaves from the middle to the toppe, where usually stan-

6. 17. *Campanula Pyramidalis minor & Rapunculus petreus.*
Rocke Rampions, and the leſſer Steeple Bell-flower.

7. *Rapunculus nemoroſus.*
Wood Rampions.

deth but one flower, of a meane ſize, that is neither ſo great as many others of the following Bellflowers are, nor yet ſo ſmall as the littleneſſe of the plant might ſeeme to promiſe, of a ſullen darke purpliſh colour: the ſeede and roote are anſwerable to the Peach leafed Bellflower, which as I ſayd is extant in my former booke, and the figure thereof here exhibited.

10. *Campanula rotundifolia minima.* The leaſt broad leafed Bellflower.

This little plant hath divers leaves riſing from a ſmall, long, white, threddy roote, which are ſomewhat broad and round, a little dented and hard, each ſet on a ſmall footeſtalke, among which riſe up two or three ſlender ſmall reddiſh ſtalkes, not an handbreadth high, for the moſt part without any leaves upon them, at the toppes whereof grow uſually but one ſmall blewiſh flower, faſhioned like the other blew Bellflowers, ending in five or ſix corners with a pointell in the middle: the ſeede is ſmall like the reſt.

11. *Campanula minor ſylveſtris rotundifolia.* Wilde field Bellflowers.

The lower leaves of this kind of Bellflower, that lye upon the ground are alwayes round and ſmall, almoſt like unto a Violet leafe, but rounder, ſnipped or dented, from whence riſe divers weake ſlender ſtalkes, about two foote high, ſet from the bottomes to the toppes, with many very ſmall long and narrow leaves, where the flowers ſtand upon ſeverall ſmall long ſtalkes, very like in faſhion and bigneſſe, unto the ſmall Garden Rampions, but of a perfect blew colour, and ſometimes white, as hath beene obſerved in ſome places, yet very ſeldome: the ſmall ſeede followeth in ſmall heads like thoſe of the Rampions; the roote is ſmall and threddy.

12. *Campanula minima ſylveſtris.* Small wilde Bellflowers.

This Bellflower differeth little from the laſt, but in the ſlender ſtalkes, which having very few leaves thereon or none at all, are not ſtored with more flowers on them uſually then one, but of as perfect a blew or white colour as the former, and almoſt as large.

13. *Campanula linifolia cærulea.* Flax leafed Bellflower.

All the leaves of this Bellflower, as well the loweſt as thoſe upon the ſlender weake ſtalkes, ſcarſe a foote high or able to ſuſtaine themſelves, are ſmall, narrow and long like unto Line or Flax; the flowers are of a pale blewiſh purple colour, like in forme unto the other of the ſmall Bellflowers, and ſo are both ſeeds and roots.

14. *Campanula lutea linifolia.* Small yellow Bellflowers.

This is alſo in moſt things like the laſt, ſaving that the lower leaves are a little larger, yet long, and ſome of them a little dented about the edges: in the forme of the flowers or manner of growing this differeth not, but in the colour, which is of a pale yellow.

15. *Campanula Serpilli folia.* Time leafed Bellflowers.

This ſmall Bellflower hath many ſlender weake browniſh branches, riſing from a ſmall threddy roote, which creepe and ſhoote forth rootes as they lye upon the ground, divided into other ſmaller branches, very like unto Wilde Time, or Mother of Time, having many ſmall leaves of a pale greene colour underneath, ſomewhat round, ſet by couples one againſt another, along the middle ribbe, ſome of them being greater, like the ſmall purple Money wort, and others like the wilde Time but dented: the flowers grow at the ends of the branches, and ſometimes from the joynts with the leaves, ſtanding upon ſlender ſhort foote ſtalkes, ſometimes two together,

hanging

Campanula Persici folia.
Peach leafed Bell flower.

11. *Campanula minor sylvestris rotundifolia.*
Wilde field Bell flower.

14. *Campanula lutea linifolia.*
Small yellow Bell flower.

15. *Campanula Serpillifolia.*
Tyme leafed Bell flower.

hanging downe their head, like in forme and bigneſſe unto theſe laſt Bell-flowers, but of a reddiſh purple colour; the whole Plant doth ſo reſemble wild Time, that but the flowers onely can or doe diſtinguiſh them.

16. *Campanula Cymbalariæ foliis.* Ivie leafed Bell-flower.

The ſtalkes of this Bell-flower riſe up to be ſcarſe halfe a foote high, yet leane downewards upon what ſtandeth next it, and brancheth forth from the bottome almoſt, ſet very ſparingly and without order, with round and cornered leaves, unevenly dented about the edges, like unto thoſe of ground Ivie, or the *Cymbalaria*, which leafe is ſomewhat like it, every one upon a ſmall long footeſtalke: at the toppes of the ſtalkes, and ſometimes alſo from the ſides of them, ſtand ſomewhat long blue flowers, like unto the other Bell-flowers, upon long foote ſtalkes.

17. *Rapunculus petræus.* Rocke Rampions.

The roote of this Rampion is long white and of a fingers thickeneſſe, growing ſo faſt into the Rockes that with much labour it can be drawne out whole, being of a ſweetiſh and ſharpe taſte, often taken as a ſallet: it hath divers thicke, and ſomewhat broade leaves, ending in a point, from whence riſe two or three ſlender ſtalkes ſcarſe a foote high, having narrower and longer leaves on them ſet oppoſite, at the toppes whereof ſtand round heads, of many blewiſh flowers ſet together without ſmell, after which follow very ſmall yellowiſh ſeede, as bigge as Poppie ſeede. There is another with thinner leaves and ſmaller flowers.

The Place.

Many of theſe arē ſtrangers to us not growing wilde in our Land that I can heare of, but ſome in *Candy*, others in *Italy*, and ſome in *Germany*, &c. yet ſome of them in divers places of this Land, as the firſt, ſecond, ſeventh, eleventh, and twelfth.

The Time.

They flower all the Sommer long, ſome abiding long, and laſting untill the Autumne cold dewes doē take them away, others ſooner ſpent.

The Names.

Some call theſe *Rapunculi*, and *Rapuntia*, *Geſner*, *Dodonæus* and others call them *Rapa ſylveſtria*, having little likeneſſe at all with *Rapum*, the Turnep, but in the edibleneſſe of the roote, although the name be a diminitive thereof. Others call them *Campanula* of the forme of the flowers, being like little Bells. *Columna* taketh the *Rapunculus minor*, to be *Erinus* of *Nicander* and *Dioſcorides*, and the other *Rapunculi* to be kindes thereof: *Matthiolus* taketh the *Campanula perſici folia*, to be *Phyteuma* of *Dioſcorides*; and *Cæſalpinus* calleth the *Rapunculus ſpicatus ſive Alopecuroides*, *Phyteuma foliis Rapunculi*, chiefely becauſe the heads with ſeede have holes in them, as *Dioſcorides* ſaith the ſeede of his *Phyteuma* hath. The firſt is called *Rapunculus* and *Rapunculus minor* by *Matthiolus*, *Camerarius*, *Dodonæus*, and others; *Tragus* calleth it *Rapunculum vulgare*, and *Lobel Rapuntium parvum ſive Pes locuſtæ Avicennæ*. The ſecond is called *Rapunculum ſylveſtre* by *Tragus*, and by *Dodonæus Rapum ſylveſtre majus*, and *Rapunculum Alopecuron*, by *Lobel Rapuntium majus Alopecuroides comoſo flore*, by *Cluſius Rapunculus Alopecuroides longa ſpica*, by *Thalius Rapunculus ſylveſtris ſpicatus*, and by *Tabermontanus Rapunculus nemoroſus primus*: the third is called by *Cluſius Rapunculus Alopecuroides orbiculari penè ſpica*, by *Columna Rapuntium corniculatum montanum*: the firſt of the fourth kinde *Thalius* calleth *Rapunculus ſylveſtris cæruleus umbellatus minor*, and is the ſecond *Rapunculus umbellatus* in *Camerarius* his figures, at the end of his *hortus medicus*, which *Bauhinus* calleth *Rapunculus umbellatus latifolius*: the ſecond of the fourth kinde, is the firſt *umbellatus* of thoſe three figures of *Camerarius*, and is the *Rapunculus ſylveſtris cæruleus umbellatus major* of *Thalius*, which *Bauhinus* calleth *umbellatus anguſtifolius*; and the third of the ſayd fourth kinde, is the ſeventh *umbellatus* with *Thalius*, and the third of *Camerarius* his figures, which *Columna* calleth *Rapuntium alterum anguſtifolium Alpinum*, and *Bauhinus Rapunculus umbellatus folio gramineo*; the fift is *Petromarula*, *ſeu Lactuca petræa Cretica*, both by *Honorius Bellus*, in his firſt Epiſtle to *Cluſius*, and by *Pona* in his *Mons Baldus*, and by *Ferrantes Imperatus* in his generall Hiſtory, which thereupon *Bauhinus* calleth *Rapunculus Creticus*, *ſeu Pyramidalis altera*: the ſixt is called by *Bauhinus Rapunculus Alpinus ſeu Pyramidalis minor*, and thinketh it to be the *Campanula foliis ſerratis cærulea* of *Beſlerus in horto Eyſtetenſi*. The ſeventh is called by *Thalius Rapunculus Campanulatus Nerij foliis tertius*, and by *Tabermontanus Rapunculus nemoroſus*. The eighth is called by *Columna Rapuntium ſive Erinus magno flore*, and by *Bauhinus Rapunculus nemoroſus magno flore minor*. The ninth and tenth are ſo called by *Bauhinus* as they are in their titles: *Anguillara* taketh the eleventh to be *Cantabrica Plinij*, and *Cæſalpinus Phyteuma unico flore, in ſummis cauliculis*, and is alſo the *Campanula minor rotundifolia* of *Lobel*, or *Alpina rotundioribus imis foliis* of *Cluſius*, which *Bauhinus* would diſtinguiſh, and thereupon hath given as he ſaith, a truer figure of that *Alpina rotundifolia minor*, but aſſuredly they cannot differ, otherwiſe than the place may give it, for that I have ſeene and gathered both theſe ſorts, with the differences ſpecified, in one and the ſame ground almoſt. The twelfth is called by *Tabermontanus Rapunculus ſylveſtris flore ex purpureo candicante*, and by *Gerard Campanula minor, alba & purpurea* for that they grow uſually on the barren dry Heath of *Hampſted*, and other grounds under the buſhes. The thirteenth is called by *Bauhinus Campanula Alpina linifolia cærulea*: the fourteenth by *Tabermontanus Rapunculus nemoroſus tertius*, and by *Bauhinus Rapunculus nemoroſus anguſtifolius parvo flore*, and ſaith it is the ſame with *Gerards Campanula lutea linifolia*. The fifteenth and ſixteenth are ſo named as their titles demonſtrate them by *Bauhinus*, who onely remembreth them: the laſt is remembred by *Alpinus* in *lib. de exoticis*.

The Vertues.

The roo:es of all the ſorts of Rampions, and ſo likewiſe ſome of the Bell-flowers, eſpecially if they have any greater rootes, than the ordinary ſtringie ones, are uſed for ſallets either cold with vinegar oyle and pepper, or boyled and ſtewed with butter or oyle, and ſome blacke or long pepper caſt on them; either way or any way elſe they are familiar to the ſtomacke, ſtirring up the appetite, and by reaſon of their temperate quality, cauſeth a good digeſtion, and engendreth ſtore of milke in nurſes breaſtes; the rootes beaten ſmall, and mixed with ſome meale of *Lupines*, clenſeth the skinne from ſpots, markes, or other diſcolourings. The diſtilled water of the whole plants, rootes and all, performeth the ſame, and maketh the face very ſplendent and cleare.

CHAP.

CHAP. LXXXII.

Digitalis. Foxglove.

ALthough I have ſet forth in my former booke many ſorts of Foxgloves, being all of them prētty ornaments to a Garden that is kept for delight, yet there is one remaining to bee ſpoken of, being commonly knowne to grow wilde in our land, in every countrey almoſt, ſo that it is not thought worthy a place in our Gardens (although in other countries beyond the Seas, where it is not ſo familiar, it is as greatly deſired as any other with us, that is common with them) but I thinke not amiſſe to expreſſe the names of them I have formerly ſet forth, that ſo you may ſee all the ſorts in one place: *Digitalis maxima ferruginea*, Dun coloured Foxgloves, *Digitalis major flore carneo*, Bluſh coloured Foxgloves. *Digitalis media flore luteo rubente*, Orenge tauny Foxgloves. *Digitalis major alba*, The greater white Foxglove. *Digitalis alba altera, ſeu minor*, The leſſer white Foxglove. *Digitalis major lutea flore amplo*, The greater yellow Foxglove, whoſe figure I give you here with the common: and *Digitalis minor lutea, ſive pallida*, The ſmall pale yellow Foxglove.

Digitalis purpurea vulgaris. Common purple Foxglove.

This common Foxglove hath many long and broad leaves lying upon the ground, dented about the edges, a little ſoft or woolly, and of a kind of hoary greene colour, among which riſe up ſundry ſtalkes ſometimes, and but one very often, bearing ſuch leaves thereon, from the bottome to the middle; from whence to the top it is ſtored with large and long hollow reddiſh pulple flowers, a little more long and eminent at the lower edge, with ſome white ſpots within them one above another with ſmall greene leaves at every one, but all of them turning their heads one way, and hanging downewards, having ſome threds alſo in the middle, from whence riſe round heads, pointed ſharpe at the ends, wherin ſmall browne ſeede lyeth; the rootes are many ſmall huskie fibres, and ſome greater ſtrings among them; the flower hath no ſent, but the leaves have a bitter hot taſte.

The Place.

It groweth in dry ſandy grounds for the moſt part, and as well on the higher as lower places under hedge ſides, in every country almoſt of this Land.

The Time.

It flowreth ſeldome before *Iuly*, and the ſeede is ripe in *Auguſt*.

The Names.

It was not knowne unto any of the ancient Greek or Latin writers, for it hath ſcarſe attained a Latin name other then *Digitalis* from the hollow forme of the flowers, which are like finger ſtalles: Some have taken it to bee a kinde of *Verbaſcum*. *Cæſalpinus* calleth it *Virga regia major flore purpureo*, *Aliſma* alſo and *Damaſonium*, and *Fiſtula paſtoris*. *Tragus* calleth it *Campanula ſylveſtris*, *flore purpureo*, and *flore luteo*: *Columna* taketh it to bee the *Ephemerum* of *Dioſcorides*, and *Dalechampius* upon *Pliny* taketh it to bee *Calathiana Viola Plinij*, as I ſayd be-

Digitalis purpurea vulgaris.
Common purple Foxglove.

Digitalis lutea flore amplo.
Foxglove with large yellow flowers.

fore: the *Italians* call it *Aralda* as *Camerarius* saith, the *French* call it *Gent de noſtre Dame*, and *Doigtier*, the *Garmanes* call it *Fingerhuet* and *Fingerkraut*, the *Dutch Vingercruidt*, and we in *Engliſh* Foxgloves.

The Vertues

The *Italians* have an uſuall proverbe with them concerning this herbe, called by them *Aralda* which is *Aralda, tutte piaghe ſalda*: *Aralda* ſalveth all ſores: for they uſe it familiarly to heale any freſh or greene wound or cut, the leaves being but bruiſed and bound too, and ſometimes alſo they uſe the juyce in old ſores to clenſe them, dry up their moyſture, and heale them the more ſpeedily, which it performeth by the bitter quality therein whereby it is found to be heating and drying, and clenſing withall; ſo that whenſoever there is neede of a rarefying, or extenuating of thicke tough flegme and viſcous humours troubling the cheſt or ſtomacke; the decoction or juice hereof made up with ſome Sugar or honey is availeable, as alſo to clenſe and purge the body both upwards and downewards ſometimes, of tough flegme, and clammy humours, and to open the obſtructions of the Liver and Spleene; and yet notwithſtanding that theſe qualities are found to bee in it, there are but few Phyſitions in our times that put it to theſe uſes, but is in a manner wholly neglected: It hath beene found by late experience to be availeable for the Kings Evill, the herbe bruiſed and applyed to the place, or the juice made up into an ointment and uſed thereon: And it hath beene of later experience found alſo to be effectuall againſt the Falling ſickneſſe, that divers have beene cured thereby; for after the taking of the decoction of two handfulls thereof, with foure ounces of *Pollipody*, of the oake bruiſed made in Ale, they that have beene troubled with that diſeaſe 26. yeares, and have fallen once in a weeke or two or three times in a moneth, have not fallen once in 14. or 15. moneths, that is untill the writing hereof, which I thinke may be ſayd to be an abſolute cure, not to be preſumed that after ſo long ſtay it ſhould returne againe.

CHAP. LXXXIII.

Helenium ſive Enula Campana. Elecampane.

ALthough *Dioſcorides*, *Theophraſtus* and *Pliny* that followeth them, did in ancient times account of divers herbes to be called *Helenium*, which were much differing one from another, and which are not ſo well knowne as gueſt at by us in theſe times, what they are, as that *Helenium Ægyptium* of *Dioſcorides* in his Chapter of *Helenium*, and that *Helenium Comogenum*, with whoſe rootes *Coſtus* was wont to be adulterated, as he ſaith in his Chapter of *Coſtus*, if they be not both one; and that *Helenium* of *Theophraſtus* in his ſixt Booke and ſixt Chapter numbred among the ſweete herbes put into Garlands, which may alſo be the ſame with that *Egyptium* of *Dioſcorides*; and although *Bauhinus* in theſe times would referre the *flos Solis*, and the varieties thereof unto it (of ſome whereof I have ſpoken in my former booke) yet I meane not to ſpeake of any of them in this Chapter, but of the moſt ordinary ſort, even the firſt of *Dioſcorides*, which is moſt uſually called *Enula campana*, Elecampane: (and of that which is thought to be *Dioſcorides* his *Heleniũ Ægyptium* in the next:) the deſcription of which you ſhall have in this manner. It ſhooteth forth many large leaves lying neare the ground which are long and broad, ſmall at both ends, ſomewhat ſoft in handling, of a whitiſh greene on the upper ſide, and gray underneath, each ſet upon a ſhort footeſtalke; from among which riſe up divers great and ſtrong hairy ſtalkes, three or foure foote high, with ſome leaves thereon compaſſing them about at the lower ends, and are branched towards the toppes, bearing divers great and large flowers, like unto thoſe of the Corne Marigold, both the border of leaves, and the middle thrumbe being yellow, which turne into downe, with ſome long ſmall browniſh ſeede among it, and is carryed away with the winde: the roote is great and thicke, branched forth divers wayes, blackiſh on the outſide, and white within, of a very bitter taſte, but good ſent, eſpecially when they are dryed, no part elſe of the plant having any ſmell.

Helenium ſive Enula Campana.
Elecampane.

The Place.

It groweth in the moyſt grounds and ſhadowy places oftner then in the dry, and open borders of fields and lanes, and in other waſte places almoſt in every countrey of the Land.

The Time.

It flowreth in the end of *Iune* and *Iuly*, and the ſeede is ripe in *Auguſt*, the rootes are gathered for uſe, as well in the Spring before the leaves come forth, as in Autumne or Winter.

The Names.

It is called in Greeke ἑλένιον, *Helenium* alſo in Latine, and of ſome *Inula*, and *Enula*, and *Enula Campana*: ſome thinke it tooke the name from the teares of *Helen*, from whence it ſprung which is a fable; others that ſhee had

he

her hands full of this herbe, when *Paris* carried her away: others say it was so called, because *Hellen* first found it availeable against the bitings and stingings of venemous beasts; and others thinke that it tooke the name from the Island *Helena*, where the best was found to grow: the *Arabians* call it *Iasin*, and *Rasen*, the *Italians L'ella*, and *Enola* and *Enoa*, the *Spaniards Raiz de alla*, the *French Aunee* and *herbe Alaine*, the *Germans Alant*, and *Alantwurtz*, the *Dutch Alantwurtel*, and *Galantwurtel*, and we in *English* Elecampane generally, yet in some countries of this kingdome Scabwort and Horseheale *Anguilara* and *Cordus* tooke it to be *Panax Chironium Theophraste*.

The Vertues.

The fresh rootes of Elecampane preserved with Sugar, or made into a syrupe or conserve, are very effectuall to warme a cold & windy stomack, and the pricking and stitches therein, or in the sides caused by the Spleene, and to helpe the cough, shortnesse of breath, and wheesing in the Lungs: the dryed rootes made into powder mixed with Sugar, and taken, serve to the same purposes, and is also profitable for those that have their urine or their menstrues stopped, those that are troubled with the mother, or are pained with the stone in their reines, kidneys or bladder: it resisteth poyson, and stayeth the spreading of the venome of Serpents, &c. as also of putrid and pestilentiall Fevers, and the Plague it selfe; for which purpose it is put into Treakles, and other medecines for that disease. *Iulia Augusta* as *Pliny* writeth in his 19. Booke and 5. Chap. let no day passe without eating some of the rootes of *Enula* condited, which it may be shee did to helpe digestion, to expell melancholy and sorrow, and to cause mirth, and to move the belly downewards, for all which they are also effectuall: the rootes and herbe beaten and put into new Ale or beare instead of wine, as they use in *Germany*, *Italy* and other places, and daily drunke of them that have weake and dim sights, cleareth, strengthneth and quickneth the sight of the eyes wonderfully, the decoction of the rootes in wine, or the juice taken therein, killeth and driveth forth all manner of wormes in the belly, stomacke, or mawe, and gargled in the mouth, or the roote chewed fasteneth loose teeth, and helpeth to keepe them from putrefaction: the same also drunke is good for those that spit blood, helpeth to remoove Crampes or Convulsions, and the paines of the Goute, and the huckle bone, or hip-goute called the Sciatica, the looseneesse and paines in the joynts, or those members that are out of joynt, by cold or moisture happening to them, applyed outwardly as well as inwardly, and is good also for those that are burstен or have any inward bruise: the rootes boyled well in vinegar, beaten afterwards, and made into an oyntment, with Hogs Suet or oyle of trotters, & a little salt and vinegar in powder added thereto, is an excellent remedy for any scabs or itch, in young or old; the places also bathed or washed with the decoction doth the same; the same also helpeth all sorts of old putrid, or filthy sores or Cankers whersoever. In the rootes of this herbe lyeth the chiefe effect for all the remedies aforesayd, yet the leaves are sometimes also used to good purpose: And the distilled water of them, and the rootes together is used also in the like manner, and besides is very profitable to cleanse the skinne of the face or other parts from any morphew, spots, or blemishes therein, and causeth it to be cleare.

CHAP. LXXXIIII.

Helenium alterum Dioscoridis, sive Helianthemum. Dwarfe Cistus or small Sunflower.

ACcording as many good Authors doe, I account this herbe for the second *Helenium* of *Dioscorides*, although it hath received other names by divers writers, and therefore joyne it next thereunto, and because it much resembleth some other sorts of Cistus, I thinke it fit to entreate of them in the succeeding Chapters, and not mingle them together, for of these kinds there are many sorts, some whereof I have set forth in my former booke, which are the *Camæcistus Frisicus*, the Dwarfe Holly Rose of *Freezeland*, and *Cistus ananus*, the Holy Rose of a yeare, which I shall not neede to describe againe in this place, but referre you thither where you shall finde them, yet I will here give you their figures.

1. *Helianthemum vulgare, sive Chamæcistus flore luteo & Flos solis quorundam.*
The ordinary yellow Dwarfe Cistus or small Sunflower.

This low or Dwarfe Cistus sendeth forth from a hard wooddy browniſh root, growing in time to be somewhat great, but not very long, and divided into small branches at the lower end, sundry small and weake, yet hard and almost wooddy branches, lying for the most part round about the head of the roote, upon the ground, whereon are set by couples many small and somewhat long leaves, a little soft or hairy, with other small leaves also growing betweene them: at the toppes whereof stand three or foure small pale yellow and sometimes gold yellow flowers, consisting of five round pointed leaves a peece, with some yellow threds in the middle, of a pretty sent in some places, but lesse or none in others; after which follow small round heads, containing therein small yellow seede: this dyeth not but abideth many yeares, increasing in branches, which yeeld a viscous or muciliginous juice, like unto Comfrey, and is of an austere and astringent taste.

2. *Helianthemum flore albo.* White Dwarfe Cistus or small Sunflower.

This Cistus differeth little from the former, but that it riseth somewhat higher, the leaves being a little whiter and longer, and not set so thicke together: the flower also is somewhat longer and white, in some places being a little sweete, and in others little or nothing at all, but an astringent taste like the other.

3. *Helianthemum Sabaudicum.* The Savoy small Sunflower or Dwarfe Cistus.

This is likewise one of the same kind, differing very little from them, having flexible but tough reddish branches, standing somewhat more upright, and divided into other lesser, with foure small narrow leaves usually set at a joynt contrary to all the rest, yet the flowers are like the others, being in some yellow, in others white; the seede and roote are not unlike.

4. *Helianthemum angustifolium.* Narrow leafed small Sunflower or Dwarfe Cistus.

This small low or Dwarfe Cistus is likewise a small plant, having most of the branches lying on the ground, with leaves set thereon but in a different manner from all the rest, that is confusedly, for they are very many, small and narrow, and in a manner hoary or white; at the tops of the stalkes rise up small whitish or pale yellow flowers, like in forme unto the other, with small threds in the middle: the heads that follow are small and three square, like unto those of Line or Flax, with reddish seede in them; the roote is wooddy and fibrous.

5. *Chama-*

1. *Helianthemum vulgare.*
The ordinary dwarfe Ciſtus or ſmall Sunflower.

3. *Helianthemum Sabaudicum.*
The *Savoy* Dwarfe Ciſtus.

5. *Chamæciſtus latifolius.* Broad leafed ſmall Sunflower or Dwarfe Ciſtus.

The ſmall branches of this low or Dwarfe Ciſtus doe lye on the ground, but the leaves are ſomewhat broader then in any of the former, neareſt in forme unto ſmall Mirtle leaves, and pointed at the ends: above the leaves on a ſmall ſtalke ſtand foure or five ſmall yellow flowers like the reſt; the heads for ſeede are three ſquare, and the ſeede within them ſomewhat rough and reddiſh; the roote is like the reſt abiding long.

6. *Chamæciſtus hirſutus.* Dwarfe Ciſtus with rough leaves.

The ſtalkes of this low Ciſtus grow more upright then the former, more blacke alſo and more woddy, about halfe a foote in length, having ſo many ſmall, rough and hairy darke greene leaves ſet thereon, ſomewhat like the laſt, and ſo thicke that they ſeeme to have foure at a joynt: at the toppes of the ſtalkes and branches for they are divided into ſmaller ones, ſtand uſually but one ſomewhat large flower, and ſometimes two, conſiſting but of one leafe, yet cut in ſo deepe that it ſeemeth to be five round pointed leaves, of a pale purple or light bluſh colour, with a long purpliſh ſtile, or pointell in the middle, compaſſed about with ten ſmall chives, tipt with blackiſh chives, after which come five ſquare round heads, conteining ſmall yellow ſeede: the root is wooddy and ſpreading.

7. *Chamæciſtus Ericæ foliis.* Heath leafed Dwarfe Ciſtus.

This Dwarfe Ciſtus is likewiſe a ſmall plant, having moſt of the branches lying on the ground, and ſome bearing themſelves upright, which are of two ſorts, the one with very ſhort leaves, which is the lower, and in the other which riſeth higher much longer, ſet both ſo ſmall that they are moſt like unto the leaves of Heath, or Tamariske, with ſmall

Chamæciſtus Friſicus. The Dwarfe Ciſtus of *Freezeland.*

yellow

yellow flowers at the toppes of them, like unto the former, after which come ſmall heads that ſwell out in the middle are ſtraked and yellowiſh, & containe within them ſmall round ſeede like Millet, but greater: the roote is ſomewhat long, hard and wooddy, blackiſh on the outſide with divers long fibres thereat.

8. *Chamæciſtus Serpilli folio flore luteo.* Yellow Dwarfe Ciſtus with wilde Time leaves.

This Dwarfe Ciſtus creepeth upon the ground, like unto wild Time, with ſuch like ſmall leaves ſet upon the reddiſh branches very thicke, or as it were in a double row, of a darke greene colour, and a little hairy withall, but a little longer and whiter next unto the flowers, which ſtand three or foure together, every one on a pretty long hairy footeſtalke; conſiſting of five ſmall yellow leaves like unto the other and ſomewhat ſweete: the roote is very fibrous or much ſpread under ground.

9. *Chamæciſtus Serpilli folio flore carneo.* The great Dwarfe Ciſtus with wilde Time leaves.

This other wilde Time leafed Ciſtus hath creeeping blackiſh branches, farther extended upon the ground then the other being about a foote in length, and taking roote as they creepe, having ſuch like but ſmall leaves ſet thereon by couples, of a ſad greene colour on the upper ſide, and grayiſh underneath: at the ends of the branches ſtand three or foure flowers together, made of five leaves a peece, of a kind of bluſh colour: the heads that beare the ſeede are five ſquare, and open themſelves at the toppes ſhewing very ſmall ſeede; the roote is ſmall and wooddy: all theſe ſorts of Dwarfe Ciſtus or Sunflowers are durable, not periſhing in the Winter.

The Place.

The firſt and ſecond grow in divers places of this land, but eſpecially in *Kent*, in every tract thereof throughout, which in ſome places is greater then in others, yet that with the white flower is more rare to finde then the others: the third according to the title in *Savoy*: the fourth *Cluſius* ſaith he found on the hills about the Bathes of *Baden*: the fift he likewiſe ſaith groweth plentifully on the Alpes of *Auſtria* and *Hungary*: the ſixt alſo upon the ſnowy hills of the Alpes: the ſeaventh on the open ſunny ſandy hills in divers places of *France*, *Spaine*, and *Italy*: the eighth *Cluſius* ſaith hee never found but upon the higheſt Alpes of *Auſtria* and *Stiria*; and as ſome thinke is that ſort is moſt uſuall with us here in *England*: the laſt alſo on the ſnowy hills of the Alpes.

The Time.

All theſe ſorts of Dwarfe Ciſtus doe flower in the Summer, ſome earlier and later then other by a moneth, yet moſt of them are ſo ſoone fading, that their flowers endure but a day or two, and perfect their ſeede ſoone after.

The Names.

I am verily perſwaded that *Dioſcorides* hath made mention of this herbe in two ſundry places of his worke, the one in the Chapter of *Helenium* which he ſaith *Crateuas* called Ἑλένιον Αἰγύπτιον *Helenium Ægyptium*, and grew like *Serpyllum*, unto which *Pliny* alſo in his 29. Booke and 10. Chap. conſenteth, ſaying *Helenium* is ſayd to grow of *Hellens* teares, and the beſt to grow in the Iſland *Helena*: it is a ſmall ſhrubbe lying on the ground, with leaves like unto *Serpyllum* or mother of Time, and in the 22. Chap. of the ſame Booke hee remembreth it againe and giveth the vertues thereof, which are differing from the other *Helenium* or Elecampane; for he there ſaith, that the juice thereof is ſweete, and being drunke in wine is a furtherer of mirth, and may be held to be the *Nepenthe*, whereof *Homer* ſpeaketh, that putteth away all ſorrowes: but ſome thinke that this differeth from the *Helenium* of *Theophraſtus*, becauſe he numbreth it ſtill among ſweete herbes that were uſed in Garlands, as *Serpyllum*, *Siſymbrium*, and *Abrotanum*, and therefore judge it to be *Marum*, or herbe Maſticke: the other place in *Dioſcorides* is in his Chapter of *Panax*, and called Πανακες χειρωνιον *Panax*, and *Panaces Chironium*, which hee there ſaith hath leaves like unto *Amaracus* or Marjerome and yellow flowers, and a ſmall roote; all know the leaves of Marjerome doe not much differ from *Serpyllum* in the forme, but in the largeneſſe and hoary whiteneſſe: and therefore divers Authors doe call it diverſly; ſome, as *Lugdunenſis* calleth it *Helenium minus Dioſcorides*, and others *Helenium alterum, ſive Ægyptium*, and ſome *Panax*, and *Panaces Chironium* as *Matthiolus* and others that follow him, or *Chironia* as *Cæſalpinus*: ſome alſo take it to be *Helianthe* of *Pliny*, which *Cordus* calleth *Heleanthemum*, or *flos Solis*, and ſo doe *Lobel*, *Thalius*, *Tabermontanus* and divers others: *Geſner in hortis Germaniæ* calleth it *Gratia Dei*, or *Hyſſopoides*, for the likeneſſe of the leaves, which deceived both him and *Tragus*, who called it *Hyſſopus campeſtris*, and *Lonicerus* who called it *Hyſſopus montana, ſive ſylveſtris*, who all follow the common appellations of their countries. *Cordus* ſaith it was called by divers in his time, *Conſolida aurea* & ſo ſaith *Cluſius* alſo, yet he would nather referre all theſe ſorts to the family of the female Ciſtus, and make them of his third order of Ciſtus, calling them *Chamæciſtus*, becauſe they are like unto them, both in face and propertie. *Lobel* in his *Adverſaria* would rather referre it to the *Centaurium luteum*, whereunto as he ſaith it is both in face and vertue not unlike: the firſt which is as uſuall with us as in *Germany* is called of the *Germans Heyden Yſſop*, that is, Heathen Hyſſope we may call it in *Engliſh*, and ſo the reſt, eyther ſmall Sunflower or Dwarfe Ciſtus: the third is remembred by *Tabermontanus* under the ſame title, it is expreſſed here: the fourth is the ſixt *Chamæciſtus* of *Cluſius*: the fift is his third *Chamæciſtus* in his Hiſtory of Plants, but are the firſt and ſecond in his *Pannonicke* obſervations, and there called *Anguſtifolius* and *Latifolius*, as *Bauhinus* doth alſo: the ſixt is *Cluſius* his eighth *Chamæciſtus*, and called by *Tabermontanus Ciſtus humilis Auſtriaca*, by *Bauhinus Chamæciſtus hirſuta*: the ſeventh is called by *Lugdunenſis Erica Chryſanthemos*, and by *Bauhinus Chamæciſtus Ericæfolio luteus*, who judgeth it to bee the *Cori ſimilimus frutex in maritimis* of *Cæſalpinus*, and the *Coris Dioſcoridis* of *Guilandinus*: the eighth is the ſecond *Chamæciſtus* of *Cluſius*, which *Tabermontanus* calleth *Ciſtus humilis Serpillifolia*, and I thinke may bee the *Helianthes ſpecies rara*, in the *Adverſaria* of *Pena* and *Lobel*, which *Lobel* afterwards in his *Icones* calleth *Ciſtus majoranæ foliis*; and *Bauhinus* maketh to be a *Ciſtus fœmina*, numbring it among them: the laſt *Cluſius* in his *Pannonicke* obſervations, was not well reſolved by what name to call it, as partaking both with *Cneorum Matthioli*, & *Chamæciſtus*, and therefore left it there as an *Anonima*, without name, but conſidering afterwards better upon it, he ſetteth it forth in his hiſtory of Plants for his ſeventh *Chamæciſtus*. *Bauhinus* calleth it *Chamæciſtus Serpylli folia floribus carneis*, and taketh it to be the *Roſa Alpina altera foliis minimis* of *Geſner in hort.* and the *Alpina altera* of *Lobel*.

The Vertues.

All theſe ſorts are drying and binding or aſtringent, with ſome bitterneſſe joyned thereto, eſpecially in ſome more then in others, and not without ſome ſmall ſent alſo: the decoction of this herbe and roote, is ſingular good for

for them that ſpit blood, and to ſtay all bleedings, eyther inward or outward, as alſo all fluxes or laskes, and the aboundance of womens courſes: the ſame alſo is very effectuall to waſh ſore mouthes, and the Vlcers that happen in the privy parts of man or woman: it is no leſſe profitable in other Vlcers of the body or legges, which are long kept from healing, by a deſluxion of moiſt and ſharpe humours falling upon them, which it conſumeth and dryeth up, thereby cauſing the ſores to heale the more ſpeedily: it likewiſe ſodereth and cloſeth up the lippes of greene wounds, for it is very powerfull in conſolidating, binding, and ſtrengthning any part, and is as effectuall as any Comfrey for burſtings, the ſtrengthning of weake joynts, or any other binding propertie, whereunto any Comfrey may be applied: being bruiſed and applyed to the biting or ſting of any venemous creature, it ſtayeth the venome from further ſpreading, and healeth the party quickly; eſpecially if they take alſo of the juice, or the decoction thereof in wine: the diſtilled water of the herbe is held to beautifie the skinne of the face, or any other part of the body.

Chap. LXXXV.

Ciſtus mas. The male Holly, or Sage Roſe.

Becauſe I entreated in the laſt Chapter of the ſmall or Dwarfe Ciſtus, which upon good ground as I take it I referred to the *Helenium alterum* of *Dioſcorides*; I thinke it not amiſſe here to proſecute the other kinds of Ciſtus, whereof there are two principall, one that beareth the ſweete Gum *Ladanum*, and another that doth not, according as ſome doe diſtinguiſh them; or as others doe into male & female; yet ſome make three kinds, and the Ciſtus *Ledon* to be the third, but it may bee comprehended under the female kind, in that it beareth white flowers as the female doth, the male alwayes bearing red flowers: but becauſe there is ſo much varietie in every of them, I will diſtribute them into their ſeverall Chapters, not intending to ſpeake of thoſe here, I have ſpoke of in my former booke, which is one of eyther of the two firſt ſorts, and two or three of the laſt, yet if I give you their figures, it ſhall be to ſhew you their differences.

1. *Ciſtus mas anguſtifolius.* Narrow leafed male Ciſtus.

This ſmall Ciſtus groweth like a ſmall ſhrubbe or buſh, with divers wooddy branches thereon, ſet with leaves on each ſide two together, which are longer and narrower, ſofter alſo, and not altogether ſo hoary or woolly as that ſort which I have already ſet forth, elſe not differing from it, for the flowers are like unto thoſe of the wild Eglantine or Brier Roſe, of a fine delayed reddiſh colour, like unto the other, as the heads and ſeede are alſo; this roote is wooddy and groweth not deepe: this is ſomewhat more tender to keepe, and will leſſe abide the injuries of our Winter froſts then the former.

2. *Ciſtus mas folio ſubrotunda.* Round leafed Male Ciſtus.

This other Ciſtus is ſomewhat more woolly then the former, and his leaves are larger, rounder, and more rough

Ciſtus mas vulgaris
The more ordinary male Ciſtus.

1. *Ciſtus mas anguſtifolius.*
Narrow leafed male Ciſtus.

then

then it: the flowers alſo are ſomewhat larger and of a deeper colour, and the heads of ſeede bigger, hard and hairy as the other, with reddiſh ſeede in them, and herein conſiſteth the chiefeſt differences from them.

3. *Ciſtus mas folio breviore.* Small leafed male Ciſtus.

This ſmall Ciſtus for ſo I may call it, as well in reſpect of the growth being lower, and the branches ſlenderer, then in any of the other as in that the leaves hereof are ſmaller and ſhorter then in the firſt here ſet forth, and are alſo greener, and rougher and more clammy and ſweeter alſo then any male Ciſtus: the flowers are of a paler colour like in forme unto the other, but ſomewhat larger and ſweet, which is not found in any other of this ſort, and abide longer in their huskes before they fall; in other things it differeth not.

4. *Ciſtus mas humilis.* The low male Ciſtus.

This Ciſtus groweth lower, bending downe his many branches from the roote almoſt to the ground, not much above halfe a yard long, the leaves that are not ſet by couples, as in the other ſorts of Ciſtus are ſmall and crumpled, unevenly waved as it were on the edges white and hoary: the flowers that ſtand at the end of the branches are many ſet together of an equall height, in forme of an umbell, or tuft, or noſegay, but ſmaller, yet of a brighter reddiſh purple, then are in the ſecond ſort here ſet forth: the heads which containe blackiſh ſeede, are ſmaller then in the other, and are almoſt hidde in the ſmall huskes that hold them.

The Place.

All theſe ſorts grow in *Spaine* and *Portugall*, and ſome of them in *France* and *Italy*.

The Time.

They all doe flower in *May* in their naturall places, but about Midſomer with us, and ſometimes earlier.

The Names.

It is called in Greeke χίστος and χίσθος, *Ciſtus* and *Ciſthus* which the Latines alſo doe hold, not having any other name whereby to expreſſe it: ſome alſo call it χίσσαρον and χίσσαρον, *Citharon* and *Ciſſaranos* peradventure derived from χίσσος *Ciſſus Hedera*, which cauſeth *Pliny* his errour; for in writing of *Hedera* in his 16. Booke and 34. Chap. hee ſaith it is of two ſorts, male and female, &c. which in his 24. Booke and 10. Chap. hee ſaith the Ciſtus hath: but it may bee *Pliny* was herein deceived by a falſe copy of *Theophraſtus*, which hee followed which had χίσσος inſtead of χίσθος for *Gaza* in tranſlating of *Theophraſtus*, doth fall into the ſame errour with *Pliny*, making *Hedera* to bee male and female, with flowers like Roſes but aſſuredly unleſſe the copies were falſely written, which bred that errour, we cannot judge that *Theophraſtus*, who had written ſo exactly in another place of the ſeverall ſorts of Ivie, ſhould be ſo much forgotten in this, to ſay Ivie hath flowers like Roſes, &c. Some call it *Roſa Sylvatica*: the *Arabians* call it *Ramich Altheis*, or *Ibaio althis*: the *Italians Ciſto maſchio*: the *Spaniards Corynacos* and *Eſtopa*: the *Portugalls Roſella*: the *French* and *Dutch Ciſte*, and we in *Engliſh* male Ciſtus likewiſe or the Sage Roſe, becauſe the leaves of the one ſort are rugged and hoary like Sage leaves, and the flowers like ſingle Roſes, but why *Gerard* ſhould call it the Holly Roſe I ſee no reaſon, having no reſemblance unto Holly, but becauſe that name hath beene long impoſed upon it, I will let it ſo paſſe. All theſe ſorts of Male Ciſtus, with the other ſet forth in my other booke, are remembred by *Cluſius* in his Hiſtory of Plants, and neede not further amplification.

Ciſtus mas breviore folio.
Small leaſed male Ciſtus.

The Vertues.

The Male Ciſtus is drying and aſtringent, and not without ſome little heate, yet ſome thinke it to bee cold, and is very profitable to ſtay bleedings at the mouth or noſe, vomitings, and weakeneſſe of the ſtomacke, and fluxes of blood or humours in man or woman, as the Laske, the Blooddy flix, and all other extraordinary ſcowrings or looſeneſſe of the belly, and womens inordinate courſes: the flowers ſaith *Dioſcorides* and *Galen* are the moſt effectuall for thoſe purpoſes, to be drunke in red wine, yet the leaves and young ſhoots or buddes may bee uſed with good ſucceſſe: and theſe applyed in a ſerote to any ſcalding or burning of fire or water doth heale them quickly: they alſo bruiſed and layd to any greene wound, cloſeth the lippes thereof and reſtraineth the bleeding: the leaves alſo, and the young ſhootes boyled in wine, and filthy or old Vlcers waſhed with the decoction thereof, yea although they be cankrous, eating or ſpreading Vlcers, will wonderfully and quickly ſtay the freting moyſt humors, and dry and heale them: the diſtilled water of the leaves and flowers is of the like efficacie, and in all things where there needeth drying, binding and ſtrengthning, this is to very good purpoſe applied.

CHAP. LXXXVI.

Ciſtus fœmina. The female Ciſtus.

THe female Ciſtus as I ſayd before is diſtinguiſhed from the male, in that it beareth not red flowers like it, but white or yellow, whereof there are many ſorts as the ſucceeding deſcriptions doe declare not intending to ſet downe in this place that ſort that is expreſſed in my former booke, and is the firſt of *Cluſius* in his Hiſtory of Plants, although I ſhew you the figure thereof.

1. *Ciſtus fœmina folio Halimi major.* The greater Sea Purſlane leafed Ciſtus.

This kinde of Ciſtus groweth up with ſlender hoary brittle branches, two or three foote high uſually at the moſt, plentifully ſtored with thicke hoary leaves, very like unto Sea Purſlane; ſomewhat round pointed, two alwayes ſet at a joynt, one oppoſite to another as is uſuall in moſt of the ſorts of Ciſtus; the tops of the branches are furniſhed with many yellowiſh flowers leſſer then thoſe of the firſt female Ciſtus, with ſome yellow threds in the middle of them, after which come ſomewhat long and three ſquare heads conteining within them ſmall browniſh ſeede.

2. *Ciſtus fœmina folio Halimi minor.* The leſſer Sea Purſlane leafed female Ciſtus.

This other Ciſtus riſeth up more high and upright then the former, but no leſſe hoary, and ſet with ſomewhat narrower and longer leaves then the former, and more pointed at the ends, the middle ribbe at the backe of the hoary leaves, being greater then in the other, yet both of an auſtere, ſharpe, and binding taſte, the flowers have not beene obſerved by *Cluſius* who firſt ſet it forth, and from whom all others have expreſſed it.

3. *Ciſtus fœmina folio Sampſuchi.* Marjerome leafed Ciſtus.

The ſlender weake branched ſtalkes of this Ciſtus are thicke ſet with many ſmall hoary leaves, very like unto Marjerome, but ſomewhat leſſer, and with a thicker ribbe on the backe of every leafe, two together as is uſuall in the reſt: the flowers are ſmall and white, compoſed of five round pointed leaves, with a darke purpliſh ſpot at the bottome of every leafe, with divers yellow threds in the middle; the ſeede hereof is grayiſh, that followeth in ſmall three ſquare heads.

4. *Ciſtus fœmina Lavendula folio.* Lavender leafed Ciſtus.

The chiefeſt difference in this Ciſtus from the laſt is in the leaves, being ſmall and long like unto Lavender, yea ſo like that as *Cluſius* ſaith, he verily thought them plants to be Lavender that he firſt ſaw, and ſo neglected them untill ſeeing the flowers upon them which were wholly white, without any ſpot in them, he plainely then ſaw that it was a kind of Ciſtus.

5. *Ciſtus fœmina folio Thymi.* Time leafed Ciſtus.

The ſtalkes of this Ciſtus are browniſh and wooddy, riſing a foote high for the moſt part without any leaves

Ciſtus fœmina vulgaris.
The ordinary female Ciſtus.

1. *Ciſtus fœmina Halimi folio major.*
The geater Sea Purſlane leafed female Ciſtus.

upon

2. *Ciſtus Halimi folio minor.*
The leſſer Sea Purſlane leafed female Ciſtus.

Ciſtus annuus flore guttato.
Spotted annuall Ciſtus.

6. *Ciſto ſimilis frutex exoticus.*
The Ciſtus like ſtrange ſhrubbe.

7. *Ciſtus annuus folio Salicis.*
Willow leafed annuall Ciſtus.

upon them but toward the toppes: there ſtand many ſmall greene leaves at a joynt, very like unto thoſe of Time; the flowers are ſmaller then in the other, and wholly white like unto the reſt.

6. Ciſto ſimilis frutex exoticus. The Ciſtus like ſtrange ſhrubbe.

I muſt needes joyne this ſhrubbe unto the reſt, ſeeing *Lobel* who firſt ſet it out did ſo account it, and all others that have mentioned it ſince him doe referre it thereto, although it have ſmall likeneſſe but in the leaves unto any of them (for as I have ſayd before, and the rule is moſt certaine, the flowers and ſeede of any plant doe beſt demonſtrate under what *genus* any *ſpecies* is to be referred, which in this is farthеſt remote, having round woolly heads) and I thinke none of us ever ſaw the plant, but as *Lobel* ſaith it hath wooddy branches like unto a Ciſtus, with rugged long leaves thereon, like unto thoſe of Sage or Mints, and round woolly heads at the toppes like unto Plane tree heads.

7. Ciſtus annuus folio ſalicis. Willow leafed annuall Ciſtus.

The Willow leafed Ciſtus of a yeare (for I have given another of this ſort in my former booke whoſe figure I here give you) hath divers ſmall hairy leaves lying upon the ground, ſomewhat like in forme to Ollive or Willow leaves, but much ſmaller, among which riſe up hairy ſtalkes about a foote and a halfe high, ſet with two leaves at a joynt, much ſmaller then thoſe below, at the toppes whereof grow many ſmall pale yellow flowers, and ſometime more white one above another without any ſpots on the leaves, as in that other is ſet forth already, which do ſcarſe abide a day but ſuddenly fall, the ſeede veſſells that are skinny and three ſquare, containing ſmall ſeede appeare quickly after.

8. *Ciſtus annuus folio Ledi.* Ledum leafed annuall Ciſtus.

This other Ciſtus riſeth higher with greater ſtemmes but not leſſe hairy then the other, having two or three leaves ſet at the ſeverall joynts, longer and narrower then the laſt, and ſmaller pointed, ſomewhat rough, and of a deeper greene colour: the flowers fade as quickly, and grow ſingly towards the toppes, with the leaves as large as the laſt, and of a faire pale yellow colour: with heads and ſeede ſucceeding in the like manner and yearely periſhing alſo, yet it hath ſometimes abidden a Winter in my Garden when it hath not flowred with me in the Summer before.

The Place.

Some of theſe grow in *Spaine*, and ſome upon the cold Alpes and Mountaines in *Germany*.

The Time.

They flower ſome in *Aprill* and *May*, or ſooner in their naturall places, but not untill *Iune* with us, or in *Iuly*.

The Names.

Their names are ſufficiently expreſſed in their titles, as they are uſed to be called of thoſe that have written of them; onely I would give you to know thus much, that the *Spaniards* as *Cluſius* and *Lugdunenſis* from *Mieonus* doe ſay, doe call the annuall Ciſtus, as well that which hath ſpots, as that which hath none on the flowers, by the name of *Turmera*, from *Turmas* which ſignifieth *Tubera*, thoſe *Spaniſh* or outlandiſh puffes that are edible or fit to be eaten; becauſe where that ſhrub groweth they uſually finde thoſe puffes doe breede, and therefore *Lugdunenſis* calleth it *Tuberaria*, and both *Cluſius* and he doe thinke it may be the *Hydnophyllon* of *Pamphylus* in *Athenæus*, becauſe it ſhewed where thoſe puffes doe grow.

The Vertues.

The female Ciſtus are no leſſe drying and aſtringent then the male, and are uſed with as good ſucceſſe, for all the purpoſes before recited, whereunto the male kinds are applied, and therefore it ſhall not neede to repeate the ſame things againe.

CHAP. LXXXVII.

Ciſtus Ledon. The ſweete Gum Ciſtus.

THere are more varieties of this ſweete or Gum Ciſtus then of both the other ſorts before, chiefly differing in growth & leaves, yet all of them ſmelling ſomewhat ſweet of that viſcous or clammy dewines that is upon them. Vnto them alſo are to be referred ſome other plants for the likeneſſe and neareneſſe, ſome whereof I have expreſſed in my former booke, and therefore neede not here againe deſcribe them.

1. *Ciſtus Ledon latifolium.* Broad leafed ſweete Ciſtus.

The broad leafed ſweete Ciſtus riſeth up with divers wooddy branches five or ſix foote high, ſpreading many other ſmaller branches, whereon are ſet two leaves at a joynt one againſt another, ſomewhat broader then that in

in my former booke, comming neare to the forme of Bay leaves, of a darke ſhining greene colour on the upper ſide, and grayiſh underneath, which are clammy in feeling as the young ſhoots and ſtalkes are alſo, and of a ſtrong ſweet ſent to be felt a great way off, eſpecially in the hot Summer time, & in the naturall places, much more then in theſe conutries: at the toppes of every branch come forth ſingle white flowers, made of five broad round pointed leaves, ſometimes without any ſpots in them, as is alſo to bee ſeene in that other with narrow leaves formerly deſcribed, and ſometimes having a darke purple ſpot at the bottome of every leafe pointed upwards, which in ſome are greater in others leſſer, with divers yellow threds in the middle: after the flowers are paſt there come in their places ſomewhat round great hard heads, conteining within them ſmall browniſh ſeede; the root is wooddy, and ſpreadeth many branches but not very deep. *Lobel* maketh mention of a ſort hereof which hee calleth *Latifolium* or *Myrtifolium*, which hath ſundry leaves comming forth together in other things little differing from the former. *Myrtifolium ſeu Latifolium Lobelij.*

2. *Ciſtus Ledon Populnea fronde major.* The greater ſweete Ciſtus with Poplar like leaves.

This greater ſweete Ciſtus riſeth not ſo high as the former, but about three foote, the brittle branches have leaves ſet on them, in the ſame manner that they are in the former, that is two at a joynt one againſt another, but are larger then in any ſort of Ciſtus, being like unto the leaves of Ivie, or the blacke Poplar tree, broadeſt at the ſtalke, and pointed long at the end, greene on the upper ſide and grayiſh underneath, ſomewhat thicke and rough in handling, not having whiſe they are young any clammineſſe or ſweereneſſe on them at all, but onely when they are growne old: the flowers are wholly white, and ſmaller then in eyther of the former, yeelding five ſquare pointed heads, with ſmall blackiſh ſeede in them.

3. *Ciſtus Ledon Populnea fronde minor.* The ſmaller ſweet Ciſtus with Poplar leaves.

This other Ciſtus is in all things like the laſt, but that it groweth much lower, and the leaves although of the ſame forme, yet much ſmaller.

4. *Ciſtus Ladanifera Cypria.* The ſweete Gum bearing Ciſtus of *Cyprus*.

This Candy kinde of ſweete Gum Ciſtus groweth with his blackiſh ſpreading branches not much above two foote high, whoſe blackiſh greene leaves are not ſo large as the firſt here ſet forth, nor ſo narrow as that kind which is expreſſed in my former booke but betweene them both, plentifully ſtored (no doubt) in the naturall countrey with that ſweete clammy dew or gum that is in the others of this kind, although nothing ſo much in theſe colder Tranſalpine countries: the flowers are white like unto the ſecond ſort here expreſſed, and ſo are both heads and ſeede.

5. *Ciſtus Ledon hirſutum ſive quartum Cluſii.* The ſweete Gum Ciſtus with hairy leaves.

The leaves of this Ciſtus are ſofter then in others, and ſomewhat hairy, being long and narrow, but round pointed, ſet on the ſlender weake branches that are ſcarſe two foote high, but as full of that clammy gummineſſe, as in any other, as well when they are young as old: the flowers are ſmall and white like unto thoſe of the female Ciſtus: the ſeede that followeth them in great skinny heads is black but larger then in any of the reſt.

Ciſtus Ledon anguſtifolium.
Narrow leafed Gum Ciſtus.

Ciſtus Ledon Myrtifolium Lobelij.
Lobel his broad leafed ſweete Gum Ciſtus.

2. *Ciſtus Ledon Populnea fronde major.*
The greater ſweete Ciſtus with Poplar like leaves.

3. *Cuſtus Ledon Populnea fronde minor.*
The ſmaller ſweete Ciſtus with Poplar leaves.

5. *Ciſtus Ledum hirſutum ſive quartum Cluſii.*
The ſweete Gum Ciſtus with hoary leaves.

6. *Ciſtus Ledon Oleæ foliis.* The ſweete Ciſtus with Olive like leaves.

This Ciſtus hath ſtronger wooddy blackiſh branches then the reſt, whoſe flat and clammy leaves are long and narrower then thoſe of the Olive tree; the flowers hereof are white, but the ſmalleſt of any of this kind, the ſeede is ſmall and browne.

7. *Ciſtus Ledon anguſtis foliis.* Narrow leafed ſweete Ciſtus.

This ſweete Ciſtus is very like the firſt, but that the leaves arē narrower then they and the white flowers larger; the branches and leaves have ſuch ſweete Gum on them, as is on the others of this kinde.

8. *Ciſtus Ledon ſeptimum Cluſii, ſive Roſmarinis hiſpidis foliis.*
Sweete Ciſtus with hoary rough leaves.

The many branches of this ſweete Ciſtus are of an aſh colour, plentifully ſtored with long and narrow leaves like Roſemary, all hoary, and rough withall, yet clammy with that ſweet Gum upon them as is in the former: the flowers are many ſmall and white like the reſt.

9. *Ciſtus Ledon octavum, ſive Roſmarinis foliis ſubtus incanis.*
Hoary Roſemary leafed ſweete Ciſtus.

The branches of this Ciſtus are not much greater but more ſpread abroad then the laſt: the leaves are thinner but long and narrow, greene above and whitiſh underneath, like as the ordinary Roſemary hath, as clammy with that ſweete Gum as others; the flowers are many, ſmall and yellow that ſtand all along on the ſtalkes, and the toppes of the branches: the ſeed is of a blackiſh gray colour.

10. *Ciſtus Ledon Roſmarinis foliis ſubtus non incanis.*
Roſemary leafed ſweete Ciſtus not hoary.

As the ſmall narrow leaves of the laſt were greene abovē and gray under, ſo this Ciſtus hath them wholly greene, and not gray on the under ſide, but are ſomewhat larger then it, and more thinnely or

ſparſedly

7. *Ciſtus Ledum anguſtis foliis.*
Narrow leafed ſweete Ciſtus.

10. *Ciſtus Ledon Roſmarinis foliis ſubtus non incanis.*
Great Roſemary leafed ſweete Ciſtus.

12. *Myrto Ciſtus Pennæi.*
Dr. *Penny* his Mirtle like Ciſtus.

13. *Ciſtus Ladanifera Cretica vera & Pſudociſti Ledo duo.*
The true ſweet gum Ciſtus of *Candy*, and 2. Baſtard ſorts alſo.

sparsedly set on the dry sapleſſe branches, which are lower then it and more Gummy whereon the flowers stood.

11. *Ciſtus Ledum folio Thimi.* Time leafed sweete Ciſtus.

This Ciſtus beareth small leaves not much unlike Time leaves on the clammy blackiſh small branches, of about a foote high; the flowers hereof were not seene no more then in the laſt, but the heads of this were many standing together upon long footeſtalkes, without any seede in them.

12. *Myrto Ciſtus Pennæi.* Dr. *Penny* his Mirtle like Ciſtus.

The Mirtle like Ciſtus of Dr. *Penny* his finding, is a shrubbe of foure or five foote high, whoſe ſtalkes and branches are covered with a rugged barke, set as it were with knobbes or bunches, which quickly fall away from the elder branches; the leaves are very like Mirtle leaves, and are no leſſe rugged then the barke, yet grow smooth in time, and are set one againſt another at every joynt, bedewed with that sweete clammy moiſture as in others, the flowers are small and yellow, conſiſting of five long leaves, with many yellow threds in the middle, after the flowers are paſt, come somewhat long five square heads with small seede therein.

13. *Ciſtus Ladanifera Cretica vera.* The true sweete Gum Ciſtus of Candy.

Although I sayd in the beginning of the Chapter of male Ciſtus that the male kind onely boare red flowers, and the female white, including the Ledum under them, which as I sayd alwayes bore white flowers, yet this generall rule admitteth some exception, as in this plant I here doe shew you, which groweth in *Candy* moſt abundantly; and from whence alſo onely the *Candiots* gather *Ladanum* as *Bellonius* being there truly obſerved, and not from the other ſorts of *Ledon*; and *Alpinus* saith the same by the relation of others, who hath thus deſcribed it: It groweth to a cubits height or more, with sundry long wooddy branches, with two and ſometimes more leaves ſet thereon together at ſeverall ſpaces one againſt another, being greater then thoſe of the male Ciſtus, some-

Pſeudo-ciſti alij duo.

what like unto Sage leaves, and bedewed very much with that sweete clammy humour or Gum, called *Ladanum* eſpecially in the Summer time, the flowers that grow at the toppes of the branches are like the male Ciſtus, and of a purpliſh colour, but greater then they, after which come small long and round, hard, blackiſh heads, containing small seede within them. *Alpinus* joyneth hereunto two other ſorts of baſtard *Ciſtus Ledum*, the one whereof is not as he conceiveth fit to bee called Ciſtus, having little or no reſemblance to any, having ſlender ſtalkes and branches with a few small long leaves like unto Privet, ſet at certaine long diſtances one from another, with white flowers at their toppes, much leſſer then thoſe of Ciſtus, without any ſent, and small seede in blacke pods afterwards. The other baſtard ſort hath many ſoft ſtalkes with ſoft woolly leaves thereon, in forme like Mirtle leaves or leſſer, two or foure ſtanding at a place by diſtances, the flowers are white and small; the seede veſſels be of the bigneſſe of Ciche peaſe, and the small seede yellow within.

The Place.

All theſe ſorts of Ciſtus grow onely in the warmer countries of *France*, *Spaine*, *Portugall*, *Italy*, *Candy* and the other Eaſterne parts, and not in any of theſe colder countries that ever I could learne: the twelfth Mirtle like Ciſtus Dr. *Penny* a famous Phyſition of *London* in his time, found in the Iſland *Majorca*, and ſhewed to *Cluſius* the dryed plant, which he kept by him, and gave him the deſcription of it, which he publiſhed with the other in print: the laſt and the two baſtard ſorts grow in *Candy*, from whence we had the knowledge of them.

The Time.

All theſe ſorts of sweete Ciſtus doe flower earlier by much in their naturall countries then they doe in ours, for they never are in flower in our countries untill *July* or *Auguſt*, and ſeldome doe give any ripe seede.

The Names.

It is called in Greeke λῆδον *Ledon*, and κάδδον *Ladon*, *quia (forſan) folia non levia aut nitida ſunt, ſed potius ſquabra & pannoſa*, the Latins keepe the Greeke name, and call it *Ledum*, becauſe they all have that clammy sweete humour on them more or leſſe, and *Ladum*, from whence commeth the name of *Ladanum*, which is that sweete gumme is gathered from the leaves and branches of but one ſort as *Matthiolus* and *Ceſalpinus* seeme to avouch, and *Bellonius* averreth in his firſt booke of obſervations and seventh Chap. but others say from many of them, and is moſt uſed now adayes in perfumes to smell unto, and to burne, yet ſometimes Phyſically alſo: the manner of gathering whereof in theſe dayes is some what like one of thoſe wayes was uſed in *Dioſcorides* and *Plinies* times, which was that they uſed to faſten long Ropes, but wee now long Thongs of raw or untanned Leather to a long poale or ſticke made like a Rake, without teeth, which by drawing them over the buſhes, gather that dew or gum that is upon them, and in the heate of the day, and Sun, they ſcrape it from thoſe Thongs, and make it up into balls or lumpes: the other was to combe of that sweete gum from the beards and haunches of the Goates, that browſed and rubbed themſelves on thoſe buſhes that grew in the Iſle of *Cyprus*: the *Arabians* call the tree *Chaſus*, and the gumme *Leden* and *Laden*, the *Spaniards* call the firſt ſort *Xara*, *Xarguna* and *Xaguarca*, and some *Xara eſtepa*, as *Cluſius* saith: but the fourth kind of *Cluſius* which is the fift here, he saith they call *Ardivieja*: all other Chriſtian nations I thinke follow the Greeke and Latine name, with ſuch diverſitie as their Dialect affordeth; wee as I sayd may call it *Ledum* as others doe, or the sweete Ciſtus, or sweete Gum Ciſtus whether you will: it needeth not to make any long repetition of references of every one of theſe ſeeing the moſt of them are *Cluſius* his relations, and may eaſily bee found by any which is which.

The Vertues.

Becauſe all or moſt of theſe sweete Ciſtus are more hot then the former ſorts, yet not leſſe drying and binding then any of them, they are uſed to warme and dry up all cold defluxions of the braine, and *Galen* saith that the gum *Ladanum* is hot in the end of the firſt degree, almoſt entring into the ſecond, and hath some aſtriction alſo in it: furthermore it is of a thinne ſubſtance, whereby it is mollifying and moderately digeſting, and thereby very effectuall in the hardneſſe and other diſeaſes of the mother, to eaſe the paines thereof, and to heale thoſe Vlcers that happen therein; by the taking of the fume thereof underneath, or applying it in the ſubſtance: being made up with *Storax* and honey, in a *Lohoch* or Electuary, it is very profitable for the Cough, if it be old or in the Longs: being taken inwardly it provoketh Vrine, and ſtayeth the laske or flux of the belly, and eaſeth the griping paines thereof proceeding from chollerick ſharpe humours, & is very good for all ſower belchings or riftings: being uſed in an oyntment with Mirrhe, oyle of Mirtles and Wine, it ſtayeth the falling of the haire, and baldneſſe thereupon: it helpeth alſo the paines in the eares, being uſed with some oyle of Roſes: being diſſolved in wine, and the places waſhed therewith that have any ſcarre or deformitie thereon, it doth wonderfully alter the

colour

colour and evill ſight thereof, and maketh them to be well coloured againe: eyther the gumme or the leaves and branches boyled in lye, and the head waſhed therewith doth cleanſe it from ſcabbes, ſcurfe, or dandraffe growing thereon, and cureth alſo old running and watering ſores and Vlcers in the Legges or other parts of the body: the oyle made thereof worketh to the like effects.

CHAP. LXXXVIII.

Hypociſtis. The Vndergrowth or Excreſcence of the Ciſtus.

I Thinke it fitteſt to entreate of this Excreſcence proper onely to the ſorts of Ciſtus by it ſelfe, and not termix it with the hiſtory and deſcriptions of them, or among the other Rapes or excreſſences of other Plants: it is of divers colours according to the kinds of Ciſtus, under which and from whoſe rootes it groweth and ſpringeth as the Broome Rape, and other excreſcences doe from the abounDance of ſuperfluitie of moiſture, cauſing putrefaction; but this is of a peculiar faſhion: It riſeth up (as well from the rootes of the male Ciſtus as female; as alſo from many ſorts of the *Ledum* or ſweete Ciſtus) with divers upright ſtalkes, covered with ſmall leaves thicke ſet thereon (eyther neare or under the ſtemme of the Ciſtus, or ſomewhat further off, in divers places as the rootes doe ſpread) ſcarſe a foote high, having many flowers growing at the toppes full of juice, the whole plant riſing from the male Ciſtus at the firſt ſpringing up, being of an orient bright crimſon colour, but much paler afterwards, and the flowers whitiſh at the laſt, which ſtand many together at the toppes of the ſtalks, are every one faſhioned ſomewhat like unto the buds and flowers of the Pomgarnat tree, or rather like unto the woodden noſſell of a Candleſticke, which paſſe away, leaving ſeede as ſmall as duſt in the hard heads or ſeede veſſells, which are unprofitable to produce the like plant, as the berries of the Miſletoe are, being as it is but an excreſcence, growing as I ſayd from ſuperfluitie of moiſture and putrefaction. That which riſeth from the rootes of the female Ciſtus, eſpecially that with Sea Purſlane leaves, is of a yellow colour. And that which ſpringeth from the *Ledum* or ſweete gum Ciſtus, is of divers colours, being intermixt with purpliſh and greene ſtalkes or veines, in the pale coloured ſtalkes of leaves and flowers, as Cluſius hath obſerved and ſet it downe, but ſuch as *Dioſcorides* relateth to bee ſome white or greene, eſpecially greene hee obſerved not in any.

Hypociſtis. The undergrowth or Excreſſence of the Ciſtus.

The Place.

It alwayes groweth from the rootes of the Ciſtus in the naturall places, and not in any Gardens whereunto they are tranſplanted.

The Time.

It abideth freſh many Winters after it is riſen, but is in its chiefeſt beauty at the Spring, and in his full ſtrength in the beginning of Summer, when is the fitteſt time to gather the juice.

The Names.

It is uſually called in Greeke ὑποκιστις *Hypociſtis*, but *Dioſcorides* ſaith that ſome called it in his time *Rhabethrum* and *Cytinus*. *Cluſius* calleth that kind which groweth on the *Ledum* αἱμόδωρον, *ſive Cynomorij genus*, and *Dodonæus Limodori quoddam genus*: the Latines keepe the Greeke name, and call both the plant and the juice drawne from it *Hypociſtis*: but as *Matthiolus* ſaith the *Arabians* were the cauſe of the errour of the Apothecaries and others in former times; who calling Ciſtus by the name of Goatesbeard, induced them to beleeve that *Hypociſtis* was made of the juice of the rootes of *Tragopogon* called *Barba Hirci*, or Goatesbeard, ſo that ſuch counterfeit *Hypociſtis* was uſually ſold for true, untill they came to underſtand the true *Hypociſtis*, and to gather the juice from it, which is performed two manner of wayes. The beſt way is to expreſſe the juice from the freſh herbe when it is in full ſtrength: the other is to ſteepe the dryed ſtalks and boyle them, which after they are preſſed is to be condenſate (eyther juice or decoction) by evaporation in the Sunne, or by the fire, in the ſame ſort that *Lycium* was wont to be made, as *Dioſcorides* ſaith. *Fuchſius* tooke the *Hypociſtis* to be a *Fungus* or *Muſhrome*, but *Matthiolus* taxeth him for it, and ſheweth how it ſpringeth.

The Vertues.

The hardned juice called *Hypociſtis* is much more binding then any other part of any Ciſtus: it is a moſt certaine, ſure, and ſafe medecine to ſtay all fluxes of blood or humours, that is to ſay the ſpitting of blood, womens extraordinary courſes, the laske and blooddy flux: it is mixed with thoſe things that are applyed to the ſtomacke to ſtay vomitings, and to ſtrengthen it when it is growen weake, as alſo with thoſe things that ſtrengthen the Liver, to be uſed eyther inwardly or outwardly: it is alſo availeable for clammy moiſt humours that fall upon the joynts or ſinewes, thereby cauſing a weakeneſſe of nerves, and a ſolution of them; to uſe this therefore in pilles inwardly doth wonderfully helpe to dry, and binde, and corroborate the parts; it is put into great Antidotes againſt poyſon, and the peſtilence, not for any ſpeciall propertie it hath to reſiſt the venome, but to contemperate

temperate and ſtrengthen the body: it is held to be a very good ſubſtitute for *Acacia*, which all Chriſtian countries doe much want through their owne negligence, for if they would not ſo much affect ſubſtitutes they might have the true but it is binding and drying more then it.

CHAP. LXXXIX.

Iacobæa. Ragwort.

WEe have two ſorts of Ragwort growing wilde with us in many places, but *Cluſius* hath found out ſome other plants which he referreth thereunto, and there are alſo ſome of this ſort growing by the Sea ſide, which I thinke fit to adjoyne to the reſt.

1. *Iacobæa vulgaris major.* The greater common Ragwort.

The greater common Ragwort hath many large and long darke greene leaves lying on the ground, very much rent and torne on the ſides into many peeces, from among which riſeth up ſometimes but one, and ſometimes two or three ſquare or creſted, blackiſh or browniſh ſtalkes three or foure foote high, ſometimes branched, bearing divers ſuch like leaves upon them at ſeverall diſtances unto the toppes, where it brancheth forth into many ſtalkes, bearing yellow flowers, conſiſting of divers leaves ſet as a pale or border, with a darke yellow thrum in the middle, which doe abide a great while, but in the end growing full ripe are turned into downe, and with the ſmall blackiſh gray ſeede carryed away with the winde: the roote is made of many fibres, ſome greater and others leſſer whereby it is firmely faſtned into the ground, and abideth many yeares.

2. *Iacobæa vulgaris minor.* The leſſer common Ragwort.

This Ragwort is very like the precedent, ſo that many that are not skilfull or curious in the obſervation of plants do overpaſſe it, as judging it but the ſame with the former: the chiefeſt differences are theſe; it uſually riſeth not ſo high, the leaves are not ſo finely jagged, nor of ſo ſad a greene colour, but rather ſomewhat whitiſh, ſoft and woolly, and the flowers are uſually paler, yet in many alike.

3. *Iacobæa latifolia Pannonica prima.* The firſt *Hungarian* broad leafed Ragwort.

The firſt leaves of this Ragwort that lye next the roote upon the ground are round almoſt, and larger then thoſe that grow upon the ſtalke, which have many ſmall peeces or jagges at the bottomes of them, whoſe ends are longer and not ſo round, and ſtill more jagged as they grow up higher, and the higheſt moſt jagged, very like unto the higheſt leaves of the Ragwort, yet all of them notched or dented about the edges, at the top of the ſtalke which is about two foote high, breake forth many branches of flowers greater then in the former, but yellow in the ſame manner, and give ſuch ſeede that is carried away with the downe: the roote is great and white, with many fibres, abiding as well as the firſt.

1. *Iacobæa vulgaris.* Common Ragwort.

5. 3. *Iacobæa anguſtifolia & latifolia Pannonica.* *Hungarian* Ragwort of two ſorts.

4. Iacobæa

6. *Iacobæa rotundifolia incana.*
Round leafed hoary Ragwort.

7. *Iacobæa marina sive Cineraria vulgaris.*
The comman Sea Ragwort.

8. *Iacobæa marina altera seu minor.*
The lesser Sea Ragwort.

9. *Iacobæa maritima sive Cineraria latifolia.*
Broadleafed Sea Ragwort.

4. *Iacobæa latifolia Pannonica altera.* The other broad leafed *Hungarian* Ragwort.

This Ragwort is somewhat like the other as *Clusius* saith, but greater, having larger leaves and more pointed, whitish or hoary underneath and with fewer peeces of leaves or eares at the bottome of them, and more finely dented about the edges: the flowers are large and yellow like the other.

5. *Iacobæa angustifolia Pannonica non laciniata.* Smooth leafed Ragwort.

This unjagged Ragwort hath somewhat broad and long leaves, lying next the roote, not jagged or divided at all, but slightly dented on the edges, of a pale greene colour, soft and a little woolly withall: but those that grow on the crested cubit high stalke are narrower and longer compassing it at the foote of them: the highest leaves are smallest and narrowest, where the flowers standing above them are set as it were in a tuft or umbell, foure or five together, which while they are buds, and not blowne open, are of a darke reddish colour, but being blowne open the pale or border of leaves are of a yellowish red or orreng colour on the upperside, and reddish underneath, parted or dented at the ends, the middle thrum being of a faire gold yellow colour, which turne into downe and together with the seede is carried away with the winde: the roote is like the other and continueth also.

6. *Iacobæa rotundifolia incana.* Round leafed hoary Ragwort.

The roote of this Ragwort is browniſh, and composed of long strings as the other sorts are, from whence rise divers thicke and somewhat round leaves, greene on the upperside, but very hairy, and hoary white underneath of two inches long a peece, and an inch and halfe broad, with a short footestalke underneath and dented about the edges: the stalke which is about a foote high, hath but few leaves thereon, and those very narrow and long; at the toppes whereof stand large yellow flowers, like unto the *Scorsonera* or Vipers grasse: the seede hath not beene observed.

7. *Iacobæa marina sive Cineraria vulgaris.* The common Sea Ragwort.

The Ragwort that groweth in our land neare the Sea side, hath hard crested stalkes about two foote high, all hoary or white, whereon grow hoary white leaves, much jagged or cut into divers parts, yet each part, of them broader then any of our wild Ragworts, and somewhat stiffe, but yet soft in handling: the toppes of the stalkes are furnished with divers flowers, whose cups or huskes are hoary as the rest of the plant is, but the flower it selfe is of a pale yellow colour, with a browniſh thrum in the middle, which turne into downe, and with the seede is carryed away with the wind: the root is long and more wooddy then the other, with divers small fibres thereat.

8. *Iacobæa marina altera seu minor.* The lesser Sea Ragwort.

The other sea Ragwort groweth lesser and lower then the former, yet the leaves are longer and much divided, or cut into many jagged leaves, each jagge being rounder pointed then the other, of a grayish or ashcolour greene above, and very white underneath, the flowers are many that grow at the toppes of the hard wooddy hoary white stalkes, which are three or foure foote high sometimes, and branched, but smaller and of a dun or darker yellow then the other, and the middle thrum browner also, which abide in flower two whole months at the least, before they fall away, turning at the last into downe as the other: the roote is somewhat great and wooddy like the other.

9. *Iacobæa maritima sive Cineraria latifolia.* Broad leafed Sea Ragwort.

This Sea Ragwort sendeth from the roote divers round stalkes about a foote and a halfe high, very hoary and woolly, divided into divers branches, the lower leaves whereof are somewhat round and jagged as a Colewort, each part being as it were waved about the edges, and each leafe beinga bout foure inches broad, and a foot long together with the footstalk, of a darke greene colour on the upper side, and hoary white undeneath & soft in handling, the flowers grow at the tops of the branches upon longer and slenderer footestalks, whose cups or husks are hoary, and the flowers themselves greater and paler then in the former sorts, the middle thrum being of a gold yellow colour, which after they are ripe are turned into downe, and with the seede blowne away with the winde.

The Place.

The two first sorts grow wilde in pasture and untilled grounds in many places, and both together in one field oftentimes; the three next grow in *Hungary* and *Austria*, the sixt grew in some parts of *France*, but it is not expressed where, the seventh groweth on our owne coasts, not farre from the Sea, in the Isles of *Sheppie* and *Tennet*, and along the *Kentish* shore in many places: the eighth groweth on the Mediterranean Sea shore of *Italy*, and other places, but *Dodonæus* saith by the Sea side in *Zeland*, the last is not mentioned by *Bauhinus* where it groweth.

The Time.

These flower in *Iune* and *Iuly* and the seede is ripe in *August*.

The Names.

Being an herbe of later knowledge, it is not mentioned by any ancient Greeke or Latine Author, unlesse you would as some doe, referre it to the ἠείγερον, *Erigerum* of *Dioscorides*, which the Latines call *Senetio*, and therefore *Lobel* calleth it *Iacobæa Senetio*. *Tragus*, *Matthiolus* and others call it *Flos Sancti Iacobi*, and *Herba Sancti Iacobi*. *Dodonæus Iacobæa*, *Camerarius* and others *Senetio major*, *Gesner in hortis* calleth the fourth *Hungarian Iacobæa* of *Clusius Conyzæ Alpinæ genus*, and *Conyza montana* in another place. Some have taken the sea kind to be *Arthemisia marina*, or a *species* of it, because the division of the leaves is somewhat like the *Arthemisia vulgaris*, others call it *Cineraria* and *Argentea* from the whitenesse of the leaves which shew like silver, or as though they were covered with ashes, and is usually with us called *Iacobæa marina*, and *maritima*: the first is common as well in other countries as in this: the second is not remembred by any author that I know, unlesse it bee the first *Iacobæa Pannonica* of *Clusius*: the third is *Clusius* his *Iacobæa Pannonica tertia, sive latifolia prima*, as the fourth is his *Iacobæa Pannonica quarta*, and *latifolia secunda*: the fift is his *Iacobæa Pannonica secunda*: the sixt is *Bauhinus* his *Iacobæa latifolia incana*: the seventh is the *Cineraria* of *Dodonæus*, and *Iacobæa marina* of *Lobel*, *Pena*, *Lugdunensis* and others, and the *Athaovanabiat* or *Arthemisia marina*, of *Alpinus lib. de plantis Ægypti*, and *Eruca cinerea* of *Lugdunensis* as *Bauhinus* thinketh, but surely then the figure is farre awry: The eighth is the *Cineraria* of *Lobel*, and is called by most Herbarists *Cineraria altera*, and *Iacobæa altera marina* of *Dodonæus* and *Lugdunensis*: the last is called by *Bauhinus Iacobæa maritima sive Cineraria latifolia*. It is called by the *Italians Senecio maggiore*, *Cardu-*

Carduncello, and *Spelliccioſa maggiore*: by the *Spaniards Bomaron major*: by the *French L'herbe S. Iaques*: by the *Germans* S^t. *Iacobs blumen*, and S^t. *Jacobs craut*: by the *Dutch* S. *Iacobs cruyt*, and *Aſchercruidt*, and we in *Engliſh* S. Iameſwort and Ragwort.

The Vertues.

Ragwort is hot and dry in the ſecond degree as ſome thinke, with ſome bitterneſſe joyned therewith, and therefore clenſeth, digeſteth, and diſcuſſeth: the decoction of the herbe is much commended to waſh the mouth or throat that have Vlcers and ſores therein, and for ſwellings, hardneſſe or impoſtumations, for it throughly clenſeth and healeth them, as alſo the ſquinſie and the Kings Evill: it doth helpe to ſtay catarrhes, thinne rheumes and defluxions from the head into the eyes, noſe or lungs: the juice is found by continuall experience to bee ſingular good, both to heale greene wounds, and to clenſe and heale all old and filthy Vlcers, as well in the privities and in other parts of the body, and inward wounds and Vlcers alſo, and ſtayeth the malignitie of fretting or running Cankers and hollow Fiſtulaes, not ſuffering them to ſpread further: it is much commended alſo to helpe aches and paines either in the fleſhy parts, or in the nerves and ſinewes, as alſo the Sciatica or paine of the hippes or hucklebone, to bathe the places with the decoction of the herbe, or to annoint them with an ointment made of the herbe bruiſed and boyled in *Axungia* or old Hogs Suet, with ſome Maſticke and *Olibanum* in powder added unto it after it is ſtrayned forth and not before as *Gerard* ſaith, for ſo it were to no purpoſe to put them in: it is held alſo to be a certaine remedie to helpe the Staggers in Horſes.

CHAP. LXXXX.

Senecio. Groundſell.

DIoſcorides, *Galen* and *Pliny* and the other ancients have made mention, but of one ſort of *Senecio* or Groundſell, but this later age hath found out divers other ſorts as ſhall be preſently declared; but in that I ſet it here which might elſe have beene placed among the *Intubacea* or *Cichoreacea*, whereof it is a *ſpecies*, it was to joyne it with the *Iacobæa* going before, whereunto it is likeſt in name face and property.

1. *Senecio vulgaris.* Common Groundſell.

Our common Groundſell hath a round greene and ſomewhat browniſh ſtalke, ſpread toward the toppe into ſome branches, ſet with long and ſomewhat narrow greene leaves cut in on the edges ſomewhat like unto Rocket, or rather an Oaken leafe, but leſſer and round at the ends, at the toppes of the ſtalkes and branches ſtand many ſmall greene knappes or heads, out of which grow ſmall yellow threds or thrums which are the flowers, which continue many dayes blowne in that manner before it paſſe away into downe, and with the ſeede is carryed away in the winde: the roote is ſmall and threddy and ſoone periſheth, but from the ſeede that is ſhed it ſoone riſeth up againe, ſo that it may bee ſeene many moneths in the yeare, both greene and in flower and ſeede, for it will ſpring and ſeede twice in a yeare at the leaſt if it be ſuffered in a Garden.

1. *Ssnecio vulgaris.* Common Groundſell.

2. *Senetio montanus.* Mountaine Groundſell.

Of this kind there is another ſort that groweth not altogether ſo high, whoſe leaves are greater and more cut in on the edges, in all things elſe like the ordinary ſort.

3. *Senetio folio non laciniato Myconi.*
Myconus Spaniſh Groundſell.

The leaves that grow upon the hard ſtalkes of this Groundſell are whole and not divided or cut in on the edges as the reſt are, but onely dented like unto Germander leaves, and grow ſingly one above another thereon: the flowers are larger but yellow, and as ſoone fading and turning into downe as the other, the roote is ſaid to be more hard and wooddy.

4. *Senetio incanus ſive Erigerum tomentoſum.*
Cottony Groundſell.

This Cottony Groundſell hath much larger leaves, and more divided or torne on the edges then the other mountaine ſort, of a grayiſh or aſhcolour ſoft and hairy or rather hoary all over: the ſtalkes are higher and greater, but with ſuch like yellow flowers upon them and as ſoone fading and turning into downe almoſt as the other; the roote is ſmall and full of fibres.

5. *Senetio fœtidus.* Stinking Groundſell.

This ſtinking Groundſell hath many faire large and long leaves lying next the ground very much cut in on the edges into many diviſions, ſomewhat like unto thoſe of Mugwort, whereupon ſome have called it *Arthemiſia fœtida*, but ſoft, and in handling very hairy, bedewed with a fattie clammineſſe, ſo that the leaves will ſticke to the fingers of them that touch them, and one leafe alſo unto another, hardly to be pulled aſunder, ſmelling ſomewhat ſtrong and of an ill ſent, (not unpleaſantly

3. *Senetio folio non laciniato Myconi.*
Miconus Spaniſh Groundſell.

5. *Senetio fœtidus.*
Stinking Groundſell.

ſaith *Cluſius*, but as others ſay like *Scrophularia* or *Ebulus*; from among which riſe up hairy creſted ſtalkes, about a foote and a halfe high, divided into ſundry branches, bearing at the toppes fewer flowers, leſſer and of a paler yellow colour then the common ſort, and upon longer footeſtalkes, which quickly fade and turne into downe like the other: the roote is very fibrous yet laſteth not after ſeede time, but periſheth as the firſt doe, and ſpringeth againe of the ſhed or fallen ſeede.

6. *Senetio odoratus.* Sweet ſmelling Groundſell.

This Groundſell is ſomewhat like the laſt ſort in the ſoft and woolly leaves, but not ſo much torne on the edges as it, whoſe ſmell is ſomewhat ſweete like unto *Ambroſia*, or Oake of *Cappadocia*, or the middle *Coniza* or Fleabane, the flowers are like the reſt, and as ſoone growing old and hoary as downe.

The Place.

The firſt is found every where almoſt, as well on the toppes of walls as at the foote among rubbiſh, and in untilled grounds but eſpecially in Gardens; the ſecond is found upon hills and mountaines: the third was found by *Myconus* in *Spaine* and ſent to *Lyons*: the fourth groweth by wood ſides, the borders of fields, and upon old walls in many places: the fift groweth in lopped woods of *Hungaria* and *Auſtria*, as *Cluſius* ſaith, and in barren and untilled places: the laſt was ſent to *Camerarius* out of *Italy*.

The Time.

The time of the firſt to be in flower is already ſet downe in the deſcription, which is almoſt every Moneth: the ſecond and fourth doe both come ſomewhat neare unto the other, but are not ſo quicke in their decaying: the fift and ſixt doe flower onely in Summer.

The Names.

It is called in Greeke ἠεἰγερων *Erigerum quia vere ſeneſcit*: the Latins call it *Senetio, quia cito ſeneſcit*. *Tragus* tooke it to be the *Aphaca* of *Theophraſtus*, in his ſeventh booke and ſeventh and eighth Chapters, eſpecially the cottony kind, which is more bitter and called *Petrella* by *Manardus Ferrarienſis*, as he ſaith, numbring it among the *Intubacea* or *Cichoreacea*, the Succory like herbes, which it doth in ſome ſort well reſemble for the manner of flowring and periſhing: but I finde in the ſeventh and eighth Chapters of his ſaid ſeventh booke, *Senecio* named as well as *Aphaca*, which plainely convinceth *Tragus*, that *Senecio* cannot be *Aphaca*, for there they are ſet downe for two herbes: and beſides *Dalechampius* in *Lugdunenſis* hath given us an *Aphaca* among the other *Cichoreacea*, even the *Hedipnoïs ſive Cichorium flore luteo Dodonei*: *Simon Ianvenſis* tooke it to be *Cardnus benedictus*, and *Brunfelſius* to be *Verbena*, but *Tragus* refuteth the one and *Matthiolus* the other: the *Italians* call it *Cardoncello Senecione*, and *Speliccioſa minore*: ſome alſo for the often flowring of it *Fior di ogne meſe*: the *Spaniards* call it *yerva can*, *Cardo monto*, and *Bonvaron*: the *French Seneſſon*: the *Germans Creutzwurtz*: the *Dutch Cruizcruyt*, and wee in *Engliſh* Groundſell and Grunſell: The firſt is called by all Authors *Senetio*, and *Senecio* (and minor with ſome, becauſe as I ſaid they call the *Iacobæa Senecio major*) & *Erigerũ*; ſome alſo after the *Italian* name *Carduncellus*, which I verily beleeve, ſhould be that herbe was appointed to be put into the compoſition of the *Unguentum Marciatum*,

tum, and not *Cardus Benedictus*, as it is appointed in the *Pharmacopœia Londinenſis*: the ſecond is the *Senecio 2. vel montanus* of *Tabermontanus* and the firſt *Erigerum* in the old *Gerard* very well expreſſing it: the third is ſet downe by *Lugdunenſis* under *Miconus* name: the fourth is the ſecond *Senecio* with *Tragus*; *Lobel* his figure of *Erigerum tomentoſum*, as alſo the *Erigerum tertium* of *Dodonæus*, as not the true figures of this plant, as *Dodonæus* himſelfe acknowledgeth, but rather as others called it *Cichorium fœtidum*, and *Lugdunenſis* hath obſerved it likewiſe; for this differeth chiefly from the common ſort but in the hoarineſſe and largeneſſe as well of the whole plant as of the leaves: the fift is called by *Lobel Erigerum tomentoſum alterum*, by *Thalius Erigerum fœtidum ſeu majus*, by *Geſner in hortis* and by *Lugdunenſis Senecio fœtidus*, by *Cluſius Iacobæa Pannonica prima* as *Bauhinus* thinketh, & by him *Senecio incanus pinguis*: the laſt is mentioned onely by *Camerarius in horto*, who ſaith he received it by the name of *Senecio flore odorata* from *Ioſephꝰ de Caſa bona*, the great Duke of *Tuſcane*, or *Florence* his Herbariſt.

The Vertues.

Groundſell is cold and moiſt as *Tragus* ſaith, and therefore ſeldome uſed inwardly. *Galen* ſaith in *6. ſimpl.* it hath a mixt quality both cooling and a little digeſting: the decoction of the herbe ſaith *Dioſcorides*, made with wine and drunke helpeth the paines in the ſtomacke proceeding of choller (which it may well doe by a vomit, which our daily experience ſheweth, the juice hereof taken in drinke, or the decoction of the herbe in Ale gently performeth) *Pliny* addeth from others report that it is good againſt the Iaundies and falling ſickneſſe, being taken in wine, as alſo to helpe the paine of the bladder, that is in making water when it is ſtopped, which it provoketh, as alſo to expell gravell in the reines or kidneyes, a dram thereof given in *Oxymel*, after ſome walking or ſtirring the body: it helpeth the Sciatica alſo and the griping paines in the belly, or the Collicke: ſome alſo eate it with Vinegar as a Sallat, accounting it good for the ſadneſſe of the heart, and to helpe the defects of the Liver: it is ſaid alſo to provoke womens courſes, and ſome ſay alſo that it ſtayeth the whites, which as *Matthiolus* ſaith cannot be beleeved to be ſo, in that the one quality is contrary to the other: The freſh herbe boyled and made into a Poultis, and applyed to the breaſts of women that are ſwollen with paine and heate, as alſo to the privy parts of man or woman, the Seate or Fundament, or the Arteries, Ioynts and Sinewes, when they are inflamed and ſwollen doth much eaſe them; and uſed with ſome ſalt helpeth to diſſolve the knots or kernells that happen in any part of the body: the juice of the herbe or as *Dioſcorides* ſaith, the leaves and flowers with ſome fine Frankinſence in powder, uſed in wounds, whether of the body or of the nerves and ſinewes doth ſingularly helpe to heale them. The downe of the heads ſaith hee uſed with Vinegar doth the like, but if the ſame downe be taken in drinke it will choake any: the diſtilled water of the herbe performeth well all the aforeſayd properties, but eſpecially for the inflammations of the eyes, and watering of them, by reaſon of the defluxion of the rheume into them. *Pliny* reporteth a ridiculous fable to helpe the toothach, to digge up the plant without nny Iron toole, and then to touch the aking tooth five times therewith, and to ſpit three times after every ſuch touch, and afterwards to ſet the herbe againe in the ſame place, ſo that it may grow will eaſe the paines: another as fabulous and ridiculous as that, is this, which ſome have ſet downe, that glaſſe being boyled in the juice of Groundſell, and the blood of a Ramme or Goate, will become as ſoft as wax, fit to bee made into any forme, which being put into cold water will come to be hard againe.

CHAP. XCI.

Tripolium. Sea Starrewort.

ALthough *Dioſcorides* and *Galen* knew but of one *Tripolium*, yet becauſe *Lobel* hath ſet forth another that is leſſe, and *Camerarius* accounteth another herbe alſo to be a little ſort thereof, I thinke it not amiſſe to make mention of them alſo in this place, and ſome others of later knowledge.

1. *Tripolium majus ſive vulgare.* The greater Sea Starrewort.

Our ordinary Sea Starrewort hath many long and ſomewhat broad leaves, riſing from the roote next the ground, ſmooth, fat and thicke, and of a blewiſh greene colour, ſomewhat like unto the leaves of *Dorias* Woundwort, but much leſſer, from among which riſeth up a ſmooth herby or fleſhy greene ſtalke, two or three foote high, branched towards the toppes into divers ſmaller branches, with ſuch like leaves on them as grow below but leſſer: the flowers that ſtand at the toppes of them are ſomewhat larger and greater then of the other *Italian* Starrewort, here before ſet forth among the *Aſters* and almoſt of the ſame colour, having a blewiſh purple border of leaves ſtanding about a yellow middle thrum, which after it hath done flowring, turneth into downe, and the ſmall ſeede therewith is blowne away at the will of the winde: the roote hath divers greater ſtrings, and many ſmaller fibres thereat, which grow deepe and ſticke faſt in the mudde of the marſhie ditches where it groweth.

2. *Tripolium minus.* The leſſer Sea Starrewort.

The ſmall Sea Starre is in all things like the greater, but leſſer and lower, both in roote, leafe ſtalke and flower, and in the naturall places obſerved not to exceede the greatneſſe of the ſmall *Conyza* or Fleabane.

3. *Tripolium minus Germanicum.* Small Sea Starrewort of *Germany*.

This alſo is very like unto the laſt, but leſſe then it, having a ſhorter ſtalke and narrower leaves, the flower alſo is ſmall and of a more purpliſh colour.

Lobel maketh mention that *Moutonus* had in his Garden one hereof with yellow flowers, but I rather thinke it was another kinde of herbe, and therefore I make no further mention of it here.

4. 5. *Tripolium Lychnidis Coronariæ folio & alterum Ferulæ folio.* Starrewort with Roſe Campion like leaves, and another with Fennell like leaves.

The ſeede of both theſe ſorts of Starreworts I received from Signor *Boel* from *Liſbone*, but they ſprang not with me: but it may be that with Fennell like leaves was the *Ageratum ferulaceum* of *Lugdunenſis*.

The Place.

The firſt groweth as I ſayd before in the ditches of the ſalt Marſhes, neare the Sea coaſts in many places of this Land, ſo that you ſhall hardly miſſe it in any ſalt Marſh in ſome place or other if you looke well for it: the ſe-

cond groweth as *Lobel* ſaith neare the mouth of the River *Poo*: the third ſaith *Cordus* groweth in the ſalt Marſhes that are nigh unto the Lake of brackiſh water, which is by *Staffurt* in *Germany*, and ſo doe the other two as hee ſaith alſo.

The Time.

They flower in *Iune* and *Iuly* for the moſt part.

The Names.

It is called in Greeke τευτόλιον *Tripolium*, which name the Latines keepe and change not, and as *Dioſcorides* relateth was ſo called, becauſe the flowers did change their colours three times a day, which was but a falſe information or a negligent conſideration. *Serapio* called it *Turbith*, but *Lobel* and *Pena* diſprove it, as I ſayd before in the Chapter of *Tithymales* or Spurges: for the roote of this purgeth not ſay they, either the juice or decoction: *Pliny* in miſtaking *Tripolium* maketh *Polium* to have the ſame facultie, that *Theophraſtus* in his ninth Booke and 21. Chap. giveth to *Tripolium*: and *Gaza* following *Pliny* his errour, tranſlateth it *Polium* alſo; the firſt is called *Tripolium* of all that have written thereof, except *Cordus*, who in *Obſervationum ſylva* calleth it *Anthyllis major*, as he doth the ſecond *Anthyllis minor*, and the laſt *Anthyllis brevior*, and *Columna* who calleth the firſt *Amelli ſpecies paluſtris*, as *Lobel* before him gave him the occaſion, who ſaith it doth more ſignificantly expreſſe the *Amellus* of *Virgil*, then that *Aſter Italorum*, or *montanus purpureus* which we doe account to be it: yet I may ſay by *Lobels* leave, that the *Aſter* before ſaid doth more properly grow *prope flumina* as *Virgil* ſaith his *Amellus* doth, then in *aquis vel ſcrobibus* as *Tripolium* doth.

The Vertues.

Dioſcorides ſaith that the roote is ſwēete in ſmell, and hot in taſte, that two drammes thereof given in wine to drinke purgeth the belly, (which as is before ſayd *Pena* and *Lobel* doe deny) from watery humours, and by Vrine. *Galen* ſaith the roote is ſharpe in taſte and hot in the third degree. *Dioſcorides* further addeth that it is put into Antidotes againſt venome and poyſon. It is found by later experience to be ſingular good to heale all freſh wounds, the leaves onely bruiſed and bound to the place, or the juice dropped into them; as alſo for other hurts or inward bruiſes, and as effectuall alſo as any other wound herbe almoſt whatſoever, for any old Vlcers or ſores.

1. *Tripolium vulgaris.* Sea Starrewort.

CHAP. XCII.

Verbena. Vervaine.

THis herbe hath bred much doubt among many of our moderne writers, what it ſhould be that *Dioſcorides*, *Galen* and *Pliny* make mention of, ſome ſuppoſing one herbe, ſome another, as you ſhall heare by and by; but unto thoſe two ſorts that *Dioſcorides* ſpeaketh of, and *Pliny* calleth *mas* and *famina*, and others *recta* and *ſupina*, wee are to adde one or two more knowne in theſe later times, and ſet forth by ſome.

1. *Verbena mas ſeu recta & vulgaris.* Common or upright Vervaine.

The common Vervaine that is familiar to our Countrey hath divers ſomewhat long and broad leaves next the ground, deepely gaſht at the bottome of them, the other part being deepely dented about the edges, and ſome onely deepely dented, or cut all alike, of a blackiſh greene colour on the upperſide, and ſomewhat gray underneath: the ſtalke is ſquare and branched into divers parts, riſing to bee about two foote high, eſpecially if yee put thereto the long ſpike of flowers at the toppes, which are ſet on all ſides thereof one above another, and ſometimes two or three together, being ſmall and gaping, of a purpliſh blew colour, and white intermixt; after which come ſmall round ſeede, in ſmall and ſomewhat long heads: the roote is ſmall and long and of no uſe.

2. *Verbena ſupina ſive famina.* Bending or female Vervaine.

This other Vervaine hath divers ſmaller and weaker ſquare ſtalkes, leaning or bending downe to the ground, and almoſt lying thereon, not ſtanding upright like the other, parted into many more and ſmaller branches, and having ſuch like leaves growing on them at the ſeverall joynts, but much ſmaller, and more divided or cut in, making them ſeeme to be many leaves, ſet on both ſides the middle ribbes, of a grayiſh greene above and more gray underneath: the flowers grow in the ſame manner that the other doth, in ſmall long ſpikes, being of a deeper blew colour then the other, otherwiſe in forme not unlike: the ſeeds that follow is like it alſo and ſo is the roote, both periſhing after ſeede time, and raiſing it ſelfe of its owne ſowing.

3. *Verbena Peruana.* Vervaine of *Peru*.

This Vervaine is like unto the laſt Vervaine, but growing greater, and abiding greene in Winter as well as Summer, as many of thoſe Accidentall plants doe, which will not in theſe European parts, yea it hath beene obſerved

ſerved that thoſe plants that naturally abide not greene a Winter in theſe parts, being carried thither have conti ued greene all the Winter, contrary to their courſe here.

4. *Verbena repens nodiflora.* Round headed Vervaine.

Th: round headed Vervaine hath from a ſmall fibrous roote a ſmall ſquare, ſmooth trayling joynted ſtalke, whereat grow ſmall leaves almoſt round, yet pointed at the ends, and dented from the middle of them forwards, at each joynt alſo with the leaves come forth other ſmall branches, and a bare ſmall ſtalke, bearing at the toppes a ſcaly round head, from whence ſtart forth ſuch like ſmall flowers as are in the other ſorts, and ſuch like ſeede alſo following them.

The Place.

The firſt groweth generally throughout the Land in divers places, by the hedges and way ſides, and other waſte grounds: the ſecond is not found in our Land, although *Gerard* ſaith ſo, for it will not indure a Winters blaſt before it ſeede with us: the third is of the Weſt *Indies*, and the laſt is naturall of *Naples*.

The Time.

The firſt flowreth about *July*, and the ſeede is ripe ſoone after, and ſo doth the laſt ſometimes; but the other as I ſayd doth ſeldome flower before the Winter with us, and therefore cannot bring his ſeede to perfection, for in the naturall places it flowreth not untill the end of *July*, and in *Auguſt*.

The Names.

It is called in Greeke ἱερὰ βοτάνη *Hiera botane, id eſt, herba ſacra*, and περιστερεὼν *Periſtereon quod Columbæ in ea libenter verſantur*, and *ſacra herba teſte Plinio, quod ea olim apud Romanos domus purgabuntur, familiæ luſtrabantur, Iovis menſa ad ſacrificium & epulas verrebatur, & faciolis in ſacris legationibus illa coronabatur, vel ut Dioſcorides inquit, quod in expiationibus ſuſpenſa, & illi-*

1. *Verbena vulgaris.*
Common Vervaine.

2. *Verbena ſupina ſeu fœmina.*
Bending or female Vervaine.

4. *Verbena repens nodiflora.*
Round headed Vervaine.

gatur mire utilis sit. It was also called *Sagminalis herba, hoc est gramen vel herba ex arce, cum sua terra a Consule evulsum, quod in pacis bellique ritibus habebatur, & Sagmina in publicis remedijs fuere adhibita.* It is called in Latine *Verbena quasi Herbena*, or *herba bona*, *Matricalis*, *Verbenaca*, and *Columbaria*, or *Columbaris*, or *Columbana*, *Exupera*, *Martialis*, and *Herculania*, as also *Ferraria* from the *Germane* word *Eisencraut*, or *Eisenhert*, as I take it. The *Italians* call it *Berbena* and *Verminacola*, the *Spaniards Urgebaom*, the *French Verveine*, the *Dutch Isencruijt*, and *Iserhart*, and wee in *English* Vervaine, and in some countries Pigeons grasse, and Holy herbe, as also in others *Mercuries* moist blood, and *Iuno's* teares. These two first sorts of Vervaine have beene much controverted, as I sayd before by the later Herbarists, and writers, some doubting whether they should be any peculiar herbes, in that they thinke that any grasse or herbe that was cast on the Altar, was called *Verbena*, and for it they alledge *Terence* in *Andræa*, where he saith *Ex ara Verbenas hinc sume*, wherein *Terence* speaketh after his countrey phrase (for *Menander* hath Myrtles, out of whom this was translated) and understandeth such herbes as lay there, and not Vervaine onely. Some also as *Fuschius* and *Tragus* make *Erysimum vulgare sive Irio* to be Vervaine: *Gesner* as *Tragus* saith called one kind of *Prunella*, *Verbena*; and *Tragus* himselfe maketh his third *Verbena supina* to be the *Cannabina aquatica folio tripartito*. *Dodonæus* formerly made the two sorts of wilde Germander to be the *Hiera botane*, *mas*, and *fœmina*, and *Cæsalpinus* tooke the *Sideritis prima Matthioli*, or *Marrubium aquaticum*, to be *Verbenæ alterum genus*, who also called it *Verbena fœmina*, which all others call *mas* and *recta*, for the *supina* is called *fœmina* by them all.

The Vertues.

Vervaine is hot and dry, bitter and binding, and is an opener of obstructions, clenseth and healeth: for it helpeth the yellow Iaundies, the Dropsie and the Goute, as also the defects of the Reines and Lungs, and generally all the inward paines and torments of the body: the leaves being boyled and drunke, the same is held to be good against the bitings of Serpents and venemous beasts, and the Plague or Pestilence, against both *tertian* and *quartane* Agues, killeth and expelleth the Wormes in the belly, and causeth a good colour in the face and body, strengthneth as well as correcteth the diseases of the Liver and Spleene, is very effectuall in all the diseases of the Stomacke and Lungs, as Coughes, shortnesse of breath and wheesings, and is singular good against the Dropsie, to be drunke with some Piony seedes, bruised and put thereto, and is no lesse prevalent for the defects of the Reines and Bladder, to clense them of that viscous and slimy humour which ingendreth the stone, and helpeth to breake it being confirmed, and to expell the gravell: it consolidateth and healeth also all wounds, both inward or outward, and stayeth bleedings, and used with some honey, healeth all old Vlcers, and Fistulaes in the Legs or other parts of the body, as also those Vlcers that happen in the mouth, or used with old Hogs grease, it helpeth the swellings and paines of the secret parts of man or woman, as also for the piles or hemorrhoides: applyed with some oyle of Roses and Vinegar unto the forehead and temples, it helpeth to ease the inveterate paines and ache of the head, and is good also for those that are fallen into a frensy: the leaves bruised or the juice of them mixed with some Vinegar, doth wonderfully clense the skinne, and taketh away all morphew, freckles, pustulaes, or other such like inflammations, and deformities of the skinne in any part of the body: The distilled water of the herbe when it is in his full strength, dropped into the eyes, clenseth them from filmes, clouds or mist that darken the sight, and wonderfully comforteth the opticke veines. The said water is very powerfull in all the diseases aforesayd, eyther inward or outward, whether they bee old corroding sores, or greene wounds. The female Vervaine is held to be the more powerfull for all the purposes before spoken of; but that of *Peru* goeth farre byond them both, for *Monardus* reporteth divers very admirable cures which that herbe hath performed in the *West Indies*; as of a certaine noble woman, who having used the helpe of divers Physitians in vaine, an *Indian* Physitian very skilfull in herbes, gave her the juice of that Vervaine to drinke with some Sugar mixed therewith, for to allay somewhat of the bitternesse thereof, by whose use shee avoided in a few dayes a thicke long worme (which shee called a snake) being hairy, of a foot in length, and double forked at the taile, after which shee grew well; the same noble woman commended the same medicine to another noble woman in *Peru*, who had not beene well of a long time, who having taken it in the same manner for certaine dayes, avoided many small and long wormes, and among the rest, one very long, like unto a long white girdle, after which time shee became well againe. Which medecine was by advice given to many others that complained of Wormes, and they were all soone holpen by avoyding wormes, either more or lesse, and some also roules or balls of haire, and other things: it is held also to bee no lesse effectuall against all poyson, and the venome of dangerous beasts and serpents, as also against bewitched drinkes or the like. Many other examples of cures *Monardus* setteth downe which are too long here to recite, seeing these are sufficient to shew how prevalent that herbe is for many diseases.

CHAP. XCIII.

Hedera terrestris. Ground Ivie or Alehoofe.

VNto the common Ground Ivie, which is not found to vary with us, yet observed by others, to yeeld some differences, I must adde another sort set forth by *Lobel*, which agreeth very well thereto in the face and outward forme, whatsoever it doe in the inward qualities.

1. *Hedera terrestris vulgaris.* Common Ground Ivie or Alehoofe.

This common and well knowne herbe lyeth, spreadeth, and creepeth upon the ground, all about, shooting forth rootes at the joynts of the cornered tender stalkes, set all along with two round leaves at every joynt, somewhat hairy and crumpled as it were, and unevenly dented about the edges, with round dents: at the joynts likewise with the leaves toward the ends of the branches come forth hollow long flowers, gaping at the ends, of a blewish purple colour, with small white spots upon the Label or lippes that hang downe, as also in the mouth or jawes: the roote is small with fibres.

2. *Hedera terrestris minor.* The lesser Alehoofe.

The lesser Alehoofe is altogether like the former sort, but that the trayling branches creepe not so farre about, being

being ſhorter, and growing ſomewhat more upright: the leaves alſo are ſomewhat ſmaller, and the flowers of a paler blew colour.

3. *Hedera terreſtris montana.* Mountaine Alehoofe.

As the laſt Alehoofe was ſmaller then the ordinary ſort is, ſo this is larger in all the parts thereof, as branches, leaves and flowers, the leaves alſo being more rough and hairy, and the flowers of a deeper purple colour.

4. *Hedera terreſtris ſaxatilis Lobelij.*
Stone Alehoofe.

The Stone Alehoofe creepeth alſo and ſpreadeth with his ſlender weake branches, all about upon the ground, with ſuch like round leaves, ſet at the joynts by couples, as in the former, but larger, and more unevenly dented or rather waved at the edges: the flowers that ſtand at the joynts with the leaves, are larger and longer, and of a paler purpliſh colour then the former.

The Place.

The common kind is found under the hedges, and ſides of fields and ditches, under houſe ſides, and in ſhadowed lanes, and other waſte grounds in every part of the Land almoſt: the ſecond is found at the feete of old trees in ſome countries of *Germany*: the third is found to grow on hills and mountaines: the laſt in *Narbone*, and *Provence* in *France*, and in ſome places of *Summerſetſhire*, as *Lobel* quoted it among his papers which came to my hands.

The Time.

They flower ſomewhat early, and abide ſo a great while, the leaves keeping their verdure unto the Winter, and ſometimes abiding if it be not too vehement and ſharpe.

The Names.

It is thought to be the χαμαικισσος *Chamæciſſos* of *Dioſcorides* although there be ſome doubt in the Text, by the tranſpoſition of a letter, and the reſemblance, both which are eaſily reconciled, and this plant by the opinion of the moſt judicious is accounted the true and right *Chamæciſſos* of *Dioſcorides*, no other being found that can come ſo neare it in face and propertie, beſides the neareneſſe of the name, for the Latines *Hedera humilis* is the ſame with *Chamæciſſos*, and *Hedera terreſtris* is not farre from it. Some call it *Corona terræ*, becauſe it ſpreadeth and is like a Garland upon the ground. All writers generally call it *Hedera terreſtris*, yet *Cordus* in his hiſtory of Plants calleth it *Chamæ clema*, and *Brunfelſius* miſtaking it, made it his fourth *Elatine*. *Lugdunenſis* out of the *Geoponickes* calleth it *Malacociſſos, id eſt, mollis hedera*, which moſt properly agreeth unto this, and ſome alſo call it *Hedera plumiatica*, but for what cauſe I know not. *Lobel* calleth the laſt *Aſarina aut Hederula ſaxatilis*, and *Aſarina ſterilis Savena*, and *Narbonenſis agri*. The *Arabian Serapio* putteth it under *Cuſſus* the Ivie, and calleth it *Cacos*. The *Italians Hedera terreſtre*, the *French Lierre terreſtre*, the *Germans Gundelreb*, or *Grundereb*, that is *humi repens*, the *Dutch Onderhaue* and wee in *Engliſh* according to the ſeverall countries appellations, Gill creepe by the ground, Catsfoote, Haymaides, and Alehoofe moſt generally, or *Tunnehooſe*, becauſe the countrey people uſe it much in their Ale, and ground Ivie as frequently although *Lobel* judgeth the *Hedera helix*, or barren Ivie, more properly to deſerve that name as you ſhall heare by and by.

1. 3. *Hedera terreſtris & montana.*
Common and mountaine Alehoofe.

The Vertues.

Ground Ivie is quicke, ſharpe, and bitter in taſte, and thereby is found to be hot and dry, it openeth alſo, clenſeth and rarefieth. It is a ſingular good wound herbe for all inward wounds, as alſo for exulcerated Lungs or other parts, either by it ſelfe or with other the like herbes boyled together, and beſides being drunke by them that have any griping paines of windie or chollericke humours in the ſtomacke, ſpleene or belly, doth eaſe them in a ſhort ſpace: it likewiſe helpeth the yellow Iaundies by opening the obſtruction of the Gall, Liver and Spleene, it expelleth venome or poiſon, and the Plague alſo: it provoketh Vrine and womens courſes, and ſtayeth them not as ſome have thought, but the decoction of the herbe in wine being drunke for ſome time together by them that have the Sciatica or Hippe Goute, as alſo the Goute in the hands, knees, or feete, helpeth to diſſolve and diſperſe the peccant humours, and to procure eaſe: the ſame decoction is excellent good to gargle any ſore throate or mouth, putting thereto ſome Honey and a little burnt Allome, as alſo to waſh the ſores and Vlcers of the privy parts in man or woman; it ſpeedily healeth greene wounds being bound thereto: and the juice boyled with a little honey and Vardigreſſe doth wonderfully clenſe fiſtulaes, and hollow Vlcers, and ſtayeth the malignitie of ſpreading or eating Cancers and Vlcers: it helpeth alſo the itch, ſcabbes, wheales, and other eruptions or exulcerations in the skinne in any part of the body: the juice of *Celandine*, field Daiſies and ground Ivie clarified, and a little fine Sugar diſſolved therein, dropped into the eyes is a ſoveraigne remedy for all the paines, redneſſe, and watering of the eyes, the pinne, and webbe, skinnes or filmes growing over the ſight, or whatſoever might offend them: the ſame helpeth beaſts as well as men: the juice dropped into the eares doth wonderfully helpe the noyſe and ſinging of them, and helpeth their hearing that is decayed. The country people doe much uſe it, and tunne it up with their drinke, not onely for the eſpeciall good vertues therein, but for that it will helpe alſo to cleare their drinke; and ſome doe affirme that an handfull put into drinke that is thicke, will cleare it in a night, yea in a few houres ſay they, and make it more fit to be drunke.

CHAP. XCIIII.

Hedera. Ivie.

THe Ancient Greeke and Latine writers of herbes, as *Dioscorides*, *Theophrastus* and *Pliny* have set downe many varieties of Ivie, (besides the *Hedera spinosa* which is *Smilax aspera* described before in this worke) which were observed in their times, partly in the leaves and flowers, but chiefely in the berries, yet make but three principall kinds, *alba*, *nigra* and *helix*, and yet more exactly two sorts, *una quæ in altum attollitur*, and *alia quæ humi repit*, which division as most proper, they subdivided each of them againe into their *species* or sorts, whereof we know but few, for that onely which climeth upon trees, walls, &c. and beareth black berries, and the other barren kind that creepeth upon the ground, yet with the clasping branches will take hold of whatsoever is next unto it, are best knowne to us; the others with white or yellow berries are seldome seene in these Christian parts, yet I will shew you in this Chapter those diversities that *Theophrastus* speaketh of which they had in former times, joyning thereto some later found out kinds.

1. *Hedera arborea sive scandens & Corymbosa nigra.* The ordinary Climing Ivie.

The climing Ivie groweth up with a thicke wooddy trunke or body, sometimes as bigge as ones arme, shooting forth on all sides many wooddy branches, and groweth sometimes alone by it selfe into a pretty bush or tree, as *Lobel* saith he saw such in this countrey, but usually climeth up by trees, and as the branches rise sendeth forth divers small rootes into the body, or branches of the tree whereby it climeth up, or into the chinkes or joynts of stone walls, whereon it runneth so strongly, fastning them therein, that it draweth the nourishment out of the tree and thereby killeth it by consuming the life and moisture thereof, and by choaking it with the abundance of shadow and moysture of his branches, and evergreene leaves (which may seeme to be an ornament thereto when it is leafeless, but is in the end the bane and utter ruin of it) which branches also having thus fastned their rootes into the tree or wall will live thereby upwards, if any shall cut away the trunke or body below, as well as if it were not taken away at all, but by fastning the roots into the wall, and there growing great, they often so cracke it that it will in time also ruine it utterly: while the tree is young the leaves of most will be cornered, but when it groweth elder, it hath no corners on the sides, and onely round or somewhat longe, and pointed at the end, the young leaves that spring forth from the branches, keeping oftentimes the same order, and are of a darke shining greene colour above, and somewhat of a yellowish greene underneath; striped with white and sometimes with red spots, abiding fresh and greene Winter and Summer: from the joynts of the stalkes and toppes of the branches, grow forth upon short stalkes small mossie yellow flowers, standing in an umbell or close round tuft; after which come small round berries, greene untill they grow ripe, and then turning blacke, with a small point at the end of every one, in which is contained usually foure seedes three square in a manner, but

1. *Hedera arborea nostras.* Our ordinary Ivie.

3. *Hedera Dionysias sive Chrysocarpos.* Yellow berried Ivie.

rund

round on the one ſide. It yeeldeth in the hot countries a kind of reddiſh Gum of a ſtrange ſent which is dangerous to be uſed in Phyſicke inwardly, being cauſticke or burning, but is uſed for outward remedies chiefly.

2. *Hedera corymboſa alba*, White berried Ivie.

This Ivie groweth in the ſame manner that the other doth, without any great diverſitie that hath beene obſerved in our time, and is cheefly diſtinguiſhed in that the leaves are thinner and finer, and of a lighter greene colour, and the berries of a whitiſh or grayiſh colour, and not blacke when they are ripe.

3. *Hedera Dionyſias ſive Chryſocarpos.* Yellow berried Ivie.

The leaves of this Ivie are ſeldome cornered on the edges, but ſmooth, and onely pointed at the ends, of a freſher greene colour, or not ſo blacke as the firſt, thicker alſo and fuller of veines, and more thinly or ſparſedly growing on the branches: the berries are greater then in others, and of a gold yellow colour, declining to bee more browne when they are ripe.

4. *Hedera helix*. Barren Ivie.

The barren Ivie ſendeth forth divers ſlender weake wooddy branches, trayling upon the ground, and for the moſt part lying thereon; but ſometimes it is found to winde it ſelfe, and clime up the buſhes and hedges under which it groweth, with the ſmall tendrells it ſhooteth forth at the ſeverall joynts of the branches, where the leaves come forth, being ſomewhat leſſer then the former, and of a darken ſhining greene colour, uſually formed into three corners, yet ſometimes into five: & at the joynt with the leafe underneath, thruſt forth alſo ſmall white fibres or rootes, whereby it taketh hold as it creepeth: this beareth neither flowers nor ſeede.

5. *Hedera trifolia Virginenſis*. Trefoile Ivie of *Virginea*.

The rootes of this plant doe ſhoote undergrounde, and

4. *Hedera Helix*. Barren Ivie.

5. 6. *Hedera Virginenſis trifolia & quinquefolia.* *Virginean* Ivie of three and five leaves.

7. *Hederaceis foliis planta Lobelij.* *Lobels* Ivie leafed plant.

ſand

ſend forth young wooddy ſtalkes whereof ſome will ſtand upright, others lye downe and take roote againe as they ſpread, as alſo in any wall they ſtand nigh unto, like unto our barren Ivie: the leaves are broad and large, three alwayes ſet together upon a long footeſtalke: at the joynts with the leaves come forth the pale flowers in a looſe tuft or cluſter, which turne into pale yellow berries, with ſmall, hard, round aſhcoloured ſeede in the dry wrinkled skinne or huske, without any moiſture at all in them, this plant yeeldeth a white milke without any taſte, being broken in any part thereof, which after it hath abidden a while will change to bee as blacke as Inke, and is therefore held fit to colour the haire or any other thing.

6. Hedera quinquefolia Virginenſis. Virginean Ivie.

I have deſcribed this in my former booke under the title of *Vitis ſeu potius Hedera Virginenſis*, ſo exactly that it were needleſſe labour to doe it here againe, I muſt therefore referre you thereunto for it; I onely ſhew you the figure of a branch thereof with the other.

7. Hederaceis foliis planta Lobelij. Lobels Ivie leafed plant.

Not finding a fitter place then this, let me with *Bauhinus* ſet it with the Ivies for the leaves ſake, although *Lobel* calleth it *Cyclaminos hederaceis foliis*. This plant (ſaith he) hath ſtalkes about a cubit long or better which are ſoft and ſlender, having Ivie like leaves upon them: the flowers are long and hoodded, of a pale purple colour. This hee found on the hills in paſſing through *Italy*.

The Place.

The firſt is well knowne to every child almoſt, to grow in woods upon the trees, and upon the ſtone walls of Churches, houſes, &c. or ſometimes to grow alone of it ſelfe, as is before ſayd, yet very ſeldome: the ſecond is ſayd to grow in *France* and ſome places of *Turkey*, and ſome ſay in *Naples* alſo: the third *Pona* and *Lobel* ſay grow in *Campania* and *Apulia*, and yet ſowen in gardens of *Italy* and alſo of *Germany*: the fourth groweth in moyſt and ſhadowie places for the moſt part, under hedges and the corner of waſte grounds, lanes and the like, the two next grow in the Northweſt parts of *America*, where our *Engliſh Colonies* are planted, the laſt as is before recited.

The Time.

Our Ivie flowreth not untill *July*, and the berries are not ripe uſually untill about *Chriſtmas*, that they have felt the winter froſts: of the other two wee can ſay no more, then that wee have little acquaintance with them, yet *Geſner in hortis* ſaith, that he ſaw that with yellow berries in *Germany*, the *American* ſorts are very late with us.

The Names.

It is called in Greeke κισσὸς and κιττὸς *Ciſſus* and *Cittus*, *quem a Ciſſo dictum fabulantur Græci, puſione Citti ſive Liberi patris ſultantis in Hederam ab illo verſo; Athenienſes enim Cittum Bacchum ipſum vocant, adeoque cum illo coronobatur, quia ut ille ſemper juvenis ita hæc perpetuo viret*: but *Pena* and *Lobel* ſay they thinke it is rather deduced from κὶς, *id eſt, Curculio, qui triticum hordeumque terebrat, etenim importuna amaſia radicatis propagationibus, arbores amplexu enecat, & exedit ut vermis triticum*, or from κισσηρὶς *pumex ſive poroſus lapis, quia ut ille aquam, ita hoc lignum textura poroſa, & ſpiraculis innumeris pervia vinum tranſmittit, unde Catoni & Varroni Ciſſimbion poculum hederaceum eſt*, and *Coſtæus* from theſe it is likely ſaith, that a cup made of Ivie wood will not hold any wine therein, in Latine *Hedera*. *Hederam vero Pompeius dictum cenſat quod hæreat, vel potius edita petat, vel quia id cui adhæſerit edit & enecat*: the *Arabians* call it *Cuſſus*, the *Italians Hedera*, the *Spaniards Edera*, the *French Lierre*, the *Germans Eghen*, the *Dutch Veyl*, and we in Engliſh Ivie: The firſt is called of all writers either *Hedera* ſimply, or *Hedera arborea*, (eſpecially that which groweth alone by it ſelfe, which therefore the ancients called *Orthociſſos*) *Hedera recta*, of ſome *Corimboſa*, (and of *Pliny Hedera rigens* and *ſcandens* by ſome to diſtinguiſh it from the other ſort of Ivies) or *nigra*, to ſhew the difference from the ſecond called *alba*, white or gray: ſuch ſaith *Lobel* in his *Adverſaria* were ſhewed me at *Piſa*, which *Theophraſtus* ſpeaking of the diverſities in his time obſerved, and *Pliny* from him ſay differ, ſome having white leaves as well as berries, which made *Virgil* to ſay *Candidior cygnis hedera formoſior alba*, then Swarne more lovely, or then the white Ivie, ſome alſo having rounder and thicker bunches of Berries which he called *Corymbi*, or *Hedera Corymbia*, and ſome having greater berries and thinner branches called *Salenitium*: the third is called as *Pliny* ſaith *Niſia* and *Bachica*, of the *Athenians Acharnica*, and of the *Grecians Chryſocarpos*, which *Dioſcorides* and *Dalechampius* as *Lugdunenſis* ſaith call *Dionyſias*, wherewith the Poets were wont to be crowned, and yet the blacke berried Ivie, whereof it is a *ſpecies*, is in ſome Authors called *Dionyſia* alſo: the fourth is called *Hedera Helix*, and *ſterilis* by all our moderne writers, and *Lobel Provoluta Hedera Helix*, and taken to be the *Helix* of *Dioſcorides*, *Theophraſtus*, *Pliny* and the reſt, which they make thē third *ſpecies* of their climing kinds, but we have not ſeene it to climbe up in that manner, as the other doth in our countrey, lying as I ſayd for the moſt part on the ground, although ſometimes it riſeth up (and therefore *Pena* & *Lobel* in *Adverſaria* ſay that it ſhould more properly be called *Hedera terreſtris* then the former taken to be *Chamæciſſus* of *Dioſcorides*: (but it is but his bare opinion without good adviſe) yet *Iohannes Thalius* in *Harcynia ſylva*, ſaith that he there found it climing as well upon trees, as creeping upon old walls & ſtones: Of this ſort *Theophraſtus* and *Pliny* record divers ſorts, ſome whoſe leaves were white, ſome greene, & others of divers colours, which is called *Thracia*: ſome alſo to differ in the length of the ſmaller branches, (ſaith *Theophraſtus*) in length of the ſpaces, betweene the joynts ſaith *Pliny*;) and in each of theſe againe are certaine differences, as in the greene ſort, ſome had longer, ſome thicker & ſome thinner leaves, and in others ſmaller, and in the white ſort, ſome that had greater & others leſſer leaves; and in the party coloured ſort, ſome whoſe leaves were thicker or thinner, or more or leſſe parted, yet in this it chiefly differeth not ſay they, that it is barren in all, not bringing any fruit, which yet ſome ſaid was rather for want of age, in that in time it did beare, and turne into the other ſort, thus ſay *Theophraſtus* and *Pliny*, with many more things too long to inſert here: they that are diſpoſed to reade the Authors themſelves may be informed of the particulars. *Bauhinus* maketh the *Hederula* of *Tragus* to be a differing ſort from others, calling it *Hedera humi repens*, which yet *Tragus* himſelfe diſtinguiſheth not, ſaying that that Ivie, which while it is young bringeth no fruite, when it is growne older doth, and there is no difference in his two ſorts of *Hedera* and *Hederula* but in the age: the two *American* ſorts are ſo termed by us as they are in their titles.

The Vertues.

Galen ſheweth that Ivie is of divers qualities, ſome ſharpe and hot, others hot, and ſome moiſt, others cold, dry and aſtringent; being therefore ſuch an inconſtant *Hermes*, it is the more carefully to bee applyed and eſpecially in cauſing barrenneſſe in man or woman, if they ſhall take too often thereof, and procureth a weakeneſſe and

and trouble in the braines, and senses: A Pugill of the flowers (that is as much as one may take up with their three fingers together) which may be about a dramme, saith *Dioscorides*, drunke twice a day in red wine, helpeth the Laske and blooddy flix. It is an enemy to the nerves and sinewes being taken much inwardly, but is very helpefull unto them being applied outwardly: *Pliny* saith that the yellow berries are good against the Iaundies, and taken before one be set to drinke hard will keepe him from drunkennesse, and helpeth those that spit blood, and that the white berries being taken inwardly killeth the wormes of the belly, or applyed outwardly: the juice of the roote is good to be taken against the biting of the *Phalangium*, or deadly Spider: the berries are held by many Empericks Quacksalvers and Chirurgions to be a singular remedy both to prevent the Plague or pestilence, before it be taken, as also to free them from it, that have got it; by drinking the berries made in powder for two or three dayes together: they being taken in wine do for certaine helpe to breake the stone, provoke urine and womens courses as *Tragus* saith, yea so powerfull they are in those parts, that a bath made of the leaves and berries for women to sit in, or over the fumes, or a pessarie made of them and put up doth mightily prevaile to bring them downe, and to draw forth the dead birth and secondines or afterbirth, but this is to be cautelously used, and not but upon necessitie, or extremitie: the leaves of Ivie while they are fresh, boyled in Vinegar, and applyed warme to the sides of those that are spleneticke, or troubled with the Spleene, ache or stitch in the sides doth give them much ease: the same also applyed with some Rosewater and oyle of Roses to the forehead and temples, doth ease the headach although it be of long continuance: the fresh leaves boyled in wine, and old filthy sores and Vlcers that are hard to bee cured washed therewith, doth wonderfully helpe to clense and heale them, as also effectuall for greene wounds to heale them quickly and soder up the lippes thereof: the same also is effectuall to heale scaldings of water, and burnings by fire, and the exulcerations that happen thereby, or upon the sharpenesse of salt flegme, and hot humours in other parts of the body: the juice of the leaves or berries being snuffed up into the nose purgeth the head and braine of thinne rheume, which maketh defluxions into the eyes and nose, and cureth the Vlcers and stench therein: the same dropped into the eares, doth helpe the old and running sores of them: five of the yellow berries bruised and heated with oyle of Roses in a Pomgranet rinde and dropped into the eare of such as have the toothache, on the contrary side of the paine easeth them thereof: the berries or the leaves used causeth the haire to grow blacke. The fresh leaves are commonly used to bee layd upon issues whersoever, in the armes legges, &c. to keepe them open, and to draw forth the humours that fall thither: the Gum of the Ivie, which in the hot countries is gathered from the body and branches, is exceeding sharpe and hot, burning and exulcerating the skinne, yet it is used being dissolved to take away superfluous haire in any place, and to destroy Nits and Lice whersoever: the same dissolved in Vinegar and put into hollow aking teeth doth ease the same, and being often used will cause them to fall out: Some doe use it as a baite with other things to kill fish: the wood made into a cup, and those that are troubled with the Spleene shall finde ease, and be much holpen thereof, if they continually drinke out of it, so as the drinke may stand some small time therein before it be drunke. *Cato* writeth an experiment how to finde out the deceit of Vintners and others that put water to their wine, which is this, that if you suspect your wine, you shall put some thereof into such a cup that is made of Ivie wood, and that if there be any water therein it will remaine in the cup, and the wine will soke through; for the nature of Ivie wood saith he and *Varro*, is not to hold any wine, so great an antipathy there is betweene them: the fume of Ivie branches being burned driveth away Gnattes and Battes, and all other hurtfull and noysome creatures.

CHAP. XCV.

Cymbalaria Italica Hederacea. The *Italian Gondelo* or Ivie like leafe.

THis small herbe creepeth on the ground with slender threddy branches all about, taking hold on walls or any thing it meeteth, by small fibrous rootes, which it shooteth out at the joynts as it runneth: at the severall joynts grow small broad, and almost round leaves, cut in on the edges into corners, somewhat like unto a cornered Ivie leafe, each standing upon a very small and threddy stalke: at the joynts likewise stand severall small flowers upon slender footestalkes, fashioned like unto a Snapdragon or Fluellen flower, with a taile or spurre behind it, mixed of yellow whitish and purple colours; and the spurre as it were washed over with a purplish also; in whose places after they are fallen come small round heads, conteining small blackish seede.

The Place.

It groweth naturally in divers places of our Land, although formerly it hath not beene knowne to bee but in Gardens, as about *Hatfield* in *Hartfordshire*, both in their Gardens and other places that are shadie upon the ground, for there it will alwayes best like to grow, as also upon the thatched houses in the Norrh parts, as I am given to understand, and most abundantly in *Lancashire*, and in my Garden where it runneth up from the ground on the wall a pretty height.

The Time.

It flowreth seldome untill the end of *July*, and in *August*, but continueth with mee in flower untill the great frosts destroy it, and the seede is ripe soone after the flowers doe shed.

The Names.

This never as I thinke met with a Greeke Author to give it a name, although the name *Cymbalaria* by the Latines is derived from the Greeke word κύμβα *Cymba*, a boat; or from the herbe κύμβαλιον *Cymbalion*, which *Dioscorides* saith was a name given to his *Cotyledon*, or *Umbilicus Veneris alter*, whereof divers would make this to be eyther it or a *species* of it, and thereupon gave it the name of *Cymbalaria*, or *Cymbalaris*: the Apothecaries of *Venice*, *Padoa*, and divers other places in *Italy*, where it familiarly groweth upon their mudde walles, &c. take it (either by ignorance not knowing the right, or by penury not having the right) for *Cotyledon* or *Umbilicus Veneris*, and so use it instead thereof in *Unguento Populeon*, as *Matthiolus* saith, and therefore *Lonicerus* calleth it

Umbilicus

Umbilicus Veneris officinarum. *Lobel* calleth it *Cymbalaria Italica hederaceo folio*, and *Columna Linaria hederæ folio*: for he in this as in all other herbes saith, the flowers and seede doe most truly demonstrate the *species* of every *genus*, which I hold to be the best *judicium* an Herbarist can use, and therefore I would make it a *species* of the *Elatine* that is *veronica fœmina*, rather then *Linaria*, every part herein, and not one as in *Linaria* being answerable thereunto: wee may call it in *English* eyther Iviewort or the Ivie like leafe as it is in the title, or from *Cymbalion*, the *Italian Gondelo*, untill a more fit name may bee given it.

Cymbalaria Hederacea. The Ivie like leafe.

The Vertues.

It is held to be cold and moist (and therefore the *Italians* thought it a fit substitute for *Umbilicus Veneris* (which I hold is farre better then that kind of *Ranunculus*, called *Cotyledon aquatica*, which our Apothecaries use in stead thereof, because it is hot sharpe and exulcerating, which are quite contrary to the qualities of that herbe they use it for, although the forme of the leafe being round, caused the name of *Cotyledon* to bee given it) yet hath it some astriction also, whereby as *Matthiolus* saith it is very profitable for women that have the whites, to stay them, being eaten often in Sallats, as the manner of the *Italians* and other Nations is, more then of ours, and therefore a Conserve made of the leaves, or Syrupe made of the juice, we may use in stead of their Sallats: It is held as *Matthiolus* saith with divers, to have some properties that the true *Umbilicus Veneris* hath, which you shall finde related in the due place: this is with many held, and some found by good experience to cure wounds, and to stay the bleeding of them, the juice thereof being dropped into them, or tents dipped therein and put into them: thē herbē bruised and applyed outwardly ripeneth Impostumes: The distilled water of the herbe serveth well for all the uses aforesayd.

CHAP. XCVI.

Leontopetalon. Lyon leafed Turnep or blackē Turnep.

THe rootē of this herbe is tuberous, somēwhat like a Turnep or Sowbread, or great Earth Chesnut roote, being of a blackish gray colour, with divers small bunches or knobbes on the sides, from whence spring up divers large and long leaves, much divided or cut into divers parts (*Dioscorides* saith like unto Coleworts or Poppies, *Pena* and *Lobel* say more like unto Peony leaves, but wee finde that they are more jagged or cut in) of a darke yellowish greene colour (with us, but it may be of a darker yellow colour in the naturall places, neare unto the colour of a Lyons haire, and thereof rose the name of Lyon leafe, as I take it:) from whence riseth up a straked stalke, spotted with pale purplish lines and strakes, divided into many branches, set at the joynts with smaller leaves and lesser cut in; on the toppes whereof stand divers small flowers, made of five leaves a peece, of a darke or browniish yellow colour (red like an Anemone, and therefore called of some ἀνεμόνε saith *Dioscorides*, and those that follow his Text onely) on the outside, and yellow on the inside: after which come small poddes, thicker and shorter then those of *Radix Cava*, or *Fumaria bulbosa*, Hollow roote, else somewhat like as the whole plant doth in some sort resemble it, with small round seede therein.

Leontopetalon. Lyon leafed blacke Turnip.

The Place.

It groweth in the fields about *Aleppo* in *Syria*, in *Græcia* also, *Candy* and *Naples*: the roote and seede have beene sent sometimes to us, but we could seldome have it to live above a Summer, or the greater roote once to winter with us.

The Time.

It flowreth in the Winter time in *Candy* as *Bellonius* saith; but very late if at all with us.

The Names.

The Greekēs call it λεοντοπέταλον, and thē Latinēs *Leontopetalon* also;

alſo, for the cauſe ſhewed in the deſcription as I thinke: divers other Greeke names it hath needeleſſe to be remembred here, and Latine alſo, as *Rapeium*, *Papaverculum*, *Semen Leoninum*, *Brumaria*, and *Pes Leoninus*, and *Pata leonis*; but yet there is another *Pata leonis* called *Alchymilla*, as wee have ſhewed before. *Camerarius* from *Rauwolfius* ſaith, that they about *Aleppo* call it *Aſlab*. *Apuleius* calleth it *Leontopodium*, and ſo doth *Ætius* alſo, in aſcribing the ſame qualities to his *Leontopodium*, that *Dioſcorides* and *Galen* doe, unto the *Leontopetalon*: *Oribaſius* alſo ſaying that *Leontopetalon* was called *Leontopodium* in his time. We may call it in *Engliſh* either as it is in the title, or according to the forme, Blacke *Syrian* Codded, or *Syrian* blacke bulbed Fumiterry, for both *Anguilara* and *Cæſalpinus* doe make the *Radix Cava* or *Fumaria bulboſa*, to be *Leontopetalum alterum*, and *Leontopetali genus quibuſdam*, *haud planè ineptè*, to diſtinguiſh it from the next that is like it alſo.

The Vertues.

Galen ſaith it is hot and dry in the third degree, and that it hath a digeſting quality therein alſo; *Dioſcorides* ſaith that it is the moſt powerfull remedy ſpeedily to helpe thoſe that are bitten by any Serpent, if the roote bee taken in wine: the ſame alſo is very effectuall to helpe the Sciatica, not onely to be put into gliſters that are made for that purpoſe, but alſo to be applied outwardly, and by the digeſting faculty is effectuall to cleanſe and heale old and filthy Vlcers. *Rauwolfius* in his *Hoedoporico*, or *Iournall* of the Eaſt Countries, reporteth that the inhabitants about and in *Aleppo* doe uſe the powder of the old and greater roots of this herbe, to take out ſpots out of their garments by rubbing them therewith.

CHAP. XCVII.

Chryſogonum. Oaken leafed blacke Turnep.

THis Plant ſo like unto the laſt hath cauſed me to joyne it next unto it, whoſe deſcription according to the beſt authors that have ſeene it and ſet it forth, and mine owne obſervation of their figures, you ſhall have in this manner. It hath a tuberous roote like unto *Leontopetalon*, or the Earth Cheſnut, called *Balanocaſtanon*, or *Bulbocaſtanum*, of a browne colour on the outſide and very red within, ſending forth three or foure long winged leaves, lying on the ground, *Rauwolfius* ſaith he never obſerved ſo few as three, ſtanding upon a very ſmall and ſlender ſtalke or ribbe, and are made of many leaves, ſtanding oppoſite one unto another, at ſpaces or joynts, and ſome at the ends, every one whereof is ſmall at the bottome, and broad at the point, where it is cut into ſome diviſions, making them ſeeme like unto Oaken leaves, but much leſſer (*Rauwolfius* figure thereof ſeemeth to expreſſe but two leaves at a ſpace, *Alpinus* figure five or ſix yet ſmaller) of a very darke greene, from among which leaves riſeth up a ſtalke a cubit high, without any leafe upon it, divided at the toppe into many ſmall ſprigs or branches, bearing every one a yellow flower, made of five leaves a peece, larger then thoſe of the laſt: after which come ſmall ſhort pods, ſmall at the further end, with a little round knobbe, wherein lye the ſeede (like the other as I thinke.)

Chryſogonum. Oaken leafed blacke Turnip.

The Place.

It groweth in the fields among the corne in *Syria*, as *Rauwolfius* ſaith, who there found it.

The Time.

The time of the flowering is not expreſſed, but it is likely it being ſo like the former, ſhould flower about the ſame time.

The Names.

Dioſcorides onely of the ancient Greeke Authors maketh mention of it, and calleth it χρυσογονον *Chryſogonum*, which the Latines alſo follow, and if wee deſcant upon the name or Etimologie, it is a yellow knee or joynt, which it is likely although it be not expreſſed in the deſcription the ſtalkes have. *Rauwolfius* onely and *Pona* in his *Italian Baldus* of the late writers have ſet forth the figure of it, for *Durantes* hath nothing but the text of *Dioſcorides*; *Lugdunenſis* in his Appendix hath the Text of *Rauwolfius*: and *Bauhinus* hath it from them, and *Pona* who had it from *Padre Malocchio*, Preſident of the Garden at *Piſa*: I have in this as in the former given it an *Engliſh* name, according to the forme that in my minde it beareth, eyther of which may ſtand untill a more proper may be given it.

The Vertues.

This as the former is appropriated by *Dioſcorides* (for I cannot finde that *Galen* hath made mention of it) to heale the bitings of venemous beaſts, and eſpecially the Shrew or poyſonfull Mouſe: and thereby may bee conjectured to bee of the ſame facultie in the other things with the former.

CHAP.

CHAP. XCVIII.

Leontopodium. Lyons foote, or Mountaine Cottonweede.

BEcauſe the *Leontopetalon* was called *Leontopodium* alſo by divers, I thinke it fitteſt to bring it next to conſideration, and becauſe it is a kind of Cottenweede or Cudwort, I will in the next Chapter ſpeake of the other ſorts of Cudworts, Golden Tufts, and Mouſeare, as being neareſt in forme and vertues one unto another.

1. *Leontopodium majus.* The greater Lyons foote or Mountaine Cottenweede.

This greater (for ſo I call it in regard of the next which is ſmaller then it) Lyons foote or Mountaine Cottonweede, hath divers ſmall and ſomewhat narrow leaves lying upon the ground, hoary or woolly all over, yet more hairy white underneath then above: the ſtalkes riſe up about halfe a foote or more high, ſet with ſuch like leaves thereon unto the toppes, where ſtandeth one great browne head apeece, compaſſed about with many woolly or hoary white leaves, repreſenting the hairy foote of a Lyon, Hare or Dove, or ſuch like beaſt, whereof it tooke the name; out of which head come forth many ſhort threds, which make the flowers ſeeme to have holes therein, wherein lyeth afterwards ſmall browniſh ſeede, wrapped in ſo much downe, that it is hardly to bee found or ſeene: the roote is ſmall and long and ſomewhat wooddy, with divers ſtrings and fibres thereat.

2. *Leontopodium minus.* The leſſer Lyons foote.

The leſſer Lyons foote riſeth up with one ſmall ſtalke for the moſt part, with divers leaves thereon, ſomewhat longer, but not broader then the former, at the toppes whereof ſtand divers woolly leaves, and in the middle of them three or foure or more heads of flowers, like unto the other ſmall Cudworts conſiſting of thrums, of a pale yellow colour, with ſome blacke haires among them: the ſeede is like the other, and ſo is the roote alſo.

The Place.

The firſt is found on the Alpes of *Germany*, and *Baldus* of *Italy*: the ſecond on divers mountaines in *Germany* and *Italy* alſo.

The Time.

They flower in *July* and ſometimes in *Auguſt*.

The Names.

It is called in Greeke λεοντοπόδιον *Leontopodium*, and ſo in Latine alſo, which is as much as *Pes Leoninus* Lyons foote, for the cauſes declared in the deſcriptions, and κήμος *Cemos*, as it is among the other names were given it as *Dioſcorides* ſaith; yet ſome affirme that the title of *Leontopodium* is not fouud in ſome copies of *Dioſcorides*, but *Cemos* or *Camos*, ſo that *Cemos* and *Leontopodium* be one thing, and therefore *Pliny* in his 27. Booke and 8. Chap. ſpeaking of *Catanance*, which was onely uſed about love matters, ſaith, that for the ſame cauſe *Cemos*

1. *Leontopodium majus.*
The greater Lyons foote or mountaine Cottonweede.

2. *Leontopodium minus.*
The leſſer Lyons foote.

being

being ſo uſed he would ſay nothing of it. There is much controverſie alſo among writers about *Leontopodium* which ſhould be the right, ſome accounting one plant and ſome another, and ſome accounting none that are extant to be right: *Matthiolus* and *Lobel* ſet forth theirs, which is the firſt here expreſſed, which *Cluſius* refuſeth, accounting it but a kind of *Gnaphalium*, or Cudweede, calling it *Gnaphalium Alpinum* (as though *Leontopodium* were ſo much differing from *Gnaphalium*, that there were little or no likeneſſe betweene them:) *Lonicerus* hath his *Leontopodium*, which is the *Echium Scorpioides paluſtre* of *Bauhinus*, or *Myoſotis Scorpioides* of *Lobel*. *Apuleius*, *Ætius*, and *Oribaſius* ſay as I ſhewed before in the Chapter of *Leontopetalon*, that it was called *Leontopodium*. *Brunfelſius* maketh the *Alchymilla*, which the ſhops beyond Sea called *Pata Leonis*, to bee *Leontopodium*, which *Matthiolus* noteth as an errour in him. *Ioſephus de Caſabona* as *Cluſius* ſaith in his Hiſtory of Plants, ſent him ſome dryed plants received out of *Candy*, by the name of *Leontopodium*, which hee judgeth rather to belong to the kinds of ſmall Plantaines, yet *Cluſius* himſelfe ſetteth it forth under the name of *Leontopodium Creticum*; which plant alſo as he ſaith *Cortuſus* ſent him, for *Catanance*. *Honorius Bellus* as *Cluſius* ſaith there alſo ſent him ſome plants, and the figure alſo drawne of the ſame or the like herbe, which hee calleth *Leontopodium Creticum aliud*, which as the other he judgeth but a *ſpecies* of the Ribwort Plantaine, all which ſorts of *Cluſius* are here before expreſſed in the twelft Chap. of this *Claſſis*. *Bauhinus* ſetteth downe no herbe peculiar for the true *Leontopodium* of *Dioſcorides*, but together with *Lugduneuſis* thinketh that *Pliny* his *Leontopodium* doth much differ from that of *Dioſcorides*, and maketh the *Leontopodium* of *Matthiolus*, *Lobel* and others, to be but *ſpecies* of *Gnaphalium*: yet becauſe I cannot ſee but that the firſt may as properly belong unto *Leontopodium* of *Dioſcorides*, as unto *Gnaphalium*, I have as you ſee ſet it downe by it ſelfe, *ſuum cuique judicium eſto*: the ſecond is the *Leontopodium parvum* of *Lobel* and others, which *Dodonæus* calleth *Piloſella minor altera*, and is *Gerard* his *Gnaphalium Alpinum*.

The Vertues.

The taſte hereof being aſtringent and drying with ſome bitternſſe in it alſo, doth teſtifie it is very availeable for all fluxes of blood or humors, as alſo effectuall for all ſores, eyther greene wounds or old ulcers, and conducible for whatſoever cures, the other Cudweeds may performe: but becauſe I have no author that expreſſeth the properties, nor any experience of my owne or others, to what diſeaſe or greefe it is a remedy, I forbeare to play the Phyſition, and appoint the practiſe any further: *pauca ſapienti*.

CHAP. XCIX.

Gnaphalium. Cudweede or Cottonweede.

THere be divers ſorts of theſe Cudweedes or Cottonworts, ſome of much beauty (whereof I have given you the knowledge of in my former booke, as the *Gnaphalium Americanum*, Live long, or Life everlaſting. *Gnaphalium montanum flore albo & purpureo*, White and Purple Catsfoote; *Gnaphalium Roſeum*, the Cotton Roſe, which I joyned to other plants of like beauty, forme and quality, whereof I ſhall not neede to make further mention) others that are of more vertue then beauty I meane to entreate in this Chapter, onely the figures of ſome of them I ſhall here inſert.

1. *Gnaphalium Anglicum vulgare majus.*
Our greate Common Cudweede.

The common Cudweede that groweth every where almoſt in this Land, eſpecially in dry ſandy grounds, riſeth up but with one ſtalke ſometimes, and ſometimes two or three, thicke ſet on all ſides with ſmall long and narrow whitiſh or woolly leaves, from the middle of the ſtalke almoſt up to the toppe; with every leafe ſtandeth a ſmall flower, of a dun or browniſh yellow colour, or not ſo yellow as others; in which heads after the flowers are fallen, come ſmall ſeede wrapped up with the downe therein, and is carried away with the winde: the roote is ſmall and threddy.

2. *Gnaphalium majus Germanicum.*
The greater *Germane* Cudweede.

3. *Gnaphalium minus ſeu herba Impia.*
The leſſer Cudwort or herbe Impious.

4. *Filago minor.* The leſſer Cudweede.

6 *Gnaphalium ſupinum oblongo folio.* Small leaning Cudweede.

2. *Gnaphalium majus Germanicum.* The greater *Germane* Cudweede.

This is in all things like the former, but that it groweth larger in ſtalkes, leaves, flowers and roote: And there is another ſort alſo of the ſame ſiſe that beareth the flowers not all along the ſtalkes, as the former doe, but at the toppes onely, not differing elſe in any thing, except the leaves may ſeeme to be ſomewhat ſhorter and a little more white and hoary then they. *Alterum.*

3. *Gnaphalium minus ſeu herba Impia.* The leſſer Cudweede or herbe Impious.

The leſſer Cudweede groweth up with a ſhorter ſtalke, and ſet with ſhorter leaves alſo, but ſomewhat more white or hrory, and a little broader; at the toppes whereof ſtandeth a larger and more open flower then in the former, and of a paler yellow colour, from the ſides of this ſtalke ſpring forth divers ſhort branches, ſet with ſuch like but ſmaller leaves then thoſe that grow below, with ſuch a like yellow flower as the other, which branches with their flowers doe alwayes riſe higher then the middle ſtalke, and the flower upon it: ſometimes alſo the branches will have other ſmall branches ſpring from them, bearing leaves on them, and flowers on the toppe of each, and theſe alſo riſing above the branches with their flowers in the ſaid manner, that the firſt branches did unto the maine ſtalke: the ſeede that followeth theſe flowers is carryed away with the winde as the reſt are.

4. *Filago minor.* The leſſer Cudweede.

This ſmall Cudweede ſhooteth forth a ſmall hoary ſtalke, full of branches from the very ground almoſt, with divers ſmaller, ſhorter and narrower leaves thereon, of a more duskie hoary colour then the former ſorts, ſome ſtanding ſingly, and ſome more at a ſpace, or joynt, the flowers hereof ſtand at the toppes of the ſtalkes and branches onely, and not all along as ſome of the former ſorts, or one branch above another as in the laſt, but all of them riſing almoſt to an even height, and are of an overworne yellow colour: the ſeede and roote are like the other.

5. *Gnaphalium minus latioribus folijs.* The leſſer broad leafed Cudweede.

Somewhat like unto the laſt is this ſmall Cudweede, whoſe ſtalke brancheth forth upwards, with ſome leaves thereon toward the bottome without order, and on the joynts of the branches two or three, which are all ſomewhat broad, ſoft and hoary, compaſſing the ſtalke at the bottome, and at the joynts with them ſtand divers ſmall hoary yellow heads of flowers, ſome in tufts upon a ſhort ſtalke, and ſome cloſe to the joynt, and ſome at the toppes of the branches wherein is contained ſmall ſeede, which falling away, ſpringeth up againe every yeare, for the roote periſheth after ſeede time.

6. *Gnaphalium ſupinum oblongo folio.* Small leaning Cudweede.

This ſmall leaning Cudweede ſpringeth forth with divers round hoary ſtalkes, not much above an handbreadth high, ſome whereof ſtand upright, and others leane downe to the ground, as though they would roote therein as they lye; whereon grow divers hoary, ſoft, and long leaves one above another without order, compaſſing the ſtalkes at the bottome, and ſmall pointed at the ends: the toppes of the ſtalkes are ſtored with many ſmall hoary heads, ſtanding in tufts together, with a yellow thrumme in the middle.

7. *Gnaphalium*

7. *Gnaphalium minimum repens.* Small creeping Cudweede.

This little Cudweede (which is sometimes found not above two or thee inches high) hath a small hoary stalke full of branches, about halfe a foote high or lesse, whereon grow smaller leaves then in any of the former, even almost as small as Southernwood leaves, but hoary as the rest are: the flowers are small and yellow in small hoary heads.

8. *Gnaphalium marinum sive Cotonaria.* Sea Cudweede or Cottonweede.

The Sea Cottonwort riseth up with divers small and very hoary white stalkes, about halfe a foote high, set with divers somewhat thicke, and somewhat long leaves, but very soft and hoary, or woolly all over, as though they were nothing but Cotton, bearing at their toppes some small hoary heads, with a yellow thrum breaking out of them, whose seede within is somewhat longer then the other: the roote is somewhat long and wooddy, but perisheth not yearely as divers of the other sorts doe.

The Place.

The first, the third, and fourth doe grow in barren dry sandy and gravelly grounds, in most places generally of the Land: the rest are found in the like places beyond the Seas, onely the last is found upon the west Sea coasts of our Land in divers places, as well as in others, although smaller, which maketh it seeme another sort.

The Time.

They doe all flower about *Iuly*, some earlier and some later, and their seede is ripe in *August*.

The Names.

It is called in Greeke γναφάλιον *Gnaphalium*, and so likewise in Latine *quod illi ad γναφάλιον pro tomento utuntur*, and γνάφειν *illis est vellere carpereve lanas*. It hath also divers other Latine names, as *Centunculus* and *Centuncularis*, *Tomentaria*, *Tomentum* and *Tomentitia*, *Cottonaria sive Bombax humilis*, especially the Sea kind, *Filago* and *Herba impia*, Herbe Impious, especially the third sort here set forth, for that as *Pliny* saith, the branches and flowers thereon rise above the middle stalke, or else as he saith, because no beast or other creature tasteth thereof: he also saith that it was also called *Chamæzelon* (as the copies have it) or rather *Chamexylon*, the low Bombast or Cotton plant, and *Albinum* from the whiteneſſe. The first is called by *Matthiolus Leontopodium alterum vulgare*, and *Pseudoleontopodium*. By *Lobel Gnaphalium Anglicum vel Belgicum folio longiore*: by *Tragus Heliochrysos sylvestris*, by *Lugdunensis Chrysocome lanuginosa*, and *Impiæ species*, by *Iohannes Thalius Gnaphalium vulgare majus*, by *Dodonæus Filaginis species altera*: the second is called by *Lobel*, *Filago*, and *Chrysocome Germanica*, and by *Durantes Chrysocome* and *Chrysitis*: It receiveth also with the *Germans* the same names that the former doth: the third is generally called with us *Herba Impia* and *Filago*, *a foliorum inusitata superbia*, and is the *Gnaphalium* of *Fuschius*, and *Matthiolus* (although he disprove him for so calling it) *Lobel*, *Lugdunensis* and others; of *Anguillara Cartasilago*. The fourth is the *Gnaphalium vulgare* with us, which *Dodonæus* and *Lobel* call *Filago minor*, and *Tabermontanus Gnaphalium medium*; the great *Germane* kind, which is the second here described, is a *species* hereof, but growing somewhat larger with them: the fift is the third *Gnaphalium* of *Clusius*, or the second of *Plateau*, which *Bauhinus* calleth *Gnaphalium minus latioribus foliis*: the sixt is *Clusius* his second *Gnaphalium*, or first of *Plateau*, called by *Bauhinus Gnaphalium majus lato oblongo folio*: the seventh is called by *Lobel Gnaphalium minimum*, by *Tabermontanus Gnaphalium minus*, and by *Bauhinus Gnaphalium minus repens*: the last is generally called *Gnaphalium marinum*, and *maritimum*, and *Legitimum* of *Clusius*: by *Lugdunensis Gnaphalium marinum tomentosum*, because hee hath another *Gnaphalium maritimum Dalechampij*, which *Bauhinus* taketh to be the *Stœchas citrina altera inodora* of *Lobel*, and he himselfe calleth it *Elichrysum sylvestre flore oblongo*, as I shewed you before among the *Stœchades*: the *Italians* call the *Gnaphalium*, *Gnaphalio*, *Filago*, and *Curtasilago*: the *French Petit cotton*: the *Germanes Rhurkraut*, and *Hijnschkraut*, the *Dutch Rurkruit* and *Roomelischencruijt*.

The Vertues.

These Plants are all astringent, or binding and drying, and therefore are profitable for desluxions of rheume, from the head into any other part, and to stay fluxes of blood whersoever, eyther at the nose or mouth, or by seige, which is the blooddy flix, and easeth the torments that come thereby, the decoction being made into red wine and drunke, or the powder taken therein: it stayeth also the immoderate courses of women, and is also good for inward or outward wounds, hurts and bruises, as the Westerne country people doe daily finde by experience, and helpeth children both of burstings and the wormes, and the disease called *Tenasmus*, which is an often provocation to the stoole and doing nothing, to be either drunke or injected or otherwise: the greene leaves bruised, and layd or bound to any greene wound, stayeth the bleeding and healeth it up quickly: the decoction or juice thereof doth the same, and doth helpe all old and filthy Vlcers quickly: most of them also serve for a weeke in Lampes, &c. to burne, but especially that which groweth by the Sea side. *Pliny* saith that the juice of the herbe Impious taken in wine and milke, is a soveraigne remedy against the Mumpes and Squinsie, and further saith, that it is mervailous what is reported of it, that whosoever shall take it shall never bee troubled with that disease againe, and therefore they give it their swine for the same purpose, and that which soever of them will not take it, will assuredly die thereof.

CHAP. C.

Chrysocome. Golden Tufts.

BEcause in the last Chapter there was mention made of *Stœchas Citrina* and *Helichrysum* called *Chrysocome* by me in the first *Classis* of this worke and 23. Chapter where I related the doubt what herbe should be the true *Chrysocome* of *Dioscorides*, and the controversie betweene *Lobel* and *Molinæus* thereabouts; I intend in this Chapter to shew you the true *Chrysocome* of *Dioscorides*, in my judgement and some other famous Herbarists, or at the least the truest yet published by any before them and me.

Chrysocome verior sive Coma aurea Germanica & Neapolitana.

The truer Goldilockes of *Dioscorides*.

This plant which in my judgement seemeth to be the neerest unto the *Chrysocome* of *Dioscorides*, shooteth forth

Chrysocome verior sive Coma aurea Germanica & Neapolitana.
The truer Goldilockes of *Dioscorides.*

8. *Chrysocome sive Stœchas Citrina Cretica.*
Candy golden Tufts.

9. *Chrysocome peregrina secunda Clusii sive Cretica altera.*
Spanish or *Candy* wilde golden Cassidony or Tufts.

12. *Stœchas Citrina sylvestror.*
Wilde yellow Cassidony.

ſundry hard, round ſtalkes halfe a yard high, ſomewhat thicke ſet unorderly with narrow, long greene leaves up to the toppes, where they branch forth into divers ſmall ſprigs, with ſmaller and ſhorter, leaves thereon then below, and bearing round heads of flower s compoſed of gold yellow thredds riſing from the middle of a few greene leaves which are as a huske to each of them, and abiding a long time in flower, and in their beauty, but *Columna* ſaith not a moneth till in the end they turne into downe, which with the ſmall yellow ſeede, grayiſh ſaith *Columna*, flyeth away in the winde; the roote is hard and wooddy at the head ſhooting therehence many, blackiſh fibres into the ground: the ſtalkes die downe yearely, and new ones riſe againe in the Spring.

The figures of theſe three following were overſlipped to be inſerted in their due place, which is the 23. Chap. of the firſt Claſſis in this booke, and therefore I thought it fitter to give you them here, and referre each of them by their number where into they doe belong then quite to neglect them and leave them out.

8. *Chryſocome ſive Stœchas Citrina Cretica.* *Candy* golden *Caſſidony* or Goldilocks.

The figure of this pertaineth to the eighth deſcription and number in the ſaid 23. Chapter of *Stœchas Citrina* in the firſt Tribe of this Booke.

9. *Chryſocome peregrina ſecunda Cluſii, ſive Cretica altera.* *Spaniſh* or *Candy* Caſſidony or Tufts.

The figure of this belongeth to the ninth nnmber in the ſaid Chapter, for the ninth there is miſſet for the tenth and eleventh.

12. *Stœchas Citrina ſylveſtrior.* Wilde yellow Caſſidonie.

Let this be referred alſo to the ſame place, and to be the twelfth in Number.

The Place and Time.

This firſt groweth in divers places of *Germany*, in the moiſt ſandy borders of unmanured fields as *Tragus* ſaith, in *Narbone* alſo as *Lobel* ſaith, and in *Naples* as *Columna* ſaith, and flowreth in *Iuly* and *Auguſt* or later.

The Names.

Tragus maketh it his third kind of *Linaria* and ſuppoſeth it to be the *Heliocryſos* of *Dioſcorides*, calling it in his owne Language *Groſſ Rheinblumen, id eſt, Amaranthus luteus major*, and is called by many other writers ſince *Linaria aurea Tragi*, by *Camerarius Linaria Auſtriaca*, by *Cluſius Oſyris Auſtriaca:* by *Lobel Linoſyris nuperorum*, but *Guilandinus* and *Columna* take it to be *Chryſocome* of *Dioſcorides* and *Pliny*, as you ſee I do here, for comparing all the parts, I cannot finde any other authors plant to come ſo neare to the right as this, & two ſo famous & worthy judicious Herbariſts being my guides, make me the more confident in my opinion. Let who will compare *Dioſcorides* his Text and the delineaments thereof, with *Columna* his *Animadverſaria* and amend it if he can: *Guilandinus* alſo tooke it to be the Hyſope of *Dioſcorides*, and therefore called it *Hyſſopus umbellifera*, but erroniouſly, for he ſaith the leafe of *Origanum* is like unto Hyſſope, but *Origanum* leaves are ſmall and round like Marjerome, and not long and narrow as this.

The Vertues.

This ſaith *Lobel* is ſharpe in taſte, gluttinous or clammy, and ſomewhat bitter like unto *Sena* and neare unto *Thymelæa*. *Tragus* writeth thus of it: the herbe with the flowers boiled in wine and drunke expelleth loves enchantments and all other poiſons, and helpeth Crampes and Ruptures, as alſo to diſcuſſe congealed blood in the body: it procureth womens courſes and expelleth the afterbirth: two drams of the dryed flowers in pouder taken in wine faſting, ſtayeth the cold Catarrhes or Diſtillations from the head: a bathe made of the flowers to ſweate therewith, or to ſit over the warme fumes, giveth much eaſe to thoſe that are troubled with the ſtone in the Kidneis, with paines of the mother, or the Sciatica: it is alſo layd in Cheſts and Wardrobes to preſerve Veſtments, &c. from Moaths.

CHAP. CI.

Piloſella ſive Auricula Muris. Mouſeare.

HAve alſo in my former booke given you the knowledge of ſome of the Mouſeares, as they may be moſt properly called, under the name of *Gnaphalium montanum album* and *purpureum*, white & purple Catsfoote, and *Gnaphalium Roſeum*, the Cotton Roſe, both which ſhall not againe bee deſcribed here, although I will ſhew you the figures of them.

1. *Piloſella minor vulgaris repens.* The common ſmall creeping Mouſeare.

The common Mouſeare that is more hairy then the other, is a low herbe creeping upon the ground by ſmall ſtrings like the Strawberry plant, whereby it ſhooteth forth ſmall rootes, whereat grow upon the ground many ſmall and ſomewhat ſhort leaves ſet in a round forme together, hollowiſh in the middle, where they are broadeſt, of a hoary colour all over as well above as below, and very hairy, which being broken doe give a white milke: from among theſe leaves ſpring up two or three ſmall hoary ſtalkes about a ſpanne high, with a few ſmaller leaves thereon: at the toppes whereof ſtandeth uſually but one flower, conſiſting of many pale yellow leaves, broad at the points, and a little dented in, ſet in three or foure rowes, the greater outermoſt, and the ſmaller inward, very like a Dandelion flower, and a little reddiſh underneath about the edges, eſpecially if it grow in a dry and not moiſt ground, which after they have ſtood long in flower, doe turne into downe, which with the ſeede is carried away with the winde.

2. *Piloſella Indica odorata* Sweete *Indian* Monſeare.

This Mouſeare hath a fleſhy roote creeping under ground, not growing deepe, with many fibres thereto, from whence ſhoote divers ſomewhat long leaves, ſet with very long haires: the hairy ſtalke that riſeth from them, groweth to be halfe a foote high, at the toppe whereof ſtand 7. or 8. faire flowers like the ordinary Mouſeare, but of a deeper yellow or Orenge colour, ſmelling very ſweete like Muske.

3. *Piloſella media vulgaris erecta.* Common upright Monſeare.

This other Mouſeare is very like the former, the difference betweene them conſiſteth in this, that the leaves are longer and greener on the upperſide, and ſomewhat hoary underneath, ſofter in handling, and not ſo much

1. *Pilosella minor vulgaris repens.*
The common small creeping Mouseare.

2. *Pilosella media vulgaris erecta.*
Common upright Mouseare.

4. *Pilosella altera erecta.*
Vpright Mouseare.

Gnaphalium montanum sive Pes Catt.
Mountaine Cudweede or Catsfoote.

Gnaphalium Roseum.
The Cotton Rose.

6. *Pilosella maxima Syriaca.*
Assyrian Mouseare.

7. *Myosotis Scorpioides hirsuta.*
Blew Mouseare.

8. *Myosotis Scorpioides repens.*
Small creeping blew Mouseare.

hairy, the ſtalkes of flowers ſtanding more upright and higher, this doth give milke if a leafe or ſtalke be broken as the former doth.

4. *Piloſella minima.* The ſmalleſt Mouſeare.

This alſo is in all things like the laſt, but that it creepeth not by ſtrings as the firſt doth, and is ſmaller by the halfe both in leafe and flower.

5. *Piloſella altera erecta.* Another upright Mouſeare.

This upright Mouſeare hath a few hoary and hairy broad and long leaves lying upon the ground, among which riſeth up a ſlender hairy ſtalke, bearing longer and narrower leaves thereon, and at the toppe two or three ſmall pale yellow flowers, like in faſhion unto the former, which turne into downe as they doe: the roote is ſmall tough and fibrous.

6. *Piloſella montana parvo flore.* Mountaine Mouſeare with many ſmall flowers upon a ſtalke.

The roote of this Mouſeare groweth not downewards, but lyeth under the upper cruſt of the ground, ſhooting forth divers long white fibres therein, whereby it is faſtned; it hath thoſe leaves that lye next to the roote ſhorter then thoſe that come up after, greene on the upperſide, but with very long white haires therein, making them ſeeme rough and underneath white, but leſſe hairy, from among which riſeth up a long round hollow greene ſtalke three foote high, ſmooth at the bottome and hairy at the toppe, having two or three ſuch leaves but leſſer thereon: at the toppes whereof ſtand many ſmall flowers, as it were in an umbell, but every one on a very long footeſtalke being yellow, and like in forme unto the former Mouſeares, as the ſeede is alſo which is carried away with the downe: this giveth milke likewiſe in the ſame manner that the others doe.

7. *Piloſella maxima Syriaca.* Aſſyrian Mouſeare.

I have ſo little acquaintance with this Mouſeare, that I can tell you no more of it, then *Lobel* hath ſet downe, whom I muſt follow line by line. And he ſaith it hath greater leaves then the former, many ſet together at the roote, being thicke and hoary white, feeling like Velvet; it ſendeth forth three or foure ſquare joynted ſtalkes, about a foote high, the flowers were not ſeene; the roote is hard and wooddy with fibres thereat.

8. *Myoſotis Scorpioides hirſuta.* Blew Mouſeare with a turning toppe.

Let me joyne unto theſe Mouſeares three other ſmall wilde plants, becauſe they are generally called Mouſeares, although as you ſhall heare by and by, divers authors have diverſly entitled them. This riſeth up with one ſtalk moſt uſually, and ſeldome with any more, which is round hairy, and about halfe a yard high, or better, at the bottome whereof grow ſomewhat long and broad hairy leaves, very like both for roughneſſe, ſhape and colour unto the wilde Borrage leaves: the ſtalke is ſometimes alſo branched and ſometimes not, with divers ſuch like leaves but leſſer and leſſer thereon up to the toppes of flowers, which turneth or windeth it ſelfe inward, like unto a Scorpions taile, or the herbe *Heliotropium* the Sun turner: the flowers which conſiſt of five ſmall round leaves apeece are of a pale blew colour, very much reſembling the flowers of Bugloſſe or wilde Borrage, with a yellow ſpot or eye in the middle, and ſtand all on one ſide of the ſtalke and branches: after they are paſt there come in their places ſmall rough flat heads, wherein the ſeede is conteined: the roote is ſmall and threddy.

9. *Myoſotis Scorpioides repens.* Small creeping blew Mouſeare.

This other is very like the laſt Mouſeare, but that it is ſmaller, moſt uſually having leſſer leaves and flowers on the branches, which doe not ſtand ſo upright, but trayle or creepe on the ground: the flowers alſo ſtand not on one ſide, but on both and open by degrees: the turning top (which is like the other) doth grow up and dilate it ſelfe, and are of a blew colour, and ſome more purple, with a yellow eye in the middle.

10. *Myoſotis Scorpioides minor floſculis luteis.* Small Scorpion Mouſeare with yellow flowers.

The ſtalkes of this Mouſeare are very ſmall and hairy, not above an hand breadth high, with little long leaves thereon upon long footeſtalkes: the toppes with flowers doe twine themſelves like the two laſt, each of them conſiſting of five leaves a peece, and are of a gold yellow colour wholly. The numbers in the figures muſt be altered from the firſt according to theſe of the deſcriptions.

The Place.

The firſt and third grow promiſcuouſly on ditch bankes and ſometimes neare or in the ditches, if they be dry, and in ſandy grounds: the ſecond in *America*: the fourth upon dry barren heathes, eſpecially upon *Hampeſtead* heath in that plenty that one can hardly ſet a foot but upon the heads of it: the fift is more rare and but now and then to bee met with in our Land, but more eaſily in *Germany*: the ſixt *Fabius Columna* found upon the hills *Equicoli* in the kingdome of *Naples*: the ſeventh was brought out of *Syria* unto *Lobel* as hee ſaith: the eigth and ninth grow in dry and barren grounds in many places of this kingdome: the former of the two I found in the backe cloſe of Sr. *Iohn Tunſtall* his houſe a little beyond *Croydon*. The laſt *Bauhinus* ſaith groweth by *Mompelier* on the moiſt Vallies of *Hortus Dei*.

The Time.

They doe all flower about *Iune* and *Iuly*, and abide greene all the Winter.

The Names.

Μυοσώτις in Greeke is *Auricula muris* in Latine, from whence theſe herbes are generally called *Myoſotis*, eſpecially two of the laſt, which are thought to be ſomewhat anſwerable to *Dioſcorides* his *Myoſotis*, becauſe both of them have blew flowers: *Lobel* calleth them *Alſine Myoſotis*, *Auricula muris*, and *Myoſotis Scorpioides*, referring them to the kinds of Chickweeds. *Dodonæus* calleth the former of the *Scorpioides*, *Myoſotis Scorpioides*, and maketh it his third kind. *Bauhinus* confoundeth the two ſorts of *Myoſotis Scorpioides* together, taking the land kinds to bee thoſe of the water, whereof *Geſner* his *Scorpioides aquaticum*, and *Thalius* his *Echij paluſtris altera ſpecies* is one, but he is therein deceived, he calleth this *arvenſe* and the other *paluſtre*. *Cæſalpinus* doth call it *Heliotropium minus alterum*, becauſe the head twining with flowers is ſo like thereunto, and *Geſner Heliotropium erectum*. *Columna* calleth it *Echium minimum, vel Bugloſſum*, which cauſed *Bauhinus* to call them *Echium Scorpioides*, referring them rather unto that kindred, then unto any other. *Tragus* maketh the former of the three laſt his third *Auricula muris*, *Piloſella ſylv.* alſo, and *Euphraſia quarta* as he doth the other alſo, *Euphraſia cærulea*, becauſe as hee ſaith, ſome in his time would perſwade him they did belong to that family. The moderne writers call the former ſorts *Piloſella* from the hairineſſe of the leaves and ſtalkes, and *Auricula muris*, both from the forme and hairineſſe of them: ſome doe call the firſt & third *Piloſella major*, becauſe their *Piloſella minor* is the *Gnaphalium montanum*

num flore albo and *purpuraſcente*, ſome alſo call them *Piloſella minor*, in regard of the greater kinde that is called *Chondrilla aurea*, or *Auricula muris major* by *Tragus* and others, which is ſet forth in my former booke, and among the *Hieratia* in this. *Lacuna* called the firſt *Holoſtium*, *Cornutus* the ſecond as it is in the title, and ſaith that ſome did call *Hieratium Indicum*; and *Camerarius in horto* calleth the third *Lactucella ſylveſtris repens*: *Tabermontanus* mentioneth the fift and *Columna* the ſixt and laſt: the *Italians* call it *Peloſella* and *Peloſina*, the *French* *Piloſelle* and *Oreille de raouſouris Piluette* and *Velnette*, the *Germanes Nagelkraut* and *Meuſſor*, the *Dutch Naghelcruijt*, and *Muyſooren*, and we in *Engliſh* Mouſeare.

The Vertues.

The ordinary Mouſeare is hot and dry, although ſome write that it is cold, but the bitter taſte therein ſheweth it is hot and of a clenſing, binding and conſolidating quality: the juice hereof taken in wine, or the decoction thereof drunke doth helpe the Iaundies, although of long continuance, to drinke thereof morning and evening and abſtayning from other drinke two or three houres after; it is often uſed as a ſpeciall remedy againſt the ſtone and to eaſe the torments that ariſe thereof, as alſo other tortures or griping paines of the bowells, the decoction thereof with Succory and Centory, is held very effectuall to helpe the dropſie, and them that are enclining thereto, and the diſeaſes of the milt and ſpleene: it ſtayeth the fluxes of blood, eyther at the mouth or noſe, and inward bleedings alſo, for it is a ſingular wound herbe, for either inward or outward wounds: it helpeth the bloody flix, and ſtayeth the abundance of womens courſes: the juice or decoction of the herbe taken before the fit of a quartane Ague, is ſayd to keepe backe or much to leſſen the fit, and by the uſe of it to take it quite away. There is a Syrupe made of the juice and Sugar, by the Apothecaries of *Italy* and other places, which is of much account with them, to be given to thoſe that are troubled with the cough or tiſicke, which is a conſumption of the whole body, as well as of the lungs; the ſame alſo is ſingular good for ruptures or burſtings: the greene herbe bruiſed and preſently bound to any freſh cut or wound, doth quickly ſoder the lippes thereof, and the juice, decoction or powder of the dryed herbe is moſt ſingular to ſtay the malignitie of ſpreading or fretting Cankers or Vlcers whereſoever, as well thoſe in the mouth as ſecret parts of men or women: the diſtilled water of the plant is availeable in all the diſeaſes aforeſaid, and for wounds and ſores that are outward to waſh them therewith, and to apply tents or cloths wet therein. It is ſayd to be ſo powerfull to harden iron or ſteele, that if any edged or pointed toole ſhall be often quenched in the juice thereof, it will cut all other iron, ſteele or ſtone very eaſily, without turning edge or point. The old All-go-miſſe, I ſhould ſay Alchimiſts did much commend the juice of this herbe, that it would congeale and fix Mercury, but all theſe fancies are in theſe times quite diſperſed and driven away I thinke. Many skilfull Shepheards in the country doe avoyd as much as they can, to ſuffer their ſheepe long to feede in any ſuch paſtures and places where Mouſeare groweth in any plenty, leaſt they being bound therewith ſhould grow ſicke, and leane, and die quickly after. It is ſaid that if it be given any way to an horſe it will cauſe that he ſhall not be hurt by the Smith that ſhooeth him.

CHAP. CII.

Stratiotes Millefolium & Achillea Sideritis. Yarrow and Achilles Woundwort.

IF Might I confeſſe have fitly ſet theſe herbes next unto the *Sideritides* or Ironworts for their neare affinitie in name and nature, but accept them in this place ſeeing they are not placed there.

1. *Millefolium vulgare.* Common Yarrow or Millfoile.

The ordinary Yarrow hath many leaves ſpread upon the ground which are long, and finely cut into many ſmall parts that it excelleth the fine leaves of Tanſey, among which riſe two or three round greene ſtalkes with ſuch like winged leaves as grow below, but ſmaller and finer up to the toppes, where ſtand many ſmall white flowers in a Tuft or Vmbell cloſe together, each flower conſiſting of five ſmall round pointed leaves with a little yellowiſh thrumme in the middle, and ſmell ſomewhat ſtrong, yet not unpleaſant being rubbed in the hand: the roote is made of many long white ſtrings ſpreading deepe and far. There is ſome varietie obſerved in the flowers hereof, ſome being more white then others, as alſo thicker ſet together, and greater or ſmaller then others, one alſo with a round or tuberous roote, as bigge as an Haſle nut, wherein hath beene found a worme ſo ſmall that the ſight was ſcarſe able to diſcerne it.

2. *Millefolium majus album.* Great white Yarrow or Millfoile.

The great white Yarrow differeth not much in the forme of leaves or flowers from the former wilde Yarrow, but in the largeneſſe of the ſtalkes and leaves, the greene leaves being as large almoſt as thoſe of Tanſey, and in the flowers being greater ſtanding in a larger umbell, the ſmell whereof is a little more ſtrong then in the ordinary.

3. *Millefolium rubrum vulgare.* Common red flowred Yarrow.

This Yarrow differeth not in leaves from the firſt or common ſort, nor in the manner of growing but in the colour of the flowers, being of a deeper or paler red, or almoſt bluſh colour, yet with a yellow ſpot or thrumme in the middle.

4. *Millefolium flore rubro maximum.* Great red Millfoile.

This greater red Yarrow hath as large and great winged greene leaves as the great white Yarrow, but more finely cut in on the ſides: the ſtalkes are as great and high branching forth at the toppe, and ſtored with large umbells of flowers like unto them, but of a faire bright reddiſh colour, and in ſome paler, with pale yellow thrums in the middle which are of a fine ſmall ſent.

5. *Achillea Sideritis lutea.* *Achilles* yellow Woundwort.

This yellow Woundwort riſeth up ſomewhat high and creepeth not, the leaves whereof are long and very finely cut into many peeces, ſomewhat like unto Sothernwood but more ſappy and hoary alſo: the flowers ſtand in tufts like the other, but of a faire gold yellow colour: the ſeede is ſmall and long like unto Tanſey, and herein conſiſteth the difference betweene this and the two next yellow ſorts.

6. *Millefolium luteum ſive Achillea lutea.* Yellow Millfoile.

This yellow Millfoile or Yarrow hath hoary and ſhort ſtalkes ſcarſe a foote high ſometimes, creeping along by the

1. *Millefolium vulgare album vel rubrum.*
Common Yarrow or Millfoile, with white or red flowers.

5. *Achillea Sideritis lutea.*
Achilles yellow Woundwort.

6. *Millifolium luteum.*
Yellow Millfoile.

8. *Stratiotes millefolia cretica.*
White *Candy* Yarrow.

the ground and taking roote as it creepeth, the hoary leaves are long and much divided, but ſmaller and ſofter then the common white kinde: the flowers at the toppes of the ſtalkes are of a pale yellow colour, as well the outer leaves as inner thrum, ſtanding many together in tufts, and riſing out from hoary white huskes: the roote is ſmall and long with divers fibres thereat.

7. *Millefolium incanum Creticum.* Yellow *Candy* Millfoile.

The *Candy* Millfoile groweth with round hoary ſtalkes a foote high, whereon are ſet long, narrow, hoary, dented leaves ſomewhat like unto the leaves of Lavender cotton, the toppes of the ſtalkes branch forth into many cloſe tufts of pale yellow flowers of a fine ſmall ſent: the roote is ſtringy and creepeth as the laſt.

8. *Stratiotes millefolia Cretica.* White candy Yarrow.

This Millfoile riſeth up from a long white roote, with many long ſtalkes, a little bending downe, covered with an hoary downe, having divers winged leaves ſet at ſpaces, each whereof conſiſt of ſmall long leaves ſet thicke together on both ſides of the ribbes, which are hoary alſo, but not ſo much as the ſtalkes, at the toppes whereof ſtand ſmall umbells of white flowers ſomewhat like to thoſe of Tanſey.

9. *Achillea Sideritis ſive nobilis odorata.* *Achilles* ſweete Woundwort.

This woundwort (or Yarrow for thereunto it is moſt like) hath many large thinne cut leaves next the ground, more finely and deepely cut in unto the middle ribbe, and each part divided alſo, which maketh it to differ from the firſt, from whence riſe up more and taller ſtalkes with divers finer leaves ſet thereon, and at the toppes many flowers in tufts together, being both more in number and larger then the firſt or common ſort, of a whitiſh or reddiſh colour and yellow in the middle: the whole plant ſmelleth very ſweet: the roote periſheth every yeare after ſeedetime, and requireth a good ground and a rich to proſper in.

10. *Millefolium Alpinum incanum.* Small mountaine Milfoile.

This ſmall Millfoile hath many ſmall winged leaves, as finely cut in on the edges as the laſt, and ſomewhat hoary alſo, ſet on the ſtalkes that ſpread on the ground, and there take roote againe, among which riſe up ſhort ſtalkes not above a foote high, with ſome finer leaves on them to the toppe, where they beare many tufts of ſmall flowers thicke thruſt together, of a pale reddiſh or ſhining bluſh colour: the roote creepeth like the common ſort.

The Place.

The firſt with the varieties except that with a tuberous roote is very frequent in paſtures medowes &c. The third alſo but much more rare: the ſecond *Matthiolus* ſaith groweth in *Italy* and ſo doe many of the other: *Pena* ſaith the fift is found onely upon the high hills in *Narbone*, and *Cluſius* ſaith he found the laſt on the hills in *Stiria*.

The Time.

They doe all flower in the end of Summer and in *Auguſt*.

The Names.

Yarrow is called in Greeke στρατιώτης ὁ χιλιόφυλλος *Stratiotes Chiliophyllos*, that is *Stratiotes* or *Militaris millefolia*, and the eighth is called in Greeke Ἀχιλλεὺς σιδηῖτις *Achillea Sideritis*: *Stratiotes* or *Militaris* becauſe it was of much uſe in the Campes of Souldiers to heale their wounds, and *Pliny* ſaith in the third Chap. of his 25. Booke that *Achillea* tooke the name from *Achilles* the ſcholler or follower of *Chiron* who healed her with the wounds of *Telephus*: it is called *Millefolium* in Latine a *foliorum multitudine*, *Supercilium Veneris* alſo, *Acrum* and *Acrum ſylvaticum*. The *Arabians* call the *Achillea Egilos*, the *Italians Achillea* and the *Millefolium Millefoglio*, the *Spaniards Milhoyos yerva*, the *French Millefueille* and *L' herbe Militaire*, the *Germans Garb*, *Garben*, *Garwen* and *Schaffripp*, the *Dutch Gerwe*, and we in *Engliſh* Millfoile, Yarrow, and of ſome Noſebleede from making the noſe bleede if it be put into it, but aſſuredly it will ſtay the bleeding of it. Divers doe thinke that *Achillea* and *Millefolium* is but one herbe, becauſe divers authors have promiſcuouſly called them ſo. The firſt is called *Millefolium album* and *vulgare* by ſome, and *Stratiotes terreſtris*, *Stratiotes Millefolia*, *Achillea* and *Militaris* by others; the ſecond is mentioned by *Matthiolus*, *Lugdunenſis* and *Bauhinus*: the third is that of our Land and differeth from the fourth which is greater and redder, ſet forth by *Cluſius* under the name of *Millefolium rubro flore*, and by *Matthiolus* and others *Millefolium maximum*: the fift is called by *Pena Achillea montana Arthemiſſæ tenuifoliæ facie*, by *Matthiolus*, *Camerarius* and others, *Helichryſum*, and *Eliochryſum* by others, and in *Candy Lagochimithia*: the ſixt is called by *Cluſius Stratiotes millefolia flavo flore*, by *Geſner* and *Camerarius Millefolium floribus luteis*, by *Matthiolus Helichryſum Italicum*, and by *Bauhinus Millefolium tomentoſum luteum*, who thinketh it to be the *Tanacetum lanuginoſum* of *Lugdunenſis*, but as I ſayd in the Chapter of Tanſey he is therein much deceived as I thinke: the ſeventh is called by *Honorius Bellus* that ſent it from *Candy* to *Cluſius Stratiotes millefolia*, and ſaith it commeth neareſt to the deſcription of *Dioſcorides*, called by the *Candiots* μειοφυλλο *Miriophyllo*: the eighth is called by *Tragus Millefolium nobile* and *Stratiotes vera*, by *Geſner in hortis Stratiotes* and *Millefolium Stratiotes*, by *Tabermontanus Achillea ſive Millefolium nobile*, by *Matthiolus* and *Lacuna*, *Cordus* on *Dioſcorides* and in his hiſtory, of *Thalius* and *Durantes*, *Achillea*, by *Lugdunenſis* *Achillea Sideritis*, by *Dalechampius* upon *Pliny*: *Scopa regia Plinii*; but *Bauhinus* taketh it to be the *Tanacetum minus flore albo* of *Dodonæus*, calling it *Tanacetum minus album odore camphoræ*, and *Lobel* before him *Tanacetum minus candidis floribus*, but ſurely the ſeede that was ſent mee out of *Italy* by the name of *Achillea nobilis odorata*, and grew with me had no face or ſent of Tanſey, and evidetly differing from Yarrow alſo: The laſt is *Matthiolus* his *Millefolium minus* and *Cluſius* his *Millefolium Alpinum* and *Stratiotes millefolia minor*.

The Vertues.

As the face and forme of theſe two *Millefolium* and *Achillea* and all their varieties are very neare in reſemblance one unto another, ſo their vertues even by *Dioſcorides* and *Galen* are ſet downe to bee both alike, and no doubt but either of them that was next at hand, was applied for the ſame purpoſe that the other ſhould: for *Dioſcorides* ſaith that his *Achillea* ſodereth or cloſeth bleeding wounds and preſerveth them from inflammations, and ſtayeth the flux of blood in women being applied in a peſſary, as alſo if they ſit over the decoction thereof while it is warme, and is drunke againſt the bloody flux. Millfoile or Yarrow hee ſaith is of excellent uſe to heale both old and greene wounds, to ſtay bleedings and to heale Fiſtulaes: the powder of the dryed herbe taken with Comfrey or Plantaine water doth alſo ſtay inward bleedings, and put into the noſe as I ſaid before will doe the ſame: the juice thereof put into the eyes taketh away the blood and redneſſe therein, the oyle made thereof ſtayeth the

ſhedding

ſhedding of the haire : the decoction thereof made in wine and drunke is good for them that cannot reteine their meate in their ſtomack : it is accounted a good remedy for a quartaine Ague to drinke a draught of the decoction warme before the fit,and ſo for two or three fits together : the juice of the herbe and flowers taken either in Goates milke or in the diſtilled water of the herbe,ſtayeth the running of the reines in men and the whites in women,but it will be the more effectuall if a little powder of Corall Amber and Ivory be put thereto. *Matthiolus* doth wonderfully commend the powder of the dryed herbe and flowers againſt the piſſing of blood, ſo as to an ounce of the herbe a dram of fine Bolarmonacke bee put, and taken three dayes together faſting in a draught of milke : the roote or the greene leaves chewed in the mouth is ſaid to eaſe the paines in the teeth.

CHAP. CIII.

Polygonatum ſive Sigillum Salomonis. *Salamons* Seale.

THere are divers ſorts of *Salomons* Seale, ſome anciently knowne and ſet forth, others of later knowledge and invention, both from *Virginia* and *Braſſil*,as ſhall be ſpecified in this Chapter following.

1. *Polygonatum vulgare.* Common *Salomons* Seale.

The common *Salomons* Seale riſeth up with a round ſtalke, about halfe a yard high, bowing or bending downe the toppe, ſet with ſingle leaves one above another, which are ſomewhat large, and like unto the leaves of the Lilly Convally,or May Lilly, and of the ſame colour, that is, with an eye of blewiſhneſſe upon the greene,with ſome ribbes therein,and more yellowiſh underneath; at the foote of every leafe almoſt from the bottome up to the toppe of the ſtalke, come forth ſmall long white and hollow pendulous flowers, ſomewhat like the flower of the May Lilly, but ending in five longer points, for the moſt part two together, at the end of a long footeſtalke, and ſometimes but one, and ſometimes alſo two ſtalkes with flowers at the foote of a leafe, which are without any ſent at all, and ſtand all on theone ſide of the ſtalke;after they are paſt come in their places, ſmall round berries greene at the firſt, and blackiſh greene tending to blewneſſe when they are ripe : wherein lie ſmall white hard and ſtony ſeede : *Camerarius* in his Epitome citing *Matthiolus* as his Author ſaith that it is ſometimes found with red berries and with purple:the roote is of the thickneſſe of ones finger or thumbe, white and knobbed in ſome places with a flat round circle,repreſenting a Seale whereof it tooke the name,lying along under the upper face of the ground and not growing downeward but with many fibres underneath.

Racemis rubris et purpureis.

2. *Polygonatum majus.* Great *Salomons* Seale.

This other *Salomons* Seale is in all things like the former, but in the bigneſſe of the leaves and height of the ſtalkes, having larger flowers upon ſhorter footeſtalkes, and more ſtore ſet together at a leafe,and larger roots.

3. *Polygonatum majus flore majore.* The great flowred *Salomons* Seale.

This great flowred *Salomons* Seale hath ſhorter ſtalkes, not above a foote high, and ſtanding more upright and

1. 3. *Polygonatum majus vulgare & majus flore majore.*
The greater ordinary *Salomons* Seale,and that with greater flowers.

6. *Polygonatum latifolium ramoſum ſive quartum Cluſii.*
Broad leafed branched *Salomons* Seale.

ſomewhat

somewhat flatter then the former, the leaves are shorter and rounder then it, but stand thicke together, the flowers are larger then in any of the former, and sweeter, smelling like Hawthorne flowers, more also standing at each leafe: the berries that follow are large like the last, and so is the roote also, especially if it grow in good ground, or else smaller.

4. *Polygonatum maximo folio.* The greatest leafed *Salomons* Seale.

This *Salomons* Seale groweth in the same manner that the former sorts doe, with a stalke rather greater and higher then the last, but not so upright, the leaves hereof are larger by halfe then it, almost as great as the leaves of *Elleborus albus*, or the white Neesewort, of a paler greene colour, and not so whitish or yellow underneath; the flowers are white, standing upon long stalkes like the first, but usually more together, and without sent like them: the berries that follow are like the first, and so are the rootes.

5. *Polygonatum latifolium minus.* Small *Salomons* Seale.

This small *Salomons* Seale hath a lower stalke, scarse a foote high, not bending downe so much as the first, but having such like leaves thereon, and in the same manner, yet somewhat harder or stiffer: the flowers come forth at the foote of the leaves in the same fashion, but are larger, standing upon short footestalkes, and but one upon a stalke, without sent like the first, the berries and roots differ not also from the first.

6. *Polygonatum latifolium ramosum sive quartum Clusii.* Broad leafed branched *Salomons* Seale.

This branched *Salomons* Seale riseth up usually with a crooked or bending stalke, about a foote or more long, having one or two or three branches sometimes issuing out from the sides thereof, at the joynts whereof stand severall leaves as in the former sorts, and somewhat like them also, being somewhat large and long, but tenderer and softer and not hoary underneath, compassing the stalke at the lower end where it is broadest, like the leaves of Thoroughwax: underneath every leafe & at the sides of them also at the joynts commeth forth one white flower, ending in six corners, spotted with blackish spots on the inside, standing on a crooked long and pendulous footstalke which smelleth pretty and sweete: after the flowers are past there come in their places three square berries greene at the first, which when they grow ripe are somewhat longer then before, and equall a small berry of the *Cornus mas* or the Cornell Cherry in bignesse almost, and of a reddish colour, having many whitish kernells within them: the roote is not tuberous like the former sorts, but slender and knotty, and of a paler colour, shooting forth into many nodes or knotts, with divers long fibres and strings fastned thereto, the stalkes dying yearely and new rising up in the Spring.

7. *Polygonatum Virginianum.* *Salomons* Seale of *Virginia*.

This *Salomons* Seale, differeth from the former in three principall parts, that is first in the rootes, which are in these slender, long, and creeping like as most of our *Virginian* plants are, and shooting up stalkes round about, and not tuberous as in the former; then in the flowers, which in this are not set at the foote of the leaves as in the other (yet the leaves are of the same fashion, and stand one above another, upon a single upright stalke, and

7. *Polygonatum Virginianum.* *Salomons* Seale of *Virginia*.

8. *Polygonatum racemosum Americanum.* Cluster like *Salomons* Seale of *America*.

branched about a foote or halfe a yard high, but not of ſo ſad a greene colour not diſcouloured underneath) but at the very toppe of the ſtalke many being ſet together, which are whiter and ſmaller, and nothing ſo long and pendulous, ending in fine ſmall pointed leaves: and laſtly in the beries which in this are ſmaller then in any of the former, and of a moſt orient red or ſcarlet colour, (which made them at the firſt to bee taken for Chermes or Scarlet berries where they are naturall, and thought fit to dye withall, but found unprofitable) which while they are white, and before they become ripe have ſix blacke ſtrakes on every of them equally diſtant, but are quite worne out being ripe, within which are contained white, hard, ſtony graines or ſeedes like the other: *Iacobus Cornutus* of *Paris* in his *Canadenſium plantarum hiſtoria* maketh hereof two ſorts, one he calleth *Fertile*, the other *Sterile*, when as they are both but one ſort; however happening one may be more apt to beare berries then another, for that which I have in my Garden that never bore berries, roſe from the ſeede of thoſe berries that were brought us from *New-England*.

8. *Polygonatum racemoſum Americanum.* Cluſter like *Salomons* Seale of *America*.

This plant ſhooteth up a round browniſh ſingle ſtalke, and ſometimes parted or branched, about two or three foote high, ſet with many very faire broad leaves, ſome ribbes being of a reddiſh others of a ſad greene colour, harder then others, and compaſſed about the edges with a rougher and darker liſt: at the toppes of the branches ſtand in open cluſters many ſmall pale coloured threds like unto the Vine Bloſſomes, which paſſing away there ſucceede ſundry ſmall berries, compoſed like a cluſter of Grapes, and each of the bigneſſe of a Iuniper berry, yellowiſh before they be ripe, and finely ſpotted with blood red ſpeckles, which after they have long ſo abidden are worne out by the ripening of them, and change red like a Cherry, whoſe pulpe or juice is ſweete, and containe within them ſmall white rounidiſh ſeede: the roote is thicke, white, tuberous, long and joynted as it were by diſtances, with ſundry fibres thereon.

9. *Polygonatum perfoliatum Braſilianum.* *Salomons* Seale of *Braſſil*.

The *Salomons* Seale of *Braſil* hath an upright ſtraked ſtalke, about a cubit high, whereon are ſet leaves one above another, very large, about foure inches long and two inches broad, of a pale greene colour, full of ribbes, tender and not hard, which compaſſe the ſtalke at the lower end, where it is broadeſt like unto Thoroughwax, that the ſtalke ſeemeth to goe thorough them: the flowers alſo (which ſtand in the ſame manner that the ordinary ſorts doe) are much larger then any of the former, conſiſting of five narrow white leaves two inches long a peece, ſtanding at the ends of very ſmall and long footeſtalkes: the berries and rootes are not ſet forth by mine author.

10. *Polygonatum ramoſum perfoliatum flore luteo majus & minus Americanum.*
The greater and leſſer thorough leafed yellow *Salomons* Seale of *America*.

This *Salomons* Seale hath a ſlender ſmooth ſtalke or two, halfe a foote high, parted about the middle into two branches, and each of them againe into others, the greater ſort having faire, broad and long very pale greene ribbed leaves, compaſſing the ſtalke wholly at the bottome, the ſmaller ſort much narrower and ſmaller: at each of

10. *Polygonatum ramoſum perfoliatum flore luteo majus et minus Americanum:* The greater and leſſe thorow leafed yellow *Salomons* Seale of *America*.

11. *Polygonatum Anguſtifolium.* Narrow leafed *Salomons* Seale.

the

the joynts with the leaves,and at the toppes alſo ſtand the flowers ſingly in each ſort, compoſed of ſix long and narrow yellow leaves hanging downewards, in the middle whereof is a crooked head or horne, compaſſed with ſix yellow threds or chives; when the flower is paſt, the footeſtalke thereof riſeth up,bearing that crooked or horned three ſquare thicke skinny cod on the end, having whitiſh ſeede within it: the roote is nothing ſo thicke or white as the eight, but faſtned by many ſtrings in the ground.

11. *Polygonatum anguſtifolium.* Narrow leafed *Salomons* Seale.

The narrow leafed *Salomons* Seale ſhooteth forth divers upright ſtalkes, about a foote high, bending downewards at the toppes without any branches at all upon them, whereon ſtand at ſeverall joynts and ſpaces, foure or five and ſometimes ſix long and narrower greene leaves then they of the former, being ſmooth and ribbed or full of veines: at the ſaid joynts with the leaves come forth two or three ſhort ſtalkes, with whitiſh greene flowers at the ends of them,like unto the firſt, after which come round berries red when they are ripe, more pulpie or juicie then the laſt, conteining hard white kernells within them like the reſt: the roote is tuberous like the former ordinary ſorts,branching forth at the ſides like them.

12. *Polygonatum anguſtifolium ramoſum.* Branched ſmall *Salomons* Seale.

This ſmall *Salomons* Seale is in moſt things like the laſt, as in rootes, leaves, flowers and berries, the chiefeſt difference conſiſteth in this, that it brancheth forth at every joynt on the maine ſtalke on both ſides thereof, and hath the leaves ſomewhat ſmaller and narrower, yet ſet in the ſame manner, and the flowers ſomewhat ſmaller alſo,ſtanding on ſhort footeſtalkes.

The Place.

The firſt is frequent in divers places of our Land, as beſide thoſe that *Gerard* hath named, it groweth in a wood two miles from *Canterbury* by Fiſhpoole hill, as alſo in a buſhie Cloſe belonging to the Perſonage of *Alderberry* neare *Clarindon*, two miles from *Saliſbury*, the next Cloſe thereunto is called *Speltes*, and in *Cheſſon* wood, on *Cheſſon* hill, betweene *Newington* and *Sittingburne* in *Kent*: the other ſix following it, and the two laſt grow in *Germany*, *Auſtria*, and the parts thereabout: the ſeventh was brought both out of *Virginia* and *New-England*, by ſome Marriners that had thought they had beene the Scarlet or Kermes berries as I ſayd before, from whoſe ſeede ſprang with me firſt, as I thinke in this kingdome, and brought ſuch plants as I have expreſſed in the deſcription: the eighth and tenth were brought from *Canada* by the *French*: the ninth groweth in *Braſſill*, and from thence brought and communicated to *Bauhinus* by Dr. *Burſerus*.

The Time.

They flower about *May*, and the *Virginia*, *Braſſill* and *American* ſorts not untill *June* and *July*, the berries of the *European* ſorts are ripe in *September*, and continue on the ſtalkes untill the froſts rot the ſtalkes, and they fall downe, and periſh with all above ground, the roote abiding ſafe, and ſhooting a new every yeare: the *Virginian* ſort hath ſuch red berries as are expreſſed in the deſcription, but it never bore berries in our Land that I know of: but the other *Americans* beare berries about *September*.

The Names.

It is called in Greeke πολυγόνατον *Polygonatum*, and ſo in Latine alſo, *A radicis geniculorum frequentibus nodis*, of the many nodes and knots in the roote: it is uſually called *Sigillum Salamonis*, for the cauſes ſet downe in the deſcription of the firſt, and of ſome *Scala cœli*. *Ioannes Monardus* tooke it to bee *Secacul* of the *Arabians*, but without all ſhew of reaſon almoſt: the *Italians* in ſome places call it *Polygonato*, and *Ginochietto* in others, and in *Hetruria* or *Florence Fraſſinella*, but for what reſpect I know not,not having any likeneſſe or affinitie with *Fraxinus*, from whence the name ſhould be derived, the *French Genicoliere* of ſome, and *Seau*, or *Signet de Salomon* of others: the *Germans Weiſſwurtz*, *id eſt*, *radix alba*, of the *Dutch Salomons Seghel*, and wee in *Engliſh Salomons* Seale moſt uſually, but in ſome countries the people call it Ladder to Heaven, according to the Latine name *Scala cœli*, which was anciently knowne in the Apothecaries ſhoppes, from the forme of the ſtalke of leaves, one being ſet above another. The firſt is called *Polygonatum* generally by all writers almoſt, ſome calling it *Latifolium*, ſome *majus* and ſome *vulgare*, and ſome *Sigillum Salomonis*. *Anguilara*, *Cæſalpinus* and *Caſtor Durantes* following their owne country name, call it *Fraſſinella*, confounding it with the *Dictamnus albus*, which is called *Fraxinella*: the ſecond is the firſt *Polygonatum latifolium* of *Cluſius*, which *Camerarius in horto* calleth *Polygonatum Pannonicum*, the third is *Cluſius* his ſecond *Polygonatum latiore folio*, which *Cordus* in his Hiſtory of plants calleth *Polygonatum anguloſam*: the fourth is the third *Polygonatum Latiore folio* of *Cluſius*, which *Bauhinus* calleth *Polygonatum latifolium Ellebori albi foliis*: the fift *Bauhinus* in his *Pinax* and *Prodromus* calleth *Polygonatũ latifoliũ minus flore majore*. The ſixt is diverſly called; *Matthiolus* ſetteth it forth for *Laurus Alexandrina*, whom *Camerarius* citeth and *Cluſius* reproveth in that it anſwereth not thereunto, as you ſhall heare more amply in the next Chapter, both by the deſcription and explication. *Iohannes Mollinæus* that ſet forth the great Herball of *Dalechampius* generally called, *Lugdunenſis*, taketh it to be *Hippogloſſum* of *Dioſcorides*; whom *Cluſius* alſo taxeth for it, ſhewing that howſoever the Text of *Dioſcorides* (if corrupted) be amended, yet this cannot be it, becauſe it wanteth thoſe *ligulæ* ſmall tongues, that are growing upon the leaves of *Hypogloſſum*, as you ſhall heare by and by, and that this is not perpetually greene as the *Hypogloſſum*, but dyeth downe to the roote every yeare, ſhooting footh new ſtalkes in the Spring, and therefore *Cluſius* ſaith that it cannot be better referred then unto the kinds of *Polygonatum*, unleſſe as he ſaith it might be the *Idæa radix* of *Dioſcorides*, wherein as he ſaith becauſe he is ſo briefe, nothing can be affirmed for certaine; yet I certainely thinke it anſwereth very fitly thereunto, both in face an vertues: *Lobel* calleth it in his obſervations *Polygonato Affinis planta*, and *Cæſalpinus Ruſco affinis tertia*, *Gerard* hath two figures hereof, and two deſcriptions, as if they were two ſeverall plants, which are his fourth and fift, by the name of *Polygonatum ramoſum*, and *acutum*, the one being the figure of *Matthiolus* his *Laurus Alexandrina*, and the other of *Cluſius*, for they expreſſe but one plant, no other diverſitie thereof to bee found that I can learne. *Bauhinus* calleth it *Polygonatum latifolium ramoſum*: the ſeventh is as I ſayd of mine owne nurſing and naming: the eighth and tenth are ſo called by *Cornutus* as they are in the titles: the ninth *Bauhinus* in his *Pinax* and *Prodromus* calleth *Polygonatum latifolium perfoliatum Braſilianum*: the eleventh is called *Polygonatum minus* by divers, and generally *Polygonatum anguſtifolium*, and *tenuifolium* by all others. *Thalius* calleth this *Polygonatum tenuifolium majus*, as he doth the laſt *tenuifolium minus*, which *Cluſius* and *Bauhinus* call *Polygonatum anguſtifolium ramoſum*.

The Vertues.

The roote of *Salomons* Seale is of chiefeſt uſe,and hath a mixt property as *Galen* ſaith, having partly a binding, and partly a ſharpe or biting quality, as alſo a kinde of loathſome bitterneſſe therein, hardly to be expreſſed,whereby it is of little uſe in inward medecines; which ſharpeneſſe and loathſomeneſſe we hardly perceive in thoſe that grow with us: yet ſome authors doe affirme that the powder of the herbe or of the ſeede purgeth flegme and viſcous humors very forcibly, both upward and downeward; it is ſaid alſo that the roote chewed in the mouth draweth downe much rheume out of the head, and put up into the noſtrills cauſeth ſneeſing: but it ſerveth as he and *Dioſcorides* both ſay, and all experience doth confirme, for wounds,hurts and outward ſores, to heale and cloſe up the lippes of thoſe that are greene and freſh made, and to helpe to dry up the moiſture and reſtraine the flux of humors of thoſe that are old: it is ſingular good to ſtay vomitings and alſo bleedings whereſoever,as alſo all fluxes in man or woman,whether it be the whits or reds,or the running of the reines in men;alſo to knit any joynt that doth grow by weakeneſſe,to be often out of place,or by ſome cauſe ſtayeth but ſmall time therein when it is ſet;as alſo to knit and joyne broken bones in any place of the body;the roots being bruiſed and applyed to the place, yea it hath by late experience beene found that the decoction of the roote in wine, or the bruiſed roote put in wine or other drinke, and after a nights infuſion ſtrayned hard forth and drunke, hath holpen both man and beaſt whoſe bones have beene broken by any occaſion, which is the moſt aſſured refuge of helpe to the people in divers countries of this Land, that they can have: it is no leſſe effectuall to helpe ruptures and burſtings, to be both inwardly taken, the decoction in wine, or the powder in broth or drinke, and outwardly applyed to the place: the ſame alſo is availeable for inward or outward bruiſes, falls or beatings, both to diſpell the congealed blood, and to take away both the paines and the blacke and blew markes that abide after the hurt: the ſame alſo or the diſtilled water of the whole plant uſed to the face or other part of the skinne, cleanſeth it from morphew, freckles,ſpots or markes whatſoever, leaving the place freſh, faire and lovely, which the *Italian* dames as it is ſaid doe much uſe.

CHAP. CIIII.

Laurus Alexandrina. The Laurel of *Alexandria.*

THere hath beene ſo great varietie of opinions among our moderne writers concerning the Laurell of *Alexandria*, what plant ſhould be the right of *Dioſcorides*, ſome ſhewing one and ſome another,and ſcarſe one the true, that I much doubt whether this that I ſhall here ſhew you in this Chapter, will be taken and judged to be the genuine plant by many, who peradventure contemning my opinion may thinke me ſooner to erre and be deceived, then ſo many learned men before me, that have had contrary opinions, but notwithſtanding the diverſity of conceits in many,I will endeavour to enrich the treaſury of the Phyſicall Commonwealth,with my ſmall two poore mites,(*cupiat qui capere poteſt*)reading and knowledge

1. *Laurus Alexandrina genuina.*
The true Laurell of *Alexandria.*

2. *Chamedaphne vera Dioſcoridis.*
The true Dwarfe Laurell of *Dioſcorides.*

by

by the daily converſation among plants, the chiefeſt I can get to enable my judgement. I muſt likewiſe in this Chapter ſhew you another plant being like unto it, which *Matthiolus* ſetteth forth for another ſort of *Laurus Alexandrina*, but I entitle *Chamædaphne vera Dioſcoridis*, being much controverted alſo, for ſuch reaſons as you ſhall heare by and by.

1. *Laurus Alexandrina gennina.* The true Laurell of *Alexandria*.

The true Laurell of *Alexandria* is very like the *Hippogloſſum* of *Dioſcorides*, Horſe tongue or double tongue, for the manner of growing, riſing up from an hard ſtringy roote, knotted at the head, with many greene ſtalkes of leaves ſtanding on both ſides thereof, the lower being larger then the upper, which are ſomewhat broad and round yet pointed at the end with many ribbes therein, and of a paler greene colour then the Horſe tongue, but almoſt as hard in handling: from the middle rib of the leafe about the midſt of it on the upper ſide, there ſhooteth forth a ſmall whitiſh greene flower ſtarre faſhion, ſtanding upon ſo ſhort a footeſtalke that it ſeemeth to have none, which being paſt a ſmall round berrie ſucceedeth in the place, which will bee very red when it is ripe, wherein is contained a white hard ſeede like unto thoſe of the Butchers Broome.

2. *Chamædaphne vera Dioſcoridis.* The true Dwarfe Laurell of *Dioſcorides*.

This dwarfe Laurell groweth up with divers ſtalkes and leaves ſet thereon one above another in the ſame manner that the former doth, but the leaves hereof are not ſo broad and ſhort as they, but longer and narrower, and of a little deeper greene colour on the upper ſide, and paler underneath, full of ribbes or veines alſo, without any ſmall leafe or tongue ſuch as the Horſe tongue hath, elſe ſomewhat like to it: this hath flowers and red berries in the middle of the leafe, and upon as ſhort a ſtalke as the former, but on the under ſide of the leafe for the moſt part, which may well make it ſeeme another ſort of the *Laurus Alexandrina*; and for that cauſe I thinke *Dioſcorides* joyneth the *Ruſcus*, and *Camædaphne* ſo neare unto the *Laurus Alexandrina*, the one before it the other after, for the likeneſſe the one unto the other.

The Place.

Both theſe grow naturally on certaine hills in *Italy*, and for their raritie and uſe brought into their gardens there, from whence we have received them: the firſt I had by the meanes of Dr. *Flud*, one of the Phiſitions of our *London* Colledge, who among many other rare plants he gathered in the garden of the great Duke of *Florence* at *Piſa* and elſe where had this alſo: the other I had by the meanes of my good friend Maiſter *Iohn Tradeſcant* with whom it groweth, having longer and not ſo broad round leaves as the former.

The Time.

They ſcarſe beare flower much leſſe fruit in our Land, but in the warmer countries, they flower in *Iune*, and the berries are ripe in the end of *September*.

The Names.

Dioſcorides calleth the firſt in Greeke Δάφνη Ἀλεξάνδρεια καὶ ἰδαία, *Daphne, Alexandria* and *Idæa*, and the Latines therefrom *Laurus Alexandrina* and *Idæa*, becauſe it is likely it grew upon the mount *Ida*, which is nigh unto the *Alexandria* of *Troas*. *Marcellus* thought it tooke that name from *Alexander* the great, who at his victories wore it on his head; but that is but his bare opinion without ground or reaſon: the *Idæa radix* is another differing herbe ſet before this many Chapters, which I have ſhewed you in the laſt Chapter, moſt fitly to agree with the *Polygonatum latifolium quartum Cluſii*. Divers have thought that the *Laurus Alexandrina* and *Hippogloſſum* of *Dioſcorides* were both one plant, among whom *Cordus* on *Dioſcorides* is one, but *Matthiolus* and *Cornarius* doe both confute that opinion, firſt for that it were a needeleſſe thing in *Dioſcorides* to write two Chapters of one herbe, then that *Dioſcorides* maketh no mention of tongues in the *Laurus Alexandrina*, which hee ſpeaketh of in the *Hippogloſſum*, yet *Matthiolus* falleth into as foule an errour himſelfe, in taking that plant to be *Laurus Alexandrina*, which *Cluſius* calleth *Polygonatum latifolium quartum*, as is ſhewed in the Chapter before, but *Cluſius* ſheweth that whether he meane his *Polygonatum* or any other plant by the figure which he exhibiteth for it, it cannot be *Laurus Alexandrina* which by *Dioſcorides* his Text is a plant whoſe berries grow ἐν μέσοις in the middle of the leaves (and *Matthiolus* quoteth his owne Copie in the Margent to bee ſo) which that plant hath not, but *Theophraſtus lib.* 1. *cap.* 16. and *lib.* 3. *cap.* 17. expreſſeth it more fully by the Greeke word ἐμφυλλόκαρπον: the figure of this *Laurus Alexandrina* is extant in no other author that I know of, but in *Lobel* his *Appendix* to the *Adverſaria*, who as he there acknowledgeth had it from me (as he had many other plants alſo) which he there ſet forth, and I am verily perſwaded is the true *Laurus Alexandrina* of *Dioſcorides*, who maketh the leafe thereof to be like thoſe of *Ruſcus*, whereunto the leaves of this is more like then of the next: the ſecond which I here ſet downe for the *Chamædaphne vera* of *Dioſcorides*, is the *Laurus Alexandrina altera* of *Matthiolus* and *Laurus Alexandrina* of *Columna*, whom *Lugdunenſis*, *Tabermontanus* and *Cluſius* follow, and *Bauhinus* calling it ſo alſo, thinketh that of *Lobel* and this to be both one, which his eyes might bee judges, the one having a rounder the other a longer leafe are divers. The *Matthiolus* of *Bauhinus* ſheweth for *Chamædaphne* that plant which he calleth in his *Pinax Lyſimachia Chamænerion dicta latifolia* or *Delphinum baccinum* of *Lobel*, but quoteth it there to bee miſſe ſet. *Camerarius* his *Epitome* of *Matthiolus* ſetteth forth another figure for his *Chamædaphne* which is much ſuſpected by divers to be counterfet, a fiction of *Matthiolus* owne braine (many ſuch tricks he uſeth in his workes) no ſuch plant being knowne. *Cæſalpinus* calleth it *Ruſco affinis altera*. *Guilandinus* and *Columna* tooke *Chamædaphne* of *Dioſcorides* and his *Laurus Alexandrinus* to be both one, when as his deſcriptions doe evidently vary, expreſſing two ſeverall herbs; the leafe hereof he compareth to a Bay leefe, whereunto it hath more reſemblance then the former, for this is not ſo broad and ſhort as it, but longer and narrower as the bay leafe is: further *Dioſcorides* ſaith, it beareth *fructum annexum folijs*, which cannot be better underſtood to bee joyned to the leaves, then growing upon them. I doe confeſſe that in my former booke I did ſomewhat adhere to *Lobels* opinion, that *Chamælea* or *Meſereon* might be the *Chamædaphne* of *Dioſcorides*, yet I there ſhewed ſome let therein why it ſhould not, but now upon better conſideration and examination of the particulars, both forme and vertues, I cannot finde any plant to agree better with *Dioſcorides* his *Chamædaphne* then this: Let the criticke carper examine this animadverſion, but let the judicious convince me and I will yeeld.

The Vertues.

Galen in 6. *ſimpl. medic.* ſaith that *Laurus Alexandrina* is of a hot temperature ſharpe and ſomewhat bitter in taſt, which being drunke provoketh Vrine and womens courſes, *Dioſcorides* ſaith it haſteneth the hard and ſore travailes

of women in childbearing: a decoction made of the herbe and rootes in wine, is very good for women to ſit over the hot fumes, as alſo to have it injected, or the places bathed for the falling downe of the mother, to ſettle it in the right place againe: the ſaid decoction, or the powder of the herbe and rootes are accounted ſingular good to dry up the moiſture of old Vlcers of long and hard curation, to cleanſe them and the more ſpeedily to performe their healing: the faculties of the other are by *Galens* judgement like to thoſe of the former, and *Dioſcorides* ſaith it eaſeth the paines of the head, and the heart burning, as alſo the torments of the belly, being drunke with wine, and provoketh urine and womens courſes.

CHAP. CV.

Hippogloſſum ſive Biſlingua. Horſe tongue or double tongue.

THe Horſe tongue or double tongue is very like unto the former two plants, ſet forth in the laſt Chapter, for the manner of growing, for this ſhooteth forth divers hard ſtalkes with leaves on them, one above another as they doe, and much about the ſame length: the leaves likewiſe for the forme are but little differing, being ſomewhat harder in handling, narrower & longer, and ſharper pointed, with ribs running through them: but this hath a ſmaller leafe or tongue, growing upon the greater from the middle ribbe, and about the middle of the leafe on the upperſide, which maketh it to differ from all other plants that grow upon the ground that I know, and from thence tooke the name of double tongue: under the ſmaller leafe at the bottome where it joyneth to the greater, commeth forth one ſmall whitiſh greene flower, and ſometimes two, ſtanding upon ſhort footſtalkes, where afterward ſtand the berries, which when they are ripe are very red, very like unto the berries of the Yew tree, wherein is a white hard ſeede like the other: the roote conſiſteth of many long hard whitiſh ſtrings growing from a head. *Fabius Columna* maketh mention of another ſort with larger tongues upon the leaves then the former, which is as he ſaith much more rare to finde.

Majoribus liguis.

Hippogloſſum ſive Biſlingua.
Horſe tongue or double tongue.

The Place.

It groweth upon hills and in woods in divers places both of *Italy* and *Germany*, but is onely cheriſhed in gardens with us.

The Time.

It flowreth in *Iune*, and the berries are ripe in the end of *September*, in the naturall places as in the warmer countries, but I could never learne that any hath ſeene it beare his fruit in our Land.

The Names.

It is called in Greeke ἱππόγλωσσον *Hippogloſſum*, ἱππὸ *ſæpiſſime magnis plantis datur, vel quia equinã linguam imitatur vel grandẽ*, but others think it ſhould be more truly called ὑπόγλωσσον *Hypogloſſum*, becauſe of the ſmall leaves like ſmall tongues, growing upon the greater: the Latines keepe the name and call it *Hippogloſſum* or *Hypogloſſum*, and ſome to expreſſe the Greeke name more fully in Latine *Biſlingua*, two tongues or double tongue, ſome *Lingua Pagana*, and of *Apuleius Victoriola*: it is called alſo *Bonifacia* by *Anguilara*, and *Uvularia* by *Brunfelſius*, *Lonicerus*, *Tabermontanus* and others. *Fuſchius* calleth it *Daphne Alexandrina*, and *Laurus Alexandrina*, as *Tragus* and divers others doe, and *Cluſius* himſelfe confeſſeth he knew no other *Laurus Alexandrina*, untill *Simon de Tovar*, a *Spaniſh* Phiſition did ſend him a branch, with the berries of the right *Laurus Alexandrina* to ſee, which had no tongues or ſmall leaves at all, and was as I take it the *Chamædaphne* I have ſhewed you before, and therefore he called this *Laurus Alexandrina Theophraſti ſecunda*. *Caſalpinus* calleth it *Ruſco affinis prima*. *Columna* maketh it to bee *Idæa radix Dioſcoridis*, and *Dalechampius* to bee *Laurus Taxa* of *Pliny*, which to be ſo, he contendeth very ſeriouſly, as it is ſet downe by *Lugdunenſis*, that *Pliny* in his 15. Booke and 30. Chap. numbreth up the ſeverall ſorts of true Bayes, and then mentioneth thoſe that are ſo called, eyther of the Greeke or Latines from ſome likeneſſe of the leaves, as *Laurus Tinus*, *Laurus Taxa*, *Chamædaphne*, *Daphnoides*, and *Laurus Alexandrina*, but *Monardus* thinketh that in ſtead of *Laurus Taxa*, *Laurus Fraxinea*, or *Fraxinus Laurea* ſhould be read, againſt which he conteſteth, and ſheweth that no author ever made mention of any ſuch Bay, and that *Pliny* in the place before cited, giveth a ſpeciall note of *Laurus Taxa*, that is to bee fit for trailes or borders in Gardens, and that it hath a ſmall leafe like unto a jagge or torne peece of a leafe growing in the middle of the other leafe; and further that the appellation or name doth fitly agree therewith, being called a Bay from the forme of the leafe, and *Taxa* from the red berries like unto thoſe of the Yew tree called *Taxus*. This I have related to ſhew his judgement and reaſons, that others may allow or diſallow thereof, as they ſhall ſee cauſe, but for mine owne part, I thinke that *Pliny* in this as in divers other plants giveth two names and two deſcriptions of one and the ſame herbe, following the ſeverall authors hee read, as *Dioſcorides*, *Theophraſtus* and others, and often confoundeth them, and often alſo addeth or detracteth of his owne minde, or the opinion of others in his time what he thought good, for in his 27. Booke and 11. Chapter hee maketh mention of *Hippogloſſum*

gloſſum, which he ſaith hath leaves like unto the wild Mirtle having a ſmall leafe like a tongue iſſuing from them, which deſcribeth this *Hippogloſſum* as plainely as may be, and as I ſaid before there is not knowne any herbe but this, that hath ſuch ſmall leaves or peeces of leaves growing upon the greater; *Lugdunenſis* ſheweth that *Dalechampius* tooke it to be the *Chamedaphne* of *Dioſcorides*, upon this ground peradventure that *Dioſcorides* maketh no mention of *Hippogloſſum*, but if he had ſo meant, he could not have forgotten theſe ſmall leaves or tongues upon the greater: the *Italians* call it *Biſlingua* and *Bonifacia*, the *Spaniards Lengua de cavallo*, the *French Biſlingua*, the *Germans Zapflinkraut*, the *Dutch Tonghenbladt*, and wee in *Engliſh* Horſe tongue and double tongue.

The Vertues.

Horſe tongue is thought to be hot and dry in the ſecond degree. It is held to be the moſt powerfull herbe that is, to helpe the ſuffocations and others diſeaſes of the mother, to take the powder of the dryed leaves or roots in wine, broth, or other drinke, for it will ſpeedily give eaſe: three or foure drammes of the ſaid powder taken in ſweet wine procureth a ſpeedy delivery, and driveth forth the afterbirth, provoketh the courſes and Vrine when they are ſtopped, and expelleth the ſtone in the reines and kidneys: if a dramme or two of the ſaid powder be given to drinke in wine or broth for ſome certaine dayes together, it will helpe thoſe that have a rupture or are burſten, and for this purpoſe it is accounted by divers that there is no helpe better, but although it may bring ſome paines at the firſt takings, yet by continuance it will knit and heale the part, yet they muſt uſe their truſſe for a good while after, as well as during the cure: it is alſo good for thoſe that have ſome imperfection in their ſpeech, ſo as it be not naturall: it helpeth alſo the ſores in the mouth and throat, and to ſettle the palate of the mouth in its place, that is ſubject often to fall downe by reaſon of two much moiſture: it is likewiſe of ſingular good uſe in old and filthy ulcers, in any part of the body, to dry up the moiſture, and to bring them on the more ſpeedily to be healed, either the powder of the leaves or rootes to bee uſed alone, or with other things put unto them, or the decoction to waſh them or inject into them.

CHAP. CVI.

Geranium. Cranes bill or Storkes bill.

DIoſcorides ſetteth forth but two ſorts of Cranes bills: *Pliny* addeth a third, *Matthiolus* hath ſix, others have encreaſed the number ſtill more and more; but our age hath found out many more, whereof I have ſhewed you in my former booke divers ſorts, ſuch as are of moſt delight and beauty, fit to furniſh ſuch a garden as you there finde them; of none of theſe doe I intend to ſpeake againe, having given you their deſcriptions, &c. in that place, I will onely give you ſome of their figures which ſhall ſuffice. There are many other fit to be knowne, which ſhall follow in this place, and becauſe I would obſerve the ſame method I

1. *Geranium bulboſum Doctoris Pennæi.*
Doctor *Penny* his bulbous Cranes bill.

2. *Geranium nodoſum.*
Knotted Cranes Bill.

have

have formerly done, I will diſtribute them into three rankes or orders, the firſt ſhall be of thoſe that beare broad leaves, like the Aconites or Crowfoot: the next ſhall be of ſuch as have round leaves like unto Mallowes, and the laſt of thoſe that have their leaves much cut in and jagged.

Gerania Batrachia. Crowfoote Cranes bill.

1. *Geranium bulboſum Pennæi ſive grumoſa radice.* Doctor *Penny* his bulbous Cranes bill.

This Cranes bill hath for the roote many ſmall long bulbes or kernells iſſuing from a long whitiſh roote, and divers ſmall fibres ſet both above them and at their ends: the ſtalke is about a cubit high, with joynts or knees in ſeverall places, at each whereof come forth ſmall ſhort and pointed leaves, as alſo two great leaves upon long footeſtalkes, divided into five parts, each of them cut in ſomewhat on the edges; at the toppes of the ſtalkes and branches, and from the upper joynts likewiſe come forth divers flowers together, each ſtanding on ſhort footſtalkes, conſiſting of five leaves a peece, of a reddiſh purple or roſe colour, not ſo large as thoſe of the Crowfoote Cranes bill.

2. *Geranium nodoſum.* Knotted Cranes bill.

The knotted Cranes bill ſendeth forth certaine leaves upon long footſtalkes from the roote, which is knotted and jointed, with divers long fibres growing therefrom, among which riſe up two or three ſlender ſtalkes a foote high, with great joynts like knees ſtanding forth, and reddiſh; toward the bottome there uſually ſtand two leaves upon long footeſtalkes at a joynt cut into three parts, yet ſhewing to bee five, for that the two loweſt are cut in a little: from the uppermoſt joynt of leaves come forth two flowers for the moſt part and no more, ſtanding upon longer footeſtales made of five leaves a peece, dented in the middle like a Mallow, of a purpliſh colour, with veines of a deeper purple running there through, having a reddiſh umbone in the middle, cut into five parts at the toppe, which being paſt there come in their places long beake heads, ſomewhat great at the bottome, whereon the ſeeds are ſet, as in the other ſort of Cranes bills.

3. *Geranium pullo flore.* Darke red Cranes bill.

The darke red Cranes bill hath divers broad ſpread, ſoft, and ſomewhat hairy leaves riſing immediatly from the roote, upon long footſtalkes cut into five or ſix or ſeven deepe gaſhes or diviſions, with a blackiſh ſpot at the bottome of every one of them, and dented alſo about their edges: the ſtalke riſeth up about two foote high, ſpotted with many blooddy ſpots, and is ſtrong ſomewhat hairy, and parted into three or foure branches with ſuch like leaves on them but leſſer, and at their ends two or three flowers a peece, each of them conſiſting of five leaves cut in on the edges (which is a faſhion different from all other Cranes bills) of a deepe red colour almoſt blackiſh, and in the middle a long ſtile with many writhed threds about it: the ſeede that followeth is browne, & like unto the other ſorts: the roote hath great reddiſh heads above, and many long ſtrings and fibres deſcending from it.

4. *Geranium Batrachoides minus,* Small Crowfoote Cranes bill.

This Crowfoote Cranes bill is ſomewhat like the other deſcribed in my former booke, having large rough and hairy leaves upon long footſtalkes, cut in more deepely on the edges, and dented alſo round about, the ſtalke is a

3. *Geranium pullo flore.*

ovell

foote

5. *Geranium Moscoviticum purpureum.*
Purple Cranes bill of *Muscovy*.

6. *Geranium Batrachoides alterum longius radicatum Lobelij.*
Long rooted Crowfoot Cranes bill.

foote and a halfe high, branched into divers parts, with leſſer divided leaves at the joints up to the toppes, where the flowers ſtand very like unto the other, but leſſer, and of a reddiſh purple colour: the ſeede that followeth is like the other, but ſtandeth upright and turneth not downewards: the roote is ſomewhat thicke and reddiſh at the head with divers ſtrings and fibres thereat.

5. *Geranium Moſcoviticum purpureum.* Purple Cranes bill of *Muſcovy*.

This purple Cranes bill hath broad leaves divided into five parts or diviſions for the moſt part, and dented likewiſe about the edges, ſomewhat reſembling *Geranium fuſcum*, but not fully ſo large, or rather like the *Geranium Romanum verſicolor* but of a deeper greene colour, and with ſome blacke ſpots alſo like them at the bottome of the diviſions of the leafe, the ſtalke riſeth about two foote high, with ſundry tufts of large purpliſh blew flowers tending to red, the ſeede that followeth is almoſt as ſmall as that of the *Roman* ſtriped kinde: the roote ſhooteth forth divers heads whereby it is increaſed, but looſeth all his leaves in winter which the others doe not.

6. *Geranium Batrachoides alterum longius radicatum Lobelij.* Long rooted Crowfoot Cranes bill.

The leaves of this Cranes bill are ſomewhat large but yet leſſe then the other *Batrachoides*, elſe very like, among which riſe ſundry ſtalkes bearing faire and beautifull red flowers of a more excellent red colour then thoſe of the bulbed Cranes bill, ſmelling very ſweet like Muske, and ſeede ſucceeding like the other: the roote is very long and great, with ſmall fibres thereat.

7. *Geranium parvum Salmanticenſe.* Small *Spaniſh* Cranes bill.

This ſmall Cranes bill hath leaves like the ordinary Crowfoot, and ſmall purple flowers, with great heads like the *Candy* Cranes bill, and a ſmall fibrous roote.

The Place.

The firſt as *Cluſius* ſaith grew in *Denmarke* in the countrey of *Hafina*: the naturall place of the ſecond is not expreſſed: the third as *Cluſius* ſaith groweth in ſome parts of *Hungary*: the fourth in other places of *Germany*: the fift in *Muſcovy* brought to us by Mr. *John Tradeſcant*: the ſixt on Mount *Baldus*, and the laſt on the ſtony and barren hills of *Salamanca* in *Spaine*.

The Time.

They all flower in *Iune* and *Iuly*, and their ſeede is ripe quickly after.

The Names.

The Greekes call it Γερανιον *Geranium*, and ſo doe the Latines alſo, but to expreſſe it the more plainely *Gruinalis*, *Roſtrum gruis* or *gruinum* & *Roſtrum Ciconiæ*, from the forme of the ſeedes like a Storke or Cranes bill: the *Italians* call it *Giranio*, and *Roſtro di grue*, the *Spaniards Pica di cigüana*, the *French bec de cigogue*, the *Germanes Storckenſchnabel*, the *Dutch Oyenaeris beck*, and we in *Engliſh* Storkes bill or Cranes bill. The firſt is *Cluſius* his fourth *Geranium*, which he calleth *Geranium bulboſum Pennæi*, and *Bauhinus Geranium grumoſa radice*: the ſecond is *Cluſius* his *Geranium nodoſum*, and *tuberiferum Plateau* alſo, for they are both but one plant, as he ſheweth himſelfe, and I thinke is very like, if not the ſame with the *Geranium Romanum verſicolor ſive ſtriatum*, which is ſet forth in my former booke: the third *Cluſius* calleth *Geranium pullo flore*, which it is likely *Geſner* in *Appendice*

maketh

maketh mention of: the fourth *Camerarius* and *Cluſius* call *Geranium Batrachoides minus*, and *alterum*: the fift hath not beene publiſhed by any that I know, although we have had it long time in our Gardens: the ſixt is called by *Lobel Geranium Batrachoides longius radicatum*, which *Camerarius* calleth *Geranium Macrorhyſon*, and called *Statice Plinij* by ſome as he ſaith, of *Dodonæus Batrachoides alterum*: the laſt is called by *Cluſius Geranium octavum vel Salmanticenſe roſtratum*, but *Bauhinus Geranium parvum folijs Ranunculi*.

The Vertues.

All theſe Cranes bills are drying, binding, and a little hot withall, and are found to be effectuall both in inward and outward wounds, to ſtay bleedings, vomitings and fluxes, eyther the decoction of the herbe, or the powder of the leaves and roots uſed as the cauſe requireth.

CHAP. CVII.

Gerania Malvacea. Round or Mallow leafed Cranes bills.

THe ſecond kind of Cranes bills to be entreated of, is of thoſe that beare round or Mallow like leaves, which ſhall follow.

1. *Geranium tuberoſum minus Camerarij.* Small tuberous Cranes bill.

This ſmall Cranes bill hath divers round leaves very like the ordinary Doves foote, but much leſſe: the flowers likewiſe are very ſmall and reddiſh like thereunto, and ſo are the beake heads with ſeede alſo: the roote is round, of the bigneſſe of an Haſle nut, without any fibres growing from it, drawing the nouriſhment out of the earth by certaine little trouthes, which are like ſmall hollow parts therein, not abiding to be taken out of the naturall place of its growing, which is in mud walls to be tranſported into gardens, for as *Camerarius* ſaith having often tryed it, it will decay by little and little.

2. *Geranium Columbinum vulgare.* The common Doves foote or Cranes bill.

The common Doves foote or Cranes bill hath divers ſmall round pale greene leaves, cut in about the edges much like unto Mallowes, ſtanding upon long reddiſh hairy ſtalkes, lying in a round compaſſe upon the ground, among which riſe up two or three or more reddiſh joynted, ſlender, weake and hairy ſtalkes, with ſome ſuch like leaves thereon but ſmaller, and more cut in up to the tops, where grow many very ſmall bright red flowers, of five leaves a peece, after which follow ſmall heads, with ſmall ſhort beakes pointing forth, as all other ſorts of theſe kinds of herbes doe, whereby they are knowne to be of this family, how variable ſoever their face or forme of leaves, &c. be.

3. *Geranium Malacoides laciniatum ſive Columbinum alterum.* The other Doves foote.

Of this kind there is another ſort, whoſe leaves are greener, not ſo round, and ſomewhat more cut in on the

The common Doves foote or Cranes bill.

Geranium bulboſum vulgare.
The common bulbed Cranes bill.

edges

6. *Geranium Althæodes majus.*
The greatest Marsh Mallow leafed Cranes bill.

9. *Geranium Saxatile.*
Rockie Cranes bill.

edges, making thē leafe seeme of divers parts more then the former, or like the Vervaine Mallow but somewhat lesser, otherwise like it in flowers, weake leaning stalkes, &c.

4. *Geranium Malacoides seu Columbinum minimum.* The least Doves foote.

This is another also very small, not rising above two or three inches with his stalkes; the leaves also flowers, and seede are of a fise eq ıall to the rest, that is very small.

5. *Geranium Malvoides sive Columbinum tenuius laciniatum.* Doves foote with thin cut leaves.

This also is but a small plant not above an handbreadth high, whose leaves are round of the bigneſſe of ones nayle, cut in at the edges into foure divisions, and each of them somewhat cut in also, standing upon long foote-stalkes; the flowers are small, two for the most part and no more standing together, small and reddish like the other, and so is the seede and roote.

6. *Geranium Althæodes majus.* The greatest Marsh Mallow leafed Cranes bill.

The first leaves of this Cranes bill are more round then the other that follow, which are somewhat long, with the roundnesse like unto the Marsh Mallowes, somewhat roundly but a little deepely cut in on the edgs, soft also and of a whiter greene colour almost woolly, the stalkes are more upright and hairy, with such leaves thereon, but smaller longer and a little more cut in on the edges, on the toppes whereof stand small purplish flowers, and after them small beake heads like unto others: the roote is somewhat long and wooddy dying every yeare, and rising againe of it owne sowing.

7. *Geranium Althæodes minus.* The lesser Marsh Mallow leafed Cranes bill.

This other Cranes bill is like the other in all things but smaller and lower, the leaves being a little whiter, thē flowers small and so likewise the seede, that oftentimes wee scarse finde it.

8. *Geranium Alceæ vesicariæ folijs.* *Venice* Mallow leafed Cranes bill.

This *Spanish* Cranes bill spreadeth it selfe very farre with long slender branches, whereon are set at certaine distances many leaves like unto the *Venice* Mallow but more divided, the flowers are small and purplish, after which followeth the seede contained in small vessells; the roote perisheth every yeare. This and the third among a number of other seeds were brought me by *Guillaume Boel* which he gathered in *Spaine* upon my charge; however Mr. *Goodier* getting the seeds from Mr. *Coys*, caused it and divers other things to bee published in his name: notwithstanding I told him the charge was mine that procured it and many other.

9. *Geranium Saxatile.* Rockie Cranes bill.

The rockie Cranes bill is a lesser plant then the ordinary Doves foot, having many small leaves, somewhat cut in on the edges, very greene & shining so like unto a small Sanicle leafe, that it may deceive one, set on reddish stalks; lying on the ground all the Autumne, Winter and Spring untill the Summer, that the stalkes rise up about a span high, or somewhat more, bearing a few leaves on them, and very small purplish red flowers, brighter and redder then

then the Doves foote, which gives very ſmall ſeede, but of the faſhion of the reſt; yet *Camerarius* addeth to *Thalius* deſcription that the ſeede is yellow like *Chamæline* Engliſh Wormeſeede, but without any taſte, wherein ſurely he is much miſtaken, for how could it be *Geranium* then, as both hee and *Thalius* call it; and moreover *Columna* in deſcribing it ſheweth what manner of bills or beake heads it beareth: the roote is ſmall and yellowiſh, yet abideth and periſheth not, but encreaſeth plentifully enough of the ſeede in my Garden.

The Place.

The firſt groweth as *Camerarius* ſaith out of mud walls in divers places of *Germany*, the ſecond commonly in paſture grounds, and by the path ſides every where, and will be in many gardens alſo: the third is found in ſome paſtures alſo, but not frequent: the fourth in the fields about *Rhotomagum* or *Roan* in *Narbone*: the fift in woods about *Mompelier*: the ſixt on Mount *Baldus*, about *Mompelier* alſo, & in other places: the ſeventh in *Spaine*, from whence I had ſeedes brought me: the laſt in ſtony grounds in *Harcynia ſylva*, as *Camerarius* and *Thalius* ſay; and about *Naples* as *Columna* ſaith, but found alſo in our owne countrey by Mr. *John Gordier*, a great lover and curious ſearcher of plants; who beſides this hath found in our countrey many other plants, not imagined to grow in our Land. I wiſh there were many more of his minde, that not hindering their affaires at ſpare times, would be induſtrious to ſearch out and know what the ground bringeth forth, where their occaſions are to be.

The Time.

They all flower in the Summer moneths of *Iune*, *Iuly* and *Auguſt*, ſome more early then other, and their ſeede is ripe quickly after.

The Names.

The firſt is called by *Camerarius Geranium tuberoſum minimum*: the next two ſorts are called generally *Pes Columbinus*, and *Geranium Columbinum*, and ſome *Roſtrum Gruis* and *Gruinum*, and *Roſtrum Ciconiæ*, Storkes bill, yet ſome as *Camerarius* and others note it, call it *Geranium Malvaceum*, and *Balſiminum*, and *Momordica* from thence as *Camerarius* ſaith, eſpecially the greater ſort as *Matthiolus* ſaith, from the *Balſamine* or healing properties as it is likely above the other ſorts, although *Lobel* taxeth him for ſo ſaying. where himſelfe is more worthy of reproofe, in miſtaking the ſecond ſort for the firſt here expreſſed. The common Doves foote is generally held to be the ſecond *Geranium* of *Dioſcorides*, although *Braſavolas* as *Matthiolus* noteth it was miſtaken therein: the *Italians* call it *Roſtro de cicongna*, and *Geranio*: the *Spaniards Pico di cigueñha*: the *French Bec de grue*, and *bec de cicogne*: the *Germans Storkenſchnabel* and *Skarterkraut*: the *Dutch Duyvenvoet*, and wee in *Engliſh* Doves foote, Cranes bill, and Storkes bill: the fouth and fift are of *Bauhinus* addition by the ſame title they beare here: the ſixt is called *Geranium Malacoides* of *Lobel*, and *Altheodes* of *Camerarius*, wherein as I ſaid before he was miſtaken in taxing *Matthiolus*; of *Tabermontanus Geranium Monſpeliacum*, and of *Bauhinus Geranium folijs Althæa* and ſaith that it may moſt fitly agree with the ſecond *Geranium* of *Pliny* (who followeth *Dioſcorides*) which hath as he ſaith more white or woolly leaves then a Mallow: the ſeventh and eighth are of mine owne nurſing up from the *Spaniſh* ſeede, and being of neare affinitie receive alſo their name correſpondent: the laſt is called by *Camerarius Gerainum Saxatile*, and not knowne as he ſaith before his time. *Thalius* mentioneth it in *Harcynia ſylva* by the name of *Geranium* ὑγροκοτύλον and *Columna Geranium alterum montanum ſaxatile rotundifolium*, and *Bauhinus Geranium lucidum ſaxatile*.

The Vertues.

The ordinary Doves foote is found by good experience, and *Lobel* and others note it alſo to bee ſingular good for the winde Collicke and paines thereof in the lower belly, as alſo to expell the ſtone and gravell in the Kidneies, the decoction thereof to be drunke, or to ſit as in a bath therein, or to be fomented therewith: the decoction thereof in wine is an exceeding good wound drinke for any to take that have either inward wounds hurts or bruiſes, both to ſtay the bleeding, to diſſolve and expell the congealed blood, and to heale the parts, as alſo outward ſores ulcers or fiſtulaes perfectly to cleanſe and heale them, and for greene wounds, many doe but bruiſe the herbe and apply it to the place whereſoever it bee, and it will quickly heale them: the ſame decoction in wine fomented to any place pained with the Goute giveth much eaſe: it doth the ſame alſo to all joynt aches or paines of the ſinewes. *Gerard* his experience to be ſingular in ruptures or burſtings (but not as of his owne invention) is knowne to be moſt certaine, whether you take the powder or the decoction of the herbe, for ſometimes together, and helpeth as well young as old folkes, if they continue it the longer.

CHAP. CVIII.

Gerania laciniata. Cranes bills with jagged leaves.

THe third and laſt kind of Cranes bills, is as I ordered it at the firſt, of ſuch ſorts that have their leaves more jagged then the former, as ſhall be ſhewed.

1. *Geranium moſchatum.* Muſke Cranes bill.

The Muſke or ſweet ſmelling Cranes bill hath divers long, winged darke greene leaves lying upon the ground, yet ſomewhat whitiſh by the haires that are thereon cut into many parts or leaves, and each of them cut in on the edges, among which riſe up weake tender ſtalkes, ſcarſe able to ſtand upright, uſually not a foote high, with ſome ſuch like leaves upon them as grow below, but ſmaller and finer cut in at the toppes, and among the upper leaves ſometimes alſo grow divers very ſmall red or crimſon flowers, after which come very ſmall and long beakes or bills with ſeede at the bottome, as all the reſt of the Cranes bills have, which twineth it ſelfe as moſt of them doe: the roote is ſomewhat long with divers fibres thereat; the whole plant and every part thereof above the ground, hath a pleaſant fine weake ſent, which ſome reſemble to Muſke, whereof came the name, but the ſent of true and good Muſke is much differing from it.

2. *Geranium moſchatum inodorum.* Vnſavory Muſke Cranes bill.

There is little difference to be diſcerned betweene this and the former Cranes bill, eyther in growth or bignes, or forme of the leaves or flowers, but chiefly differing in this that it hath no ſent at all wherein reſteth the chiefeſt, if not the onely difference: Of this ſort alſo one hath beene found to beare white flowers, differing in nothing elſe.

Flore albo.

3. *Geranium*

1. *Geranium Moſchatum.*
Muske Cranes bill.

4. *Geranium fœtidum.*
Strong ſented Cranes bill.

3. *Geranium Apulum odorum. Italian* Muske Cranes bill.

The *Italian* Muske Cranes bill hath divers long leaves, and ſomewhat hairy lying on the ground, cut in on the edges ſomewhat like the diviſions of the lower leaves of the *Candy* Cranes bill, ſtanding upon reddiſh footeſtalkes, the two loweſt jagges being greater then the reſt, but thoſe that riſe up with the ſtalke are more cut in, ſomewhat like unto the lower leaves of Coriander, or Fetherfew, but with rounder dents, of a ſweete ſent, as the firſt, whereof it is thought to bee a *ſpecies* of: the ſtalke is jointed and kneed, with two ſuch like leaves at them, but more finely jagged, and at the toppe divers ſmall flowers, of a pale blewiſh purple colour, each ſtanding in a greene hairy huske, wherein afterwards ſtand the heads of ſeeds very like unto the *Candy* kinde, great below and ſmall above: the roote is ſmall and yellow, lifting the head a little above the ground.

4. *Geranium fœtidum.* Strong ſented Cranes bill.

This Cranes bill hath divers hoary greene leaves, finely cut in on the edges into many parts from among which riſe two or three ſlender hairy ſtalkes ſet at the joynts with a few ſmall leaves, and three or foure ſomewhat large reddiſh flowers above, like unto the other ſorts, ſmelling ſomewhat ſweete in our Gardens by the tranſpoſition, but ſtrong in the naturall warmer places, after which come the ſeede ſomewhat long, ſtrong and ſtiffe: the roote groweth downe deepe, of a reddiſh colour on the outſide and white within, which ſmelleth much ſtronger then leaves or flowers, and ſhooteth forth ſundry heads of leaves at the toppe.

5. *Geranium triſte ſive Indicum noctu olens.* Sweete *Indian* Cranes bill.

The rootes of this Cranes bill are tuberous or Aſphodill like, from whence riſe foure or five long and large ſad greene leaves, diverſly cut into many parts, each part jagged on both ſides ſomewhat reſembling the leaves of *Filipendula* but ſofter, the middle ribbe being reddiſh and the reſt ſad greene: the ſtalke is jointed or kneede with the like leaves riſing with it, and at the toppe a tuft of many flowers, like for forme unto thoſe of other Cranes bills, but of a boxlike yellow colour, each leafe having two purple ſpots on them, which being fallen there come ſuch like long beakes as are in the former with reddiſh ſeede on them, the flowers ſmell very ſweete like Muske in the night onely, and not at all in the day time, as refuſing the Sunnes influence, but delighteth in the Moones appearance: it taſteth ſomewhat ſower, and both rootes and leaves are Lettice for the *Indians* lippes.

6. *Geranium Monſpeliacum laciniatum. French* jagged Cranes bill.

The *French* jagged Cranes bill riſeth up with ſundry rough hairy ſtalkes, three or foure foote high, joynted and branched in divers places, with divers leaves thereon cut on both ſides, very like unto thoſe of the Muske Cranes bill: the flowers that ſtand at the toppes of the ſtalkes and branches are ſmall, of a pale purple colour, after which come the ſeede, out of the ſame huske wherein the flowers ſtood before, as is common to all the kinds whatſoever, but the beake heads hereof are very long and hairy, even five inches long, which twine themſelves when they grow ripe, and ſo fall upon the ground.

7. *Geranium Alpinum longius radicatum Pona.* Mountaine Cranes bill with long roots.

This Mountaine Cranes bill hath a very long downe right roote, parted upwards into two or three branched great heads, ſending forth many leaves, divided into five or ſix parts, each whereof is dented with three deepe gaſhes at the end, ſoft alſo and woolly, ſtanding on very long footeſtalkes, covered with ſilver like downe, the flowers ſtand at the toppes of naked ſtalkes, two or three together ſomewhat large and round, yet a little round at the ends, of a pale purpliſh colour with divers reddiſh lines therein, and divers threds in the middle: the ſeede is ſmall and ſtanding on ſhort beake heads.

8. *Geranium Robertianum vulgare.* The common herbe Robert.

The herbe Robert that is moſt common with us, riſeth up with a reddiſh ſtalke, uſually two foot high, having divers leaves thereon, upon very long and reddiſh footſtalkes, divided at the ends into three or five diviſions, and each of them cut in on the edges, ſome with deeper cuts then others, and all dented likewiſe about the edges

5. *Geranium triſte ſive Indicum noctu olens.*
Sweete *Indian* Cranes bill.

Geranium Creticum.
Candy Cranes bill.

7. *Geranium Alpinum longius radicatum Pona.*
Mountaine Cranes bill with long rootes.

8. *Geranium Robertianum vulgare.*
The common Herbe *Robert.*

which oftentimes turne reddiſh: at the toppes of the ſtalke come forth divers flowers, made of five leaves, much larger then the Muske Cranes bill or Doves foote (*Lobel* maketh a difference in the flowers ſome to be larger then others) and of a more reddiſh colour: after which come beake heads as in others, which are not ſmall nor very great: the roote is ſmall and threddy, and ſmelleth as the whole plant elſe doth, very ſtrong almoſt ſtinking.

9. *Geranium Robertianum majus.* The greater herbe Robert.

This herbe Robert riſeth up with divers ſlender hairy reddiſh ſtalkes three foote high, at the joynts whereof ſtand leaves upon ſhorter yet reddiſh footſtalkes, divided at the ends moſt uſually but into three parts, as large or rather more then the former, and turning red likewiſe: the flowers are purpliſh red, and of the ſame bigneſſe and ſo are the ſeede and beake heads, the roote is wholly red both within and without, not ſmelling ſo ſtrong as the former.

The Place.

The two firſt grow wilde in many places of this Land, as well in medowes as waſt grounds, the firſt is cheriſhed for the ſent in Gardens, more then the other, which is found ſometimes upon Heaths, and dry gravelly places, but much ſmaller then in the better grounds: the third was found by *Columna* in *Naples* upon the hills there: the fourth at the North ſide of *Mons lupus* by *Mompelier*: the fift in the *Indies*: the ſixt by *Mompelier* alſo: the ſeventh on mount *Baldus*: the eighth is frequent every where by way ſides, upon ditch banks and waſte grounds whereſoever one goeth, but the laſt is not ſo frequent as the other, yet often ſeene and found.

The Time.

They flower in *Iune* and *Iuly* chiefely, and their ſeede is ſoone ripe after.

The Names.

This is called *Geranium Moſchatum*, *Acus moſchata*, and *Acus paſtoris* of ſome, although the *Scandix* or *Pecten Veneris*, is ſo called alſo, of ſome alſo *Roſtrum Ciconiæ*, and taken to be the *Myrrhida Plinij*: *Matthiolus* maketh it his third *Geranium* in his laſt Edition, but the firſt in his former by the name of *Cicutæ folio*. *Dodonæus Geranium ſupinum*, and *Bauhinus Geranium Cicutæ folio Moſchatum*: the ſecond is called *Geranium gruinum* by *Dodonæus*, and *minus* by *Tragus* and *Tabermontanus*, and by others *vulgatum inodorum*, and *Moſchatum inodorum*: the third is called by *Columna Geranium Apulum Coriandri folio alterum odorum*: the fourth is called by thoſe of *Mompelier* as it is in the title: the fift *Cornutus* calleth *Geranium triſte*: the ſixt is called by *Bauhinus*, *Geranium Cicutæ folio acu longiſſima*: the ſeventh is called by *Pona Geranium Alpinum*, *longius radicatum*: the eighth is generally called *Geranium Robertianum* and *Rupertianū*, and *herba Roberti* or *Ruperti*, *Anguillara* calleth it *Panax Heracleum*: it is certainely taken of many the beſt of our moderne writers to be the *Sideritis tertia Dioſcoridis*, which *Crateuas* he ſaith called *Heraclea*, whoſe leaves are like thoſe of *Coriander*, yet *Columna* taketh the *Diapenſia Sanicle* to be it: the laſt is called by *Lobel Geranij Robertiani altera ſpecies*, by *Dodonæus Geranium gruinale*, and is the *Geranium Violaceum* of *Gerard*, and *Tabermontanus* whom he followeth, the *Germanes* call this *Bludwurtz*, *id eſt*, *Sanguinaria radix*.

The Vertues.

Theſe kinds of Cranes bills are neare the temprature of the former, and may performe all the properties found in them, but the two firſt ſorts here expreſſed are held more availeable for the mother to ſettle it in the place when it is fallen downe. Herbe Robert is not onely commended againſt the ſtone, but to ſtay blood, where or howſoever flowing, and ſo is the laſt alſo, as alſo ſpeedily to heale all greene wounds, and is effectuall alſo in old ulcers, in the ſecret as well as in the other parts.

CHAP. CIX.

Tabacco Anglicum. *Engliſh* Tabacco.

HAve in my former book given you the knowledge of divers ſorts of Tabacco, ſuch as for their flowers ſake might be fit to be nourſed up in gardens: there remaineth one ſort more, which is planted more for the uſe of Phiſicke and Chirurgery then for any other reſpect whereof I meane to ſpeake in this Chapter. It riſeth up with a thicke round ſtalke, about two foote high, whereon doe grow thicke, fat and fleſhy greene leaves, nothing ſo large as the other *Indian* kinds, neither for breadth or length, ſomewhat round pointed alſo and nothing dented about the edges: the ſtalke brancheth forth, and beareth at the toppes divers flowers, ſet in greene huskes like the other, but they are nothing ſo large, ſcarſe ſtanding above the brims of the huskes, round pointed alſo, and of a greeniſh yellow colour: the ſeede that followeth is not ſo bright but larger then it, conteined in the like, and as great heads: the rootes are neither ſo great or wooddy, and periſh every yeare, with the deepe froſts in winter, but riſeth generally of the ſeede that is ſuffred to ſhed it ſelfe.

The Place.

This came as it is thought from ſome part of *Braſſile*, and is more familiar to our countrey then the other *Indian* ſorts, early giving ripe ſeede when as the others ſeldome doe.

The Time.

It flowreth from *Iune* ſometimes unto the end of *Auguſt* or later, and the ſeede ripeneth in the meane time.

The Names.

The name *Petum* whereby it is called, is properly from *Braſſil*, as I am given to underſtand, and yet ſome have affirmed that this herbe is not the right herbe, the *Indians* there ſo called, wee received it by that name which is ſo continued. It is thought alſo by ſome that *Iohn Nicot* the French man, being agent in *Portugall* for the *French* King, ſent this ſort of Tabacco and not any other to the *French* Queene, and is called thereupon *herba Regina*, and from himſelfe *Nicotiana*, which is probable becauſe the *Portugalls* and not the *Spaniardi* were maſters of *Braſile*

at that time: the *Indian* names of *Picielt* and *Perebecenne* are more proper as I take it to the other *Indian* kinds: wee doe usually call it in *England* Englisch Tobacco (not that it is naturall of *England* but) because it is more commonly growing in every countrey garden almost, and better endureth then the other: *Lobel* and others accounted it, as well as the other sorts an *Hyoscyamus*, and called it *Hyoscyamus luteus*, and *dubius*, and thereupon some have called it in *Englisch* yellow Henbane.

The Vertues.

This kind of Tabacco although it be not thought so strong, or sweete for such as take it by the pipe, (and yet I have knowne Sr. *Walter Raleigh*, when he was prisoner in the Tower, make choise of this sort to make good Tobacco of, which he knew so rightly to cure as they call it, that it was held almost as good as that which came from the *Indies*, and fully as good as any other made in *England*:) nor yet so effectuall for inward diseases, because it is not so much used as the other, yet it is availeable by good experience for to expecterate tough flegme out of the stomacke, chest and lungs, that doth offend them: the juice thereof being made into a Syrupe, or the distilled water of the herbe drunke with some Sugar, or without as one will, or else the smoake taken by a pipe as is usuall, but fasting. The same also helpeth to expell wormes in the stomacke and belly, as also to apply a leafe to the belly, and to ease the paines of the head, or the Megrime, and the griping paines in the bowells, although to some it may seeme, to bring or cause more trouble in the stomacke and bowells for a time: it is also profitable for those that are troubled with the stone in the kidneyes, both to ease paines, and by provoking urine to expell gravell and the stone engendred therein, of that viscous matter, and to heale the parts; and hath beene found very effectuall to suppresse the malignitie and expell the windy and other offensive matters, which cause the strangling of the mother: the seede hereof is much more effectuall to ease the paines of the toothach, then any Henbane seede, and the ashes of the burnt herbe to clense the gummes and teeth and make them white: it hath beene thought not to have beene safe for weake bodies and constitutions, nor for old men, but of both sorts I have seene the experience that it hath bin profitable being taken in a due manner, that is fasting, and to bedward and before meate. *Thevet* saith that the Women in *America* forbeare the taking of Tobacco, because that they have beene taught that it will hinder conception and bodily lust: the herbe bruised and applyed to the place of the Kings Evill, helpeth it in nine or ten dayes effectually: it is said also to bee effectuall to cure the dropsie, by taking foure or five ounces of the juice fasting, which will strongly purge the body both upwards and downewards. *Monardus* saith it is an *Alexipharmacum* or Counterpoison, for the biting of any venemous creature, and to apply the herbe also outwardly to the hurt place. The distilled water is often given with some Sugar before the fit of an Ague, both to lessen the fits and to alter them and take them quite away in three or foure times using; which water above many other will taste of the sharpenesse of the herbe it selfe, but will yeeld no oyle or unctuous substance, as most other herbes will doe, although divers have boasted to make an oyle thereof; if the distilled *faces* of the herbe having beene bruised before the distillation, and not distilled dry bee set in *fimo calido*, to digest for 14. dayes, and afterwards hung up in a bagge in a wine Sellar, that liquor that distilleth therefrom is singular good to use for Cramps, Aches, the Gout and Sciatica, and to heale itches, scabbes and running Vlcers, Cankers, and foule sores whatsoever: the juice also is good for all the said greefes, and likewise to kill lice in childrens heads: the greene herbe bruised and applyed to any greene wound is commonly knowne to country folkes, to cure any fresh wound or cut whatsoever: and the juice put into old sores both clenseth and healeth them, for which purpose many doe make a singular good salve hereof in this manner. Take of the greene herbe three or foure handfulls, bruise it and put it into a quart of good oyle of Olives, boile them on a gentle fire untill the herbe grow dry and the oyle will bubble no longer, then streine it forth hard and set it on the fire againe, adding thereto Wax, Rosen and Sheepes Tallow, or Deares Suet which you will, of each a quarter of a pound, of Turpentine two ounces, which being melted put it up for your use: Some will adde hereunto of the powder of *Aristolochia rotunda*, round Birthwort, and of *Olibanum* that is, white Frankinsence of each halfe an ounce, or six drams, which are to bee put in when it is nigh cold, and well stirred together: this salve likewise will helpe impostumes, hard tumors, and other swellings by blowes or falls.

Tabacco Anguicum. Englisch Tabacco.

CHAP. CX.

Pedicularis ſive Fiſtularia. Rattle graſſe.

OF the Rattle graſſe there are two eſpeciall kinds, the one with red flowers, the other with yellow, and of each ſeverall ſorts as ſhall be ſhewed.

1. *Pedicularis pratenſis rubra vulgaris.* Common red Rattle.

This hath ſundry reddiſh hollow ſtalkes and ſometimes greene riſing from the roote, lying for the moſt part on the ground, yet ſome growing more upright with many ſmall reddiſh or greeniſh leaves ſet on both ſides of a middle rib, finely dented about the edges: the flowers ſtand at the toppes of the ſtalkes and branches of a fine purpliſh red colour, like ſmall gaping hoods after which come flat blackiſh ſeede in ſmall husks which lying looſe therein will Rattle with ſhaking: the roote conſiſteth of two or three ſmall whitiſh ſtrings, with ſome fibres thereat.

2. *Pedicularis major Alpina.* The greater mountaine Rattle graſſe.

This riſeth up neare halfe a yard high with a thicke creſted ſtalke ſet ſomewhat thicke, with long ſtalkes of winged leaves made after the manner of Ferne, notched about the edges one above another, the flowers are like the former but of a whitiſh colour growing in a long ſpike, after which doth follow broader huskes conteining flat ſeede therein like unto Madwort: the root is long, thicke and blacke.

3. *Pedicularis minor Alpina.* The leſſer mountaine red Rattle.

This ſmaller ſort groweth much lower then the laſt, and with fewer leaves on the ſtalkes, which are ſlender alſo but hollow like unto them: the flowers likewiſe are ſmaller and ſet on a ſhorter ſpike, but of a brave ſhining red colour: the huskes that follow are greater then the firſt, with long beakes at their ends, having cornered ſeede within them: the roote is long and white of the bigneſſe of ones finger, with ſome great fibres thereat.

4. *Pedicularis ſive Criſta galli lutea.* Yellow Rattle, or Coxcombe.

The common yellow Rattle hath ſeldome above one round greene ſtalke riſing from the roote about halfe a yard or two foote high, and with but few branches thereon, having two long and ſomewhat broad leaves at ſet a joynt deepely dented or cut in on the edges, reſembling therein the creſts or combe of a Cocke, broadeſt next to the ſtalke and ſmaller to the end: the flowers grow at the toppes of the ſtalkes with ſome ſhorter leaves with them, being hoodded after the ſame manner that the others are, but of a faire yellow colour in moſt, or elſe in ſome paler and in ſome more white: the ſeede is conteined in large huskes, and being ripe will rattle or make a noyſe with lying looſe in them: the roote is ſmall and ſlender periſhing every yeare.

5. *Pedicularis Alpina lutea.* Mountaine Yellow Rattle.

The ſtalke hereof groweth halfe a yard high, ſet with long winged leaves, compoſed of many ſmall finely

1. *Pedicularis pretenſis rubra vulgaris.* Common red Rattle.

4. *Pedicularis ſive Criſta Galli lutea.* Yellow Rattle, or Coxcombe.

dented leaves up to the toppes of them, where they are bare of leaves and beare long ſpikes of gaping and hooded yellow flowers, which yeeld afterwards ſmall long huskes like thoſe of Snapdragon with ſmall ſeede in them: the roote is made of divers long blackiſh fibrous ſtrings.

6. *Criſta galli lutea umbellata.* Yellow Rattle with flowers in tufts.

This hath but few and narrrow leaves of an inch long a peece, riſing from a ſlender ſmall roote and a ſtalke from among them little more then an handbreadth high, having many yellow flowers ſet together at the toppe as it were in an umbell or tuft, faſhioned like the other, but three times longer then thoſe of the common ſort, and with great broad huskes conteining the ſeede after them.

7. *Criſta Galli anguſtifolia montana.* Mountaine narrow leafed yellow Rattle.

This yellow Rattle hath two long and narrow pointed greene leaves dented about the edges, ſet one againſt another upon the ſtalke, which is a cubit high, from betweene which riſe other ſmaller leaves and a ſmall ſtalke likewiſe an inch or two long, with very ſmall leaves thereon, and ſmall pale yellow flowers like the ordinary ſort but ſmaller, with flat ſeede in ſmall huskes following them.

The Place and Time.

Some of both theſe kinds grow in our medowes and woods generally through the land, where they are rather a plague or annoyance to it, then of any good uſe for the cattle, but the reſt in *Germany* except the ſixt which is of *Spaine*; and are in flower from Midſomer untill *Auguſt* be paſt ſometimes.

The Names.

The later writers (for none of the ancients have remembred any of them as farre as can bee underſtood) call them *Pedicularis* and *Pedicularia*, becauſe that ſheepe feeding thereon will breede lice, it is called alſo *Fiſtularia* of the hollowneſſe of the ſtalkes and *Criſta Galli* or *Gallinacea*, becauſe the flowers as ſome thinke ſtand like a Cockes Combe at the toppes of the ſtalkes: others thinke it to be ſo called of the leaves eſpecially, of the yellow whoſe dentings on the edges reſemble the Combe or creſt of a Cocke: ſome alſo call them *Alectorolophus* of *Pliny*, whoſe deſcription commeth neareſt unto this, above any other herbe that is knowne: ſome alſo referre it to the *Mimmulus herba* of *Pliny*, *lib.* 18. *cap.* 28. which as he ſaith is the worſt herbe in a field, but ſome thinke the word of *Pliny* ſhould rather be *Nummulus* for *Nummularia*. The firſt is called by all theſe names by the ſundry authors that have written thereof, and *Lugdunenſis* beſides calleth it *Criſta galli altera ſive Phthirion*: the ſecond is called by *Lugdunenſis* as I doe in the title *Pedicularis major Alpina*, and *Bauhinus Pedicularis Alpina Filicis folio major* as he doth the third *Filicis folio minor*, and is the *Alectorolophus minor* of *Cluſius*: the fourth is called *Pedicularis pratenſis lutea vel Criſta Galli* by *Bauhinus*; and *Campeſtris* by *Tragus* or *Criſta galli* or *Gallinacea* by *Dodonæus*, *Lobel*, *Cluſius*, *&c.* the fift is called by *Lugdunenſis Filipendula Alpina*, and *Pedicularis Alpina lutea* by *Bauhinus*: the ſixt and laſt are mentioned onely by *Bauhinus* with the ſame names are in their titles. The *French* call it *Creſte decoc*, the *Germans Brawn rodel* and *goel nodel*, and ſome *Leuſſkraut*, the *Dutch Ratelen*, and we in *Engliſh* red or yellow Rattle, and Rattle graſſe, Cockes combe and Louſewort.

The Vertues.

The red Rattle is accounted profitable to heale up Fiſtulaes and hollow Vlcers, and to ſtay the flux of humours to them, and alſo the abundance of womens courſes, or any other flux of blood, to be boiled in harſh or red wine and drunke. The yellow Rattle or Cocks Combe is likewiſe held to bee good for thoſe that are troubled with a cough or with dimneſſe of ſight, if the herbe being boiled with beanes and ſome honey put thereto bee drauke or dropped into the eyes: the whole ſeede being put into the eyes doth draw forth any skinne, filme or dimneſſe from the ſight without trouble or paine. Some hold it to be of a cold and drying propertie.

CHAP. CXI.

Balſamina mas. The Male Balſame Apple.

HAve in my former booke given you the knowledge of the female Balſame, it reſteth in this to ſhew you the male, which for the excellent healing properties of this as well as the other, deſervedly have received the name of a Balſame, and therefore I thinke it not amiſſe to give you the figure alſo of the female and male altogether: the male may either be reckoned among the climers for the manner of the growing, or for a kind of Cowcumber as ſome authors doe, for the forme of the flowers and fruite. It ſpringeth up with divers ſlender reddiſh ſtalkes and branches, ſhooting forth many claſping tendrells like a Vine, whereby it taketh hold of any poale or other thing that ſtandeth neare it (yet had neede of ſome binding thereto leaſt the winds blow it downe) having leaves thereon cut in on the edges into ſundry diviſions, like unto a Vine leafe, or the white Bryony, but much ſmaller, tenderer and more divided: the flowers are yellowiſh white, like unto thoſe of Cowcumber, cumming forth in the ſame manner, at the joints with the leaves; after which come the fruite which is ſomewhat long and round, pointed at both ends, and bunched forth on the outſide in rowes, the skin it ſelfe being ſmooth and very red, almoſt blacke when it is ripe, having a reddiſh pulpe, within which lye divers rough and hard flat reddiſh ſeede, but of a grayiſh blacke colour, being dryed, ſomewhat like unto Citrull ſeedes for the forme and bigneſſe: the rootes are ſmall and ſtringy, periſhing with the firſt cold nights it feeleth, and the whole herbe withereth preſently.

The Place.

Wee have alwayes had the ſeede hereof from *Italy*, where alſo they nurſe it up in their gardens, the naturall place of the growing being unknowne to them.

The Time.

It flowreth late with us and ſeldome or never giveth ripe fruit, our cold nights being over early, for it to ripen before it feele them.

The Names.

This never found any Greeke appellation that I can heare of, but is called in Latine *Balſamina mas*, to diſtinguiſh it from the other that is called *famina*, and tooke the name from the *Balſamine* or healing properties are in it,

Balſamina mas. The Male Balſame Apple.

Balſamina fœmina. The female Balſame Apple.

it, yet is thought by ſome to be the plant that *Pliny* in his 20. booke and 3. Chap. ſaith the Grecians called *Cucurbita Somphos*. Some calleth it *Viticella*, from the ſhew of a ſmall vine it beareth; *Cordus* in his hiſtory of Plants calleth it *Cucamis puniceus*, *Geſner Balſamina pomifera*, *Lobel Balſamina Cucumerina punicea*, the *Italians* call it *Balſamina*, and *Caranza* (from whence came the name *Carantia*) and *Momordica* (yet differeth as *Matthiolus* noteth it from the greater kind of *Geranium*, with Mallow like leaves ſo called alſo, whereof is ſpoken before) and ſome *Pomo di Hieroſolima*, *Pomum Hieroſolymitanum*, the *French Merveille* & *Pome de Merveilles*, *Pomum Mirabile*, the *Germans Balſamopfel*, and *Balſamkraut*, the *Dutch Balſame appel*, and we in *Engliſh* the Male Balſame Apple, and of ſome Apples of *Hieruſalem*.

The Vertues.

The Balſame Apple is dry in the ſecond degree, and temperately cold, a decoction of the leaves in wine, or the powder being drunke is ſayd to eaſe the griping paines of the bowells, and the collicke paſſion, as alſo of the mother if it be injected with a Syringe for the purpoſe: the powder of the leaves taken in the diſtilled water of Horſetaile or Plantane, is a ſingular remedy for the Rupture or burſting in children: the chiefeſt manner of uſing it in *Italy*, is to make an oyle of the fruit thereof, when it is ripe by infuſing the Apples, the ſeede being firſt taken forth (and yet ſome make an oyle out of the inner kernell of the ſeede, by expreſſion, in the ſame manner that oyle is expreſſed from Almonds) in oyle Ollive and ſet in the Sunne for certaine dayes, or digeſted in *Balneo*, or *Fimo Equino* which is effectuall not onely for inward wounds or hurts whatſoever being drunke, (the powder of the leaves alſo is effectuall) but for all other outward wounds, be they freſh and greene, to ſoder the lips of them and heale them, or old and inveterate Vlcers to dry up the ſuperfluous moiſture, and defluxion of humous hindring their healing, and to heale them quickly: the ſame oyle alſo is very profitable for all prickes or hurts in the ſinewes as alſo for crampes and convulſions, if the places bee therewith annointed, and to heale the Vlcers of the ſecretparts in man or woman, or womens breaſts that are ſore or ſwollen: it helpeth alſo to eaſe the paines of the piles: it cureth alſo ſcaldings or burnings by fire or water: it taketh away the ſcarres that remaine of wounds and hurts being healed, it dothalſo take alway the paines of the ſtingings of Bees and Waſpes: it is ſaid likewiſe to be very profitable for women that are barren by correcting the ſuperfluous humidity of the mother, which migh be the cauſe thereof, and thereby to make them fit to conceive.

CHAP. CXII.

Trifolium odoratum. Sweet Trefoile.

THe name of Balſame mentioned in the laſt Chapter, cauſeth me to joyne this herbe next thereunto, being ſo called alſo of many, and the properties well worthy of that name, whereunto I thinke meete to joyne two or three other Trefoiles thereunto, this being of knowne properties, the other of likely.

I. *Trifolium*

1. *Trifolium odoratum ſive Lotus Urbana.* Sweet Trefoile or Balſame.

The ſweete Trefoile riſeth up with one ſtrong round whitiſh ſtalke, three or foure foote high, ſpreading forth many branches on all ſides, whereabout are ſet many leaves upon long footeſtalkes, three alwayes ſet together, of a whitiſh greene colour, very ſoft, and ſomewhat dented about the edges, of the ſent of *Fenugreck*, which is thought to alter ſeven times a day, and is but a fancy, at the toppes of the branches ſtand many flowers cloſely ſet together, each of them like unto thoſe of *Melilot* but larger, and of a bleake, or pale, watchet, blew colour: after which come round white heads conteining darke yellowiſh coloured ſeede: the roote is ſmall white and threddy, periſhing every yeare, and raiſing it ſelfe from the ſeede that ſheddeth, or being ſowen in the Spring.

2. *Trifolium Aſphaltites ſive bituminoſum.* Strong ſmelling Claver.

This kinde of Trefoile or Claver hath his firſt leaves ſomewhat larger and rounder then thoſe that grow upon the ſtalkes, three alwayes ſtanding together upon a long footeſtalke, of a darke greene colour almoſt ſhining, ſet with ſome hairineſſe thereon: the ſtalke is ſtrong round and hairy alſo, riſing to the height of two foote or better, whereon grow the leaves, more long and pointed then the lower, branching from the bottome moſt uſually to the toppe, where grow many large flowers in a buſh or tuft, thicke ſet together, of a blewiſh purple colour and ſomewhat hairy or hoary withall eſpecially the huskes conteining the flowers, which afterwards turne into hairy browniſh broad cods conteining every one but one ſeede, which is ſomewhat broad, rough and pointed at the one end: the roote periſheth with us every yeare, but abideth in the hotter countries where it is naturall. The ſmell of the leaves and whole plant is ſomewhat ſtrong almoſt like Rue, or Herbegrace, eſpecially while they are young, but much ſtronger when they are growne old, even of *Bitumen* whereof it tooke the name: but although it retaineth his ſent in his naturall and hot places; yet with us I have obſerved the ſtrong ſent waxeth weaker every yeare then other, and after the ſecond yeares ſowing to be almoſt without any ſent at all; ſo much can doe (in this as in many other plants) the temperature and moiſture of our countrey.

3. *Trifolium Bituminoſum Americanum.* Strong ſmelling Claver of *America*.

This other bituminous Claver hath a ſlender, darke red, cubit high ſtalke, branching from the bottome to the toppe; ſet with long leaves which are hairy and clammy, three alwayes together on a long footeſtalke, not ſmelling ſo ſtrong being bruiſed as gently touched, the young ſhoots ſmelling like Rue or Herbegrace, the elder like a Goate or Bitumen: the ends of the branches have purpliſh flowers on them like *Scrophularia*, the great Figwort, with three leaves ſtanding out, and one turned inward, but white within: the greene pods that follow have the like hairy clammineſſe with the leaves, being of a fingers length, and a ſmall purpliſh tippe at the ends, wherein lye Kidney like ſeede: the roote is long and fibrous, whoſe taſte is almoſt as ſharpe as the Anemone: being *annuall* as *Cornutus* ſaith it is to be yearely ſowen (but if it be *Galega Americana flore purpureo* as hee there ſaith ſome called it, and whereby *Robinus* of *Paris* ſent mee a plant long ſince, it dyeth not but abideth many

1. *Trifolium odoratum.* Sweete Trefoile.

2. *Trifolium bituminoſum.* Strong ſmelling Claver.

yeares,

3. *Trifolium bituminosum Americanum.*
Strong smelling Claver of *America.*

4. *Trifolium Americanum.*
Trefoile of *America.*

yeares yet did nēver comē to flowring sincē I had it) In his booke likewise he laboureth sprightly to prove that this plant commeth nearer to the description of *Dioscorides* his *Trifolium Alspaltite*, then that other last described which is accounted the truest with all writers, his greatest reason being grounded from the colour of the flower, which in this received is not purple like the *Hiacinth* which is *Galens* note.

4. *Trifolium Americanum.* Claver of *America.*

This strangē Claver bringeth forth many round stalkes, leaning to the ground, spreading forth into many branches, whereon are set in divers places three leaves upon long footestalkes, each whereof is somewhat round like the *Bituminosum* but larger, of a darke greene colour, more dented about the edges, but of a strong sent, much like thereunto; at the toppes of the stalkes and branches stand long spikie eares of whitish flowers, being somewhat smaller then those of that recited strong smelling Claver, after which come in their places small round and flattish seede: the roote is small and stringy, spreading divers wayes.

The Place.

The first groweth not wilde in *Italy*, *France* or *Germany*, but with them all is onely sowen in their Gardens, and so it is with us; and even *Dioscorides* saith it grew in Gardens in his time, as not growing wilde in *Greece* or other places that he had heard of. The second groweth about *Mompelier* and *Marseilles* as *Pena* and *Lobel* say, and is a stranger at *Venice* and other places of *Italy*, as well as in *Germany* and with us, and onely to be found in the Gardens of those that are curious conservers of rare plants. The two last come from the West *Indies* called *America* as it is thought.

The Time.

The first flowreth in *Iune* and *Iuly*, and doth alwayes perfect his seede, but the others because they flower later, doe often misse to give good seede, whereby we are often to seeke for them againe.

The Names.

The Greeke Λωτὸς seemēth to be taken *a voluptate*, for so *Homer* saith it serveth *Deorum voluptati*. The first is of most of the best writers taken to be the Λωτὸς ἥμερος of *Dioscorides* in Latine *Lotus sativa* or *Urbana*, yet *Matthiolus* taketh it to be his Λωτὸς ἀγρίος, *Lotus sylvestris*, and so doe *Anguillara* and *Castor Durantes*, but *Fuschius*, *Cordus*, *Gesner*, *Camerarius* and *Dodonæus* call it *Lotus sativa*, *Lacuna*, and *Turner Lotus urbana*; *Tragus* calleth it *Trifolium Dioscoridis*, for so *Dioscorides* saith his *Lotus sativa* was called. *Dodonæus* calleth it *Trifolium odoratum alterum*, because he named the *Melilot* in the next Chapter to be *Trifolium odoratum*: *Lobel* calleth it *Lotus hortorum odora*, onely *Tabermontanus* calleth it *Melilotus vera*, *Bauhinus* calleth it *Lotus hortensis odora*, and is the *Melilotus singularis Alpini* by *Pona*, in the description of *Mons Baldus*. Most now a dayes call it *Trifolium odoratum*, and the *Germanes* of old time called it *Siben gezeit* (as *Tragus* and others set it downe) that is seaven times sweete; supposing it lost his sent and gained it againe so many times in a day, which is but a fancy as I said before, but being gathered and kept dry in the house it doth keepe his sent a little, but will smell stronger against rainy weather, whereby many desire to lay it in their chambers, to be as it were their Almanacke to shew them faire

faire and foule weather. It is called of many women now a dayes Balſame for the ſingular healing properties it hath: The other is called by all Authors *Trifolium Aſphaltæum*, or *Aſphaltites* or *Bituminoſum*, *Geſner in hortis Germaniæ* calleth it *Oxytriphyllum*, as *Dioſcorides* ſaith ſome uſed to call it in his time and *Menianthes*: The third is mentioned by *Iacobus Cornutus* in his booke of *Canada* plants. The laſt hath his name in his title, as much as is convenient to know it by: yet *Bauhinus* taketh it to be the *Loti ſylveſtris genus latifolium ex Armenia* that *Cæſalpinus* mentioneth.

The Vertues.

The juice of the ſweete Trefoile as *Dioſcorides* ſaith is uſed with hony to be dropped into the eyes to heple the Vlcers that happen therein, and taketh away all manner of ſpots, as pin or haw, as alſo all skinnes that grow over them to hinder the ſight. *Galen* ſaith it is of a temperate quality, and that it is of a meane vigour in digeſting, ſo it is of a meane propertie betweene heate and dryneſſe. The oyle made of the leaves and flowers hereof, in the ſame manner as I ſayd of the flowers of white Melilot, is ſo ſoveraigne a ſalve (many women calling it a Baulme) for to diſſolve all hard ſwellings, bunches or wennes in any part of the body, as alſo to repreſſe moderately all inflammations, and helpeth to digeſt all corrupt and rotten ſores full of corruption, bringing them to maturitie, and healing them perfectly that it is to be admired: as alſo to heare what properties they ſay it hath, and how wonderfully they extoll it, for all ſorts of greenē wounds as well as old Vlcers, as alſo to eaſe the paines of the Goute: It is ſaid to be good for bruiſes and burſtings of young children, for ſtiffeneſſe and lameneſſe of joynts and ſinewes, crampes, ſtitches, Aches, and generally all other the like outward diſeaſes, whether they proceede of heate or cold. The diſtilled water is good to waſh childrens heads that are broken out with ſcurfe or ſcabbes. They uſe to lay it in Cheſts and Preſſes to keepe Mothes from garments. The ſtrong ſmelling Claver is of a ſtronger and hotter temperature, the decoction thereof made in wine and drunke, eaſeth the paines of the ſides comming by obſtruction, and provoketh Vrine as *Hippocrates* ſaith, it helpeth women who after their delivery are not well purged or cleared of the afterbirth, it provoketh their courſes alſo, and helpeth to expell the birth. *Dioſcorides* ſaith it is very effectuall againſt all venemous creatures, as Serpents or other, and as it is reported ſaith hee, the decoction of the whole plant taketh away all the paines thereof, if the place be waſhed therewith, but if any that hath a ſore ſhall waſh it with that decoction, which hath helped them that have bin bitten or ſtung, it cauſeth the ſame paines in that party, which he had that was ſtung or bitten, and was cured thereby. *Galen* reporteth this matter a little otherwiſe, for hee ſaith that the decoction of the herbe Trefoile that is like unto an Hyacinth, taken in the Spring time when it is freſh, and boiled in water cureth thoſe that are bitten and ſtung by Serpents and other venemous creatures, if the places be waſhed therewith; but if any that are ſound and not bitten ſhall bee waſhed with any of that decoction, (and doth not ſay as *Dioſcorides* thoſe that have a ſore or that are waſhed with the ſame part of the decoction that the other that was bitten was waſhed with) they ſhall feele the ſame paines that he that was bitten felt; and further ſaith, the effect hereof is worthy of admiration that the ſame herbe ſhould cure them that are bitten or ſtung, and cauſe a ſound body or place to be alike evill affected, as if it were ſtung or bitten. *Pliny* alſo in his 21. booke and 21. Chapter ſaith, that he is led to beleeve, that it is venemous to a ſound party to be waſhed therewith, becauſe *Sophocles* the Poet ſaith ſo, and that *Simus* an excellent Phiſition affirmeth that the juice or decoction thereof applyed to one not bitten or ſtung, procureth the ſame paines that he that is bitten or ſtung doth feele, and therefore perſwadeth it not to bee uſed but to thoſe are bitten or ſtung by Serpents, &c. the flowers, leaves or ſeede eyther all together or each ſeverally by it ſelfe being boiled in venegar, and a little hony added thereto being drunke is a ſpeciall remedy for them that are ſtung or bitten by any vinemous creature: the ſeede is of moſt force with *Galen* who appointeth it to be put into Treakles that he cauſed to be made for divers perſons: the ſeede alſo boiled in honied water and drunke is ſingular good for the Pluriſie, provoketh Vrine and allayeth the heate thereof, and is good for the Strangury: it helpeth thoſe that have the falling ſickneſſe, and is ſingular good for women that have the riſing and ſtrangling of the mother, whereby they often ſeeme to be dead: the ſame decoction is alſo good for thoſe that have the Dropſie, and taken before the fit of either *tertian* or *quartaine* Ague, it leſſoneth the fits both of heate and cold, and by often uſing it doth quite take them away: three drammes of the ſeede, or foure of the leaves powthered and given in drinke provoketh womens monethly courſes effectually. The ſecond Claver of *America* by reaſon both of the forme of the leaves, and ſmell ſo neare thereunto may ſeeme to be of the ſame property, but I have not knowne any that have made triall of the effects.

CHAP. CXIII.

Melilotus. Melilot, or Kings Claver.

THe *Lotus Vrbana* mentioned in the laſt Chapter cauſeth mee to joyne the Mellilots next thereunto both for the forme name and nature, being no leſſe effectuall in healing then the other, and unto the more common and knowne ſorts to adde ſome more unknowne to cloſe up this *Claſſis*.

1. *Melilotus vulgaris.* Common Melilot.

This Mellilot which is moſt knowne and growing wilde in many places of this kingdome, hath many greene ſtalkes two or three foote high, riſing from a tough long white roote which dyeth not every yeare, ſet round about at the joynts with ſmall and ſomewhat long, ſtrong, well ſmelling leaves, three alwayes ſet together unevenly dented about the edges: the flowers are yellow and well ſmelling alſo, made like other Trefoiles but ſmall ſtanding in long ſpikes one above another, for an hand breadth long or better, which afterwards turne into long crooked cods wherein is contained flat ſeede ſomewhat browne.

2. *Melilotus flore albo.* White flowred Melilot.

This Mellilot is very like the former, but hath more wooddy ſtalkes riſing up higher, greater, and with ſmallēr greene leaves, ſmelling neare unto the former, but weaker: the flowers likewiſe grow in longer ſpikes and more in number, of a white colour and leſſer alſo, which turne into ſmall round heads and not crooked like the other:

the

the roote is tough whitiſh and ſlender, periſhing uſually after it hath given ſeede but rayſeth it ſelfe againe of the ſhed ſeede, flowring the next yeare after the ſpringing uſually or after the ſeeding.

3. *Melilotus Italica.* *Italian* Melilot.

The *Italian* Melilot hath ſeldome more then one ſtalke riſing from a roote which quickly groweth whitiſh and ſomewhat wooddy, ſet here and there with three leaves at a joynt which are much larger then the former, and the end leafe larger then the other two, ſomewhat unevenly waved or cut in on the edges, of a ſent almoſt as ſtrong as the firſt, yet ſomewhat more pleaſant: at the toppes of the ſtalkes ſtand many flowers ſpike faſhion, but of a more deepe yellow colour, and ſomewhat larger alſo then the firſt which turne into round whitiſh heads greater then the laſt, wherein uſually is but one ſeede conteined: the roote is ſmall long and wooddy, periſhing every yeare, and ſeldome riſeth of the ſhed ſeede, but muſt be new ſowen every ſpring.

4. *Melilotus Syriaca.* *Aſſirian* Melilot.

The *Aſſirian* Melilot riſeth up with divers ſtalkes about two foote high, ſet with joynts, at every one of them three leaves ſomewhat larger then the firſt, but not ſo large as the laſt, and a little dented about the edges: the ſtalkes branch forth toward the toppes, whereon ſtand many pale yellow flowers ſet in order one above another as in the former, which turne into ſmall long and ſomewhat flat cods, a little crooked or bending at the end like an Hawkes bill, wherein the ſeede is conteined: the roote is wooddy and periſheth every yeare after it hath given ſeede: the whole plant as well flowers as leaves and ſeede did ſmell very ſweete at their firſt bringing into Europe, but by degrees grew every yeare weaker, ſo that as it ſeemeth it hath not now neare halfe ſo good a ſmell as formerly it had: this kind as *Pena* ſaith is uſed in *Italy* in ſtead of the true Melilot, whereof they have ſmall ſtore growing with them.

5. *Melilotus Ægyptiaca.* *Ægyptian* Melilot.

This ſmall low Melilot riſeth up with many ſlender weake ſtalkes, rather lying or leaning downe to the ground, then ſtanding upright; whereon grow at the ſeverall joynts thereof, two ſmall greene leaves, and from the joynt likewiſe a ſmall long ſtalke, bearing three ſmall greene leaves at the end; the ſtalkes branch forth diverſly, having many ſmall flowers ſtanding at the toppes of them ſpike faſhion like the reſt, and of a deepe yellow colour; after which come ſmall cods a little crooked at the ends, wherein is conteined ſmall round browniſh ſeede, ſmelling ſomewhat like unto Melilot, and of a Stipticke and ſomewhat bitter taſte: the roote is ſmall with ſome fibres ſet thereat.

6. *Melilotus Hiſpanica foliis maculatis.* *Spaniſh* Melilot.

This *Spaniſh* Melilot hath divers ſmall branches little more then a foote high, at the joynts whereof ſtand two ſmall greene leaves, and likewiſe in the boſome thereof a ſmall long footeſtalke, bearing three ſmall darke greene leaves at the end ſomewhat round pointed, and having many white lines like veines running through every one of them: the flowers are ſmall, of a pale yellow colour, ſtanding at the toppes of the branches, like the other but ſmaller, the roote is ſmall and ſtringy: this hath a ſmall ſweete ſent ſomewhat like unto a Melilot, which hath cauſed it to be referred to that tribe or family.

1. 2. *Melilotus vulgaris vel flore albo.*
The common yelloW or white flowred Melilot.

3. *Melilotus Italica.*
Italian Melilot.

7. *Melilotus*

7. *Melilotus Indiæ Orientalis.* East *Indian* Melilot.

The East *Indian* Melilot is a ſmall low plant, ſcarſe riſing above halfe a foote high, with ſmall ſlender browniſh ſtalkes beſet in ſeverall places with very ſmall greene leaves, three alwayes growing together like the reſt, little or nothing dented about the edges: the toppes of the ſtalkes being not branched at all, are furniſhed with many very ſmall flowers, of a deepe yellow colour; after which come ſmall round heads, ſomewhat like unto the *Italian* Melilot, before ſpoken of, wherein is conteined ſmall browniſh blacke ſeede, which hath a ſtrong ſmell of Melilot, which the other ſorts of Melilot have not, the herbe and flowers hereof having but a very ſmall or no ſent thereof; the roote is ſmall and periſheth every yeare, and muſt be new ſowen in the Spring every yeare that you will ſee it.

The Place.

The firſt as I ſaid is found in many places of this Land plentifully, as in the edge of *Suffolke*, and in *Eſſex* in divers places, as alſo in *Huntington* ſhire and in other places more ſparingly, but moſt uſually either in corne fields, or in corners of Medowes, and in worſe places ſometimes. The ſecond groweth not in any place of this Land naturally but is very frequent in *Germany*, and is onely nurſed up in Gardens with us: The third came to us from *Italy*, and by that *Italian* name wee hold it ſtill: The fourth is ſaid by *Pena* and *Lobel* to come firſt from *Aleppo* in *Syria* to *Venice*; where being ſowen it was found to be of an excellent ſmell, as I ſaid before, but degenerated ſucceſſively by degrees: The fift *Proſper Alpinus* ſaith is peculiar onely to *Egypt*, where they uſe no other ſort of Melilot, as not having any others growing with them: The ſixt *Bauhinus* ſaith was found on the Mountaines of *Caſtile* in great plenty. The laſt hath beene ſent us from *Italy*, among divers other ſtange ſeedes by that name, and therefore wee muſt imagine untill it can bee diſproved, that they came from the Eaſterne parts of *Aſia major*, which uſually wee call the Eaſt *Indies*.

4. *Melilotus Syriaca odora.* Sweete *Aſſirian* Melilot.

The Time.

They doe all flower in the Sommer Moneths of *Iune* and *Iuly*, and their ſeede is ripe quickly after.

The Names.

It is called in Greeke μελίλωτος *quaſi Mellita lotus*, a *Lotus* that ſmelleth ſweete like Honey. In Latine anciently it was called *Sertula Campana*, becauſe the flowers growing in the fields of *Campania* were uſed to bee put into Garlands, and *Corona regia*, becauſe the yellow flowers doe crowne the toppes of the ſtalkes. Some alſo have called it *Trifolium odoratum*, but we have another garden Trefoile more properly called by that name, as you heard in the former Chapter. Some alſo call it *Trifolium equinum*, or *Caballinum*, becauſe it is good paſture for horſes, wherein they delight and thrive well with it; in *Engliſh* wee call it generally Kings Claver as the chiefeſt of all other three leafed graſſes, generally called Clavers or Claver graſſes, and Melilot after the Latine name to be the more eaſily underſtood, yet in ſome places they call it Harts Claver, becauſe if it grow where Stagges and Deere reſort, they will greedily feede thereon. And in ſome places of *Eſſex* they call it Hartwort, becauſe as they thinke the ſeede thereof happening into their bread cauſed paines in the ſtomacke and cheſt, which they uſually call the Heart burne or paines of the heart. The firſt is called by moſt Authors *Melilotus* after the Greeke name; the old Latine name of *Serta* or *Sertula Campana*, being quite left; *Tragus* calleth it *Melilotus major vulgaris*. *Camerarius*, *Dodonæus* and *Lobel* call it *Melilotus Germanica*, and *Thalius* & *Dodonæus Trifoliũ odoratũ*. *Matthiolus*, *Durantes* and *Lugdunenſis* call it *Lotus urbana* and *ſativa*, *Fuſchius* and *Lonicerus Saxifraga Lutea* and *altera*. The ſecond is ſcarſe mentioned but under the other, and is called by *Tragus Melilotus major candida*, and of *Dalechampius Lotus ſylveſtris flore albo*. The third *Camerarius* calleth *Italica*, and *Bauhinus Melilotus Italica folliculis ſubrotundis*. The fourth is called by *Tragus tertia ſpecies Meliloti vulgaris*, who ſaith it is moſt likely to be *Serapio* his Melilot: *Fuſchius*, *Geſner*, *Dodonæus* and *Matthiolus*, make it to be *Melilotus Italica*, but we have another more true *ſpecies*, called *Melilotus Italica* here ſet downe the next before this: and *Lobel* as you heard before called it *Melilotus Syriaca odora*, and that becauſe it came from *Aleppo* as hee ſaith it was much uſed in *Italy* for the true Melilot, and therefore called *Melilotus Italica*. *Bauhinus* calleth it *corniculis reflexis major*. The fift *Proſper Alpinus* ſaith is called in *Egypt Alchimelech*, and is the onely Melilot they uſe. *Bauhinus* calleth it *Corniculis reflexis minor*. The ſixt *Bauhinus* onely giveth the name, being brought to him out of *Spaine*. The laſt hath his name in his title as it hath beene ſent to us; which as I ſaid doth ſtill continue. There hath beene ſome controverſie among our later writers, what herbe ſhould be the true *Melilotus* of *Dioſcorides*, ſome taking a kind of *Cityſus* to be it, others a *Medica* or *Lagopus*, and others a kind of wild *Lotus* without ſent, and ſome alſo doubting of his Melilot, holding it rather to be *Dioſcorides* his *Lotus urbana*: for as *Dodonæus* ſaith, all the Apothecaries in *Germany* were wont to uſe no other Melilot then the *Trifolium odoratum*, but time by degrees hath worne out all theſe opinions, and ſetled a more conſtant of this, and is ſo now generally accepted; for in

forme

former times almoſt every country had a ſeverall Trefoile with yellow flowers to be their *Mellilot*. The *Arabians* call it *Alchilelmelich*, and the *Italians*, *Spaniards*, and *French Melilote*, the *Germanes Edlerſteinklee*, the *Dutch Groote Steenclayeren*, and *Ghemayne Melilot*; and in *Engliſh* as I have ſaid before.

The Vertues.

Dioſcorides ſaith, it hath an aſtringent or binding qualitie. It mollifieth all hard tumours and inflammations, that happen in the eyes or other parts of the body, as the ſeate or fundament, and the privie parts of man or woman, being boyled in wine and laide to the place, and ſometimes the yoalke of a roaſted egge, or the powder of Fenigreeke or Linſeede, or fine flower, or Poppie ſeede, or Endive is added unto it. It healeth thoſe impoſtumes that are freſh, being applied with *terra ſigillata* and wine, and the ſpreading ulcers alſo in the head, being waſhed with a lye made thereof. It eaſeth the paines of the ſtomacke, applied either freſh, or boyled with any other of the aforenamed things. It helpeth alſo the paines of the eares being dropped into them, and ſteeped in Vinegar or Roſewater it mitigateth the headach: Thus ſaith *Dioſcorides*. *Galen* ſaith in his ſixth Booke of ſimple Medecines, that Melilot is of a mixt qualitie, for it hath a little aſtringent facultie in it, and yet it doth digeſt: for the warming or hot qualitie is more abundant therein then the cold. The *Arabian* Phyſitians doe appoint the cods and ſeede, to be uſed in medicines, and make no mention of flowers. The *Greekes* contrariwiſe doe will the flowers onely to be uſed, and never make uſe of ſeede or codds; and therefore as *Matthiolus* ſaith, it is no wonder that the compound plaiſter of Mellilot, which the Apothecaries make, not having any of the meale of the ſeede of the true Melilot therein, doth not worke that effect that the Phyſitians doe expect, for this compound plaiſter is appointed to be uſed, to diſſolve hardneſſe, windineſſe, tumours and ſwellings, both of the ſpleene, liver and belly, as alſo mightily to eaſe the paine of them all, and to heale the *Hypochondria*, or fore part of the belly, about the ſhort ribbes, when it is ſtretched or crackt by the ſwelling thereof; but there is another plaiſter called Mellilot, which is much uſed, to draw and heale all ſores and wounds that neede cleanſing, and is made of the juice of the greene young Mellilot, boyled with Roſen, Waxe, Sheepe tallow, and ſome Turpentine, which if it be well made, will be almoſt as greene as the herbe it ſelfe, and ſmell very ſtrong thereof, although it be two or three yeares old. The flowers of Mellilot and Camomill are much uſed to be put together into glyſters that are given to expell winde, & to eaſe paines, as alſo into pultoſes that are made for the ſame purpoſe, and to aſſwage ſwellings or tumors that happen either in the ſpleene or other parts, by the mollifying or diſcuſſing qualities that are in it: It helpeth alſo inflammations whether in the eyes or face, or other parts of the body. The juyce dropped into the eyes is a ſingular good medicine to take away any filme or skinne from them, that groweth as a cloud to dimme the eyeſight. It is effectuall to be applied to thoſe that have ſodainely loſt their ſenſes by any paroxiſme, as alſo to ſtrengthen the memorie, to comfort the head and braines, and to preſerve them from paines, and the feare of the Apoplexie, if the head be often waſhed, with the diſtilled water of the herbe and flowers, or a lye made therewith. The water alſo diſtilled ſerveth as a perfume, to waſh courſe gloves or other things. The flowers and herbe of the white flowred Mellilot, ſteeped in oyle Olive, and ſet into the Sunne to digeſt for ſome time, and after being boyled in a Balneo of hot water, and ſtrained forth, and other freſh flowers and herbes being put thereto, and Sunned, as before and ſtrained, and ſo uſed at the ſecond or third time, is accounted a moſt ſoveraine Balme, both for greene wounds and old ſores, for ſwellings, inflammations, crampes, convulſions, paines, or aches whatſoever in any part of the body, whether it be in any fleſhy or muſculous part, or among the ſinewes and veines. The *Italian* Melilot, is as effectuall as any of the other, and by ſome accounted to be of more efficacie and vertue. The *Egyptian* Melilot, as *Alpinus* ſaith, the ſeede thereof onely is uſed by them, being boyled, and the places greeved, fomented and bathed with the warme decoction againſt paines of the ſides, the Pleuriſie and *Peripneumonia*, as alſo the paines of the collicke and winde in the belly, the windineſſe or ſtrangling of the mother, or any griefes thereof to ſit in the decoction thereof; and if Fenegreeke and Lineſeede, and Camomill flowers be added thereto, it helpeth all tumors or hard ſwellings thereof, and doth helpe to provoke the monethly courſes, and to open the obſtructions of the veines, and afterwarwards to ſtrengthen the parts. The *Indian* Mellilot, if wee would uſe the ſeede, which as I ſaid before ſmelleth ſtronger than the reſt of the plant, hath no doubt the ſame qualitie that the former have, the ſmell and taſte perſwading plainely thereunto.

Divers other herbes there are that might be referred to this Claſſis, ſome whereof are ſet forth in my former Booke, and ſome you ſhall finde ſpecified as well in the precedent as ſubſequent Chapters of this Worke, which you may obſerve in the Vertues as you reade them.

PLANTÆ REFRIGERANTES ET INTVBACEÆ.
COOLING AND SVCCORY LIKE HERBES.
CLASSIS SEXTA, *THE SIXT TRIBE.*

CHAP. I.

Portulaca. Purſlane.

VNTO the cooling Herbes let me, I pray adjoyne the *Intubaceæ* or *Cichoreacia* whereunto they may more fitly in my minde be added, then to any other, not withſtanding the bitterneſſe in ſome that argues ſome heate.

I have ſet forth the Garden Purſlane in my former Worke, there remaine ſomē other to be ſpoken of here, and firſt of the wilde Purſlane.

1. *Portulaca ſylveſtris.* Wilde Purſlane.

The Wilde Purſlane ſpreadeth upon the ground ſappie reddiſh ſtalkes ſet with thicke fat ſhining greene leaves like in all things unto the garden kinde but ſmaller at the joynts, with the leaves toward the end of the branches, come forth very ſmall ſtarre-like yellowiſh greene flowers ſcarſe to be diſcerned, and as quickly falling away as the Garden kinde, and hath ſuch like hard huskes wherein the like blacke ſeede is contained: the rootes are threedes, and periſh with the firſt cold nights that come: this is ſomewhat more aſtringent in taſte (as for the moſt part all wilde herbes are) then the Garden kinde.

2. *Portulaca exigua Camerarij. Camerarius* his ſmall Purſlane.

This ſmall Purſlane alſo is like the other, but much ſmaller then it, having alwayes two leaves ſet together, of a paler yellowiſh greene colour on the thicke round ſtalkes and branches which ſtand a little more upright and bend downe to the ground againe: the flowers are like the former, and ſo is the blacke ſeede, but the huskes open themſelves before the ſeede is ripe, and ſtand upon ſmaller and longer footeſtalkes, this hath little or no taſte but wateriſh or herby.

3. *Portulaca Cretica.* Candy Purſlane.

The *Candy* Purſlane (which in my judgement might rather be referred to the kindred of the ſmall Houſeleekes, as *Camerarius*, *Columna* and *Bauhinus* doe, but that I would keepe the name whereby it was ſent, for his ſake that ſent it) is a very ſmall low berbe not paſt two or three inches high, having many ſmall heads of leaves ſtanding round together, ſomewhat like the head of a ſmall Houſeleeke, but each leafe ſet further in ſunder and not cloſing which are very ſmall at the bottome, and ſodainely grow broad and round at the point, yet ſo ſmall as no leafe is bigger than the naile of ones little finger, and of a pale greene colour, which ſo abide for the moſt part the firſt Winter after the ſpringing up, if the extremitie thereof doe not utterly rot it: in the Sommer following it ſhooteth forth into branches with ſomewhat longer leaves on them, and at the upper joynts and toppes ſtand divers ſmall whitiſh flowers, and after them appeare long pods a little crooked or bending upwards ſet together in forme of a ſtarre, wherein is very ſmall blackiſh ſeede contained; the roote is ſmall and fibrous, and periſheth after ſeede time.

The Place.

The firſt groweth in Vineyards, Orchards, Gardens, and other rockie and ſtony places alſo where it is ſo apt to abide from it owne ſowing, that it will hardly be rid out againe: the ſecond *Camerarius* ſaith *in horto Medico*, that he firſt before any other found it about *Lipſwicke*: the laſt was ſent me from *Hieronymus Winghe*, a Canon of *Tournay* in *Flanders*, who it is likely, either received it himſelfe or ſome other friend that gave it him from *Candy*.

The Time.

The two firſt doe abide all the Summer, from the Spring that they riſe, which yet is late, untill the cold nights doe nippe them, and cauſe them to periſh: the third, as I ſaid before, abideth the firſt Winter of it be not too violent, and ſeedeth the next Summer after the ſpringing.

The

2. *Portulaca ſativa & ſylveſtris.*
Garden and wilde Purſlane.

3. *Portulaca Cretica.*
Purſlane of *Candy.*

The Names.

It is called by *Dioſcorides* in Greeke ἀνδράχνη *Andrachne*, and by *Theophraſtus* ἀδράχνη *Adrachne*, and ſo each of them alſo call the *Arbutus* or Strawberry tree, which ſome call *Portulaca arbor* in Latine, as they alſo call this herbe *Portulaca herba*, of the *Arabians Bakle ancha*, and *Bachele alhanica*, the *Italians Porcellana* and *Porchacchia*, the *Spaniards Verdolagas* and *Baldroegas*, the *French Pourpier Porchailles* and *Porcellaine*, the *Germanes Burgel*, *Burtzel*, & *Portſelknaut*, and *Grenzel*; the *Dutch Porceleyne*, and we in *Engliſh Purſlaine*: The firſt is generally called *Portulaca ſylveſtris*: *Geſner* and *Camerarius* call it *Portulaca minor*: *Cæſalpinus* and *Bauhinus Portulaca angu ſtifolia*; and *Cordus* upon *Dioſcorides* ſaith that *Cepæa* is no other than the wilde Purſlane: the ſecond is called by *Camerarius Portulaca exigua*, and by *Bauhinus Portulaca arvenſis*: the laſt was ſent me by the name of *Portulaca Cretica*, which as I ſaid I am not willing to alter, although I know that *Camerarius* hath ſet it forth by the name of *Aizoon peregrinum*, and *Columna* by the name of *Sempervivum tertium Dioſcoridis*, refuſing that of others ſo accounted, and *Bauhinus* doth thereupon call it *Cotyledon ſtellata*.

The Vertues.

Garden Purſlane is cold in the third degree, and moiſt in the ſecond as *Galen* ſaith, & is therefore good to coole any heate in the liver, bloud, reines and ſtomack, and in hot agues nothing better: it ſtaieth alſo hot and collericke fluxes of the belly, as alſo of womens courſes, the whites & *gonorrhœa*, the diſtillations from the head & the paines therein proceeding of heate, want of ſleepe, or the frenzie: the ſeede is more effectuall then the herbe, and is of ſingular good uſe to coole the heate and ſharpeneſſe of urine, and the outragious luſt of the body, venereous dreames and the like, in ſo much that the over frequent uſe thereof extinguſheth the heate and vertue of natu rall procreation: the ſeede being bruiſed and boiled in wine, and given to children that have the wormes expelleth them; ſome doe more commend the ſeede of wilde Purſlane for the wormes then the other: the juice of the herbe is held as effectuall for all the purpoſes aforeſaid, as alſo to ſtay vomitings and taken with ſome Sugar or Hony helpeth an old and drie cough, ſhortneſſe of breath and the tiſicke, and to ſtay an immoderate thirſt taken upon extreame heate. The diſtilled water of the herbe is uſed by many as the more pleaſing to the palate taken with a little Suger and worketh to the ſame effect. The juyce alſo is ſingular good in the inflammations and ulcers of the ſecret parts in man or woman, as alſo of the bowells and *hemorrhoides* when there are ulcers or excorriations in them. The herbe is ſufficiently knowne to be uſed in ſallets in the heate of the yeare, to coole and temper the bloud and hot and fainting ſtomackes, and is good for them to uſe that have the falling ſickneſſe: the herbe bruiſed and applied to the forehead and temples, allaieth exceſſive heate therein cauſing want of reſt and ſleepe; and applied to the eyes taketh away the redneſſe and inflammations in them, and thoſe other parts where puſhes, wheales, pimples, Saint *Anthonies* fire, and the like, breake forth, eſpecially if a little Vineger be put to it, and being laid to the necke with as much of Galles & Linſeede together taketh away the paines therein, and the cricke in the necke: the juyce alſo is uſed with oyle of Roſes for the ſaid cauſes, or for blaſtings by lightening, or planets, and for burnings by Gunpowder, or other wiſe, as alſo for womens ſore breaſts, upon

the like hot cauſes,and to allay the heate in all other ſores or hurts:it is ſaid alſo to ſtay the ſpreading of venemous ſerpents bitings, and to draw forth the poyſon;applyed alſo to the Navell of children that ſticke forth it helpeth them, it is alſo good for ſore mouthes and for ſore gums when they are ſwollen,to faſten looſe teeth, and to take away their paine when they are ſet on edge by eating ſower things : *Camerarius* ſaith that the diſtilled water uſed by ſome tooke away the paine of their teeth when all other remedies failed, and that the thickened juice made in pilles with the powder of gum *Tragacanth* and *Arabeck*, and taken prevailed much to helpe thoſe that made a blooddy water : applyed to the Goute it eaſeth the paines thereof,and helpeth the hardneſſe of ſinewes, if it bee not cauſed by the crampe or in a cold cauſe. The wilde Purſlane is uſed as familiarly in ſallets and meates in many parts beyond the Seas where it groweth plentifully, as the Garden kinde, and they finde it no leſſe effectuall a remedy for moſt of the diſeaſes aforeſaid, onely it cooleth not ſo ſtrongly, but is more aſtringent and drying for fluxes and the like.

CHAP. II.

Portulaca marina. Sea Purſlane.

THe Sea Purſlane might bē entrēated of with the other Sea plants in the propēr place, but that I thinke it not meete to ſever it from the other going before, and hereunto for the neare likeneſſe and reſemblance to joyne two other ſorts of *Halimus*, which may be called Sea Purſlanes as well but growing in a hotter climate.

1. *Portulaca marina noſtras.* Sea Purſlane of our countrey.

The Sea Purſlane hath divers hoary and grayiſh purple ſtalkes ſomewhat wooddy, riſing from the roote about a foote or more long,lying for the moſt part upon the ground, bearing thereon many ſmall thicke fat and long leaves of a whitiſh greene colour ſet without order, at ſome joynts more and at ſome leſſe, branching forth here and there,and bearing at the toppes many long ſprigges or ſpiked ſtalkes, ſet round about with greeniſh purple flowers,which turne into whitiſh flat thinne ſeedes like unto thoſe of the Sea *Arrache*, the roote is ſomewhat wooddy, with divers long ſtrings joyned thereto and abideth with the leaves on the branches all the Winter.

2. *Halimus latifolius ſive Portulaca marina incana major.* The greater outlandiſh or hoary Sea Purſlane.

This hoary Sea Purſlane ſendeth forth divers thicke and wooddy hoary & brittle ſtalks, foure or five foot high, whereon are ſet many thicke leaves,without any order ſomewhat ſhort & broad,ſo hoary white that they almoſt gliſter : the flowers grow at the tops of the ſtalkes on divers long ſprigges, being moſſie like the Olive bloſſome, but of a purpliſh colour ; after which come broad and flat whitiſh ſeede like unto thoſe of *Arache* : the roote is long hard and wooddy enduring many yeares in the naturall places, but muſt bee ſomewhat defended in the

Portulaca marina.
Sea Purſlaine.

2 *Halimus latifolius ſive Portulaca marina incana major.*
The greater outlandiſh or hoary ſea Purſlane.

Winter

Winter with us if you will have it preſerved, yet bringeth not forth the leaves ſo hoary white with us.

3. *Halimus tenuifolius ſive Portulaca marina incana minor.* The leſſer outlandiſh or hoary Sea Purſlane.

This other hoary Sea Purſlane hath very ſlender, weake, and ſomewhat hoary ſtalkes about two foote long, ſcarſe able to ſtand upright, but for the moſt part fall downe and lye upon the ground, the leaves that grow on them being ſet in the ſame manner, that is without order, are narrower, longer and not ſo hoary white: the flowers are like the former, but of a more greeniſh colour growing at the toppes of the ſtalkes, and afterwards yeeld ſuch like ſeede as the former, but ſomewhat leſſe: roote is wooddy and endureth like the other.

4. *Halimus minor Germanicus.* The leſſer ſea Purſlane of *Germany*.

This hath a ſmall hoary ſtalke an handfull high, riſing from a ſmall threddy roote leaning divers wayes, branching forth a little above the roote, ſet with ſmall and ſomewhat round leaves, and thoſe up higher with a gaſh on each ſide, of an aſh colour, the flowers are ſmall greeniſh and moſſie, yet yellow within, ſet on long ſtalkes, after which come ſquare huskes with ſmall gray ſeede like unto kidneys in them.

The Place.

The firſt groweth in the ſalt marſhes of the Sea coaſts of our owne land, in *Kent* and many other places: the ſecond *Cluſius* ſaith he found about *Liſhbone* in *Portingall*, and the third as well in the kingdome of *Valentia* in *Spaine* as not farre from *Mompelier* and *Marſelles* in *France*, and in the upland places about *Tholouſe* as *Lugdunenſis* ſaith, if his *Halimus* be this as you ſhall heare by and by, the laſt about *Northuſa* in *Germany*.

The Time.

They flower in *Iuly* and their ſeede is ripe in *Auguſt*.

The Names.

Dioſcorides, *Galen* and *Theophraſtus* call it in Greeke Ἅλιμος *Halimus* with an aſpiration, becauſe it is a ſea plant, and taſteth ſomewhat ſaltiſh, whom *Pliny* followeth and yet ſaith, a certaine herbe uſed to be eaten is ſo called alſo, as though it were differing from *Halimus* which as *Dioſcorides* and *Galen* ſay is uſed to bee eaten. *Solinus* and others call it Ἅλιμος *Alimos* without an aſpiration, and ſay the name was taken from the effect it worketh which is to expell hunger, for ſaith *Solinus*, the people in *Candy* ſay that that day they eate thereof they ſhall not be hungry, if you will beleeve them. Divers herbes have beene taken for *Halimus* by divers writers, as the *Atriplex marina* by divers, the *Liguſtrum* or *Privet* by *Lacuna*, and *Periclymenum rectum*, upright Woodbine by *Tragus*. *Lugdunenſis* ſetteth forth a plant by the name of *Halimus vera Dalechampij*, the true *Halimus* of *Dioſcorides*, and ſaith it better agreeth thereto then thoſe of *Cluſius*, or any other, to whom *Cluſius* ſcarſe giveth credit, in that hee ſaith hee ſheweth the fruit thereof to bee like unto *Ribes*, whom *Bauhinus* followeth, and ſaith that he knew not what plant it ſhould be, but reading the place in *Lugdunenſis* I finde *Cluſius* to be much miſtaken, for in the deſcription thereof he ſetteth downe theſe words *Semen producit latum, candicans, in ſummis ramis copioſum*, which broad white ſeede can no wayes agree with *Ribes*. And for *Lugdunenſis* to make it a different plant from *Cluſius* his ſecond *Halimus* whereunto himſelfe ſaith it is like, I ſee no ſuch great cauſe, more then that it grew in the upland countries, and that his Figure ſheweth the leaves to grow many cluſtering together at a joynt. I have you ſee ſet the *Portulaca marina* with the *Halimus*; for in my judgement it differeth not ſo much from it, neither in forme of leaves or ſeede, which is (with me) a chiefe note of agreement or difference, nor yet in place, but that it may very well be accounted the *Halimus* of our countrey, and other theſe Northerne parts, the climates chiefly making the diſtinction if any be, and hereunto I am the more induced becauſe *Matthiolus* his firſt *Portulaca*, and *Cluſius* his laſt be by them called *Halimus* which *Dodonæus* and *Bauhinus* call *Portulaca marina*. *Lobel* and *Pena* affirme that the diſcription of *Portulaca marina* doth better agree with the *Crithmum* of *Dioſcorides* then the *Fæniculum marinum* doth; firſt for that the leaves of *Crithmum* are ſayd to be white which in Sampire are greene, next they are compared to Garden Purſlane leaves but thicker longer, and broader, which cannot agree to *Sampire* being ſmall long and ſomewhat round, and againe *Crithmum* of *Dioſcorides* is ſaid to be of a cubits height, but Sampire is little above an handbreadth or two high, theſe things conſidered did put ſome doubt in them and ſome others ſince whether our Sampire which is generally ſuppoſed to be the right *Crithmum* of *Dioſcorides* be ſo or no: but hereof I ſhall entreate more hereafter when I ſhall ſpeake of *Sampire* in the Claſſis of Sea Plants, *Ruellius Lib.* 1. *Cap.* 85. taketh that plant to be *Halimus* with which the *French* in divers places make their hedges, and call it *Blanche putain*, but he is therein much deceived, that being *Viburnum*; for I thinke he doth not make the *Viorne* to be it which yet they ſo call alſo: *Matthiolus* ſaith that the *Arabians* call *Halimus Molochia*, and that *Serapio* ſpeaking thereof, ſaith that in *Babylon* it is carried by handfulls and cryed in the ſtreets, but I thinke *Matthiolus* is herein deceived, for it is the true *Molochia* and not this herbe that *Serapio* ſaith they cryed in the ſtreets: the laſt is called *Halimus minor* in his *Pinax* and *Prodromus*. The *Italians* as *Matthiolus* and *Lugdunenſis* ſay call it *Bidone*, and *Cluſius* ſaith the *Spaniards* call it *Mariſma*, and the *Portugalls Salguideiras*, and the *French* eſpecially about *Tholouſe L'herbe du Maſclou*, *ideſt*, *Herba Colica*, the Collicke herbe for the properties ſake: we call it Sea Purſlane, as the *Dutch* doe ſo likewiſe.

The Vertues.

The *Halimus* or *Portulaca marina* (for as their formes ſo their properties are alike) is uſed to be eaten as other Sallet Herbes are in all the places of their growing, for taſting ſomewhat ſaltiſh of the naturall ſoyle, being tranſplanted into other grounds, it much pleaſeth the pallate, having a little aſtringent relliſh withall, whereby it is found as *Galen* ſaith to bee of different qualites, as well temperately hot ſufficient to diſſolve winde in the lower belly and guts, and the paines of the Collicke ſpeedily, by drinking of the decoction of the leaves in wine, or of the juice put into wine and being boyled and eaten with oyle or butter, looſeneth the body, and yet by the aſtringent qualitie doth ſtrengthen the looſe or fluxible parts: the ſame alſo helpeth thoſe that are troubled with Crampes or are burſten inwardly: it cauſeth alſo plenty of milke, not onely to Nurſes for their children, but in Cattle alſo that feede thereon, or to whom it is given: it encreaſeth alſo naturall ſeede: but that which *Dioſcorides* attributeth to the roote is found ſufficient effectuall in the leaves, the roote in theſe dayes being ſeldome uſed that I know.

CHAP. III.

Telephium ſive Craſſula. Orpine.

THere be divers herbes exhibited by divers authors for the true *Telephium* of *Dioſcorides*, ſome great, ſome ſmall, ſome tall ſome low, ſome of one faſhion, and ſome of another, and yet none doth truly anſwer in all things the diſcription thereof; but becauſe all or moſt of them have given the name of *Telephium* to theſe herbes here expreſſed; let mee alſo if they have erred erre with them, and yet I ſhall ſhew you which of them commeth neareſt unto the truth or true *Telephium*.

1. *Telephium ſive Craſſula major Hiſpanica.* The great *Spaniſh* Orpine.

The great *Spaniſh* Orpine hath divers weake round ſappie ſtalkes riſing two foote high, whereon are ſet at diſtances two large and thicke broad leaves, very like unto the common Orpine, but much larger and browner of colour oftentimes, and ſomewhat unevenly dented about the edges: at the toppes of the ſtalkes ſtand tufts of flowers, larger and more ſpread then in the ordinary ſort, which conſiſt of five ſmall whitiſh leaves a peece, after which come ſmall chaffie huskes with ſeede like duſt in them: the rootes are thick, white, and tuberous, bigger and longer then thoſe of the ordinary Orpine which abide all the Winter with the greene leaves on their ſtalkes that have not as yet flowred.

2. *Telephium ſive Craſſula major vulgaris.* Common Orpine.

Common Orpine riſeth up with divers round brittle ſtalkes, thicke ſet with flat and fleſhy leaves without any order, and little or nothing dented about the edges, leſſer then the former, and of a paler greene colour, the flowers grow in leſſer tufts, and are white or whitiſh in all that ever I ſaw, which afterwards beare ſuch like ſeedes as the former: the rootes are divers, thicke, round, white, glandulous or tuberous clogges like the former but leſſer: This proveth ſmaller in divers fields and woods ſides where it is found wilde.

Minus ſylveſtre.

3. *Telephium floribus purpureis.* Purple flowred Orpine.

This Orpine differeth little from the laſt in manner of growing, but that the ſtalkes are more flexible and weake, and the leaves which ſtand without order are more finely dented about the edges, and the tufts of flowers at the toppes of the ſtalkes are of a reddiſh purple colour conſiſting of five ſmall leaves a peece like the former, the roote is alſo tuberous like the laſt for the moſt part.

Minus florepurpureo.

This alſo is found ſmaller in all the parts thereof not otherwiſe differing then in that the ſtalkes with all the leaves utterly periſh every yeare to the roote, which every yeare ſendeth forth new branches.

4. *Telephium minus repens ſive Cepæa Pancij.* Small creeping Orpine.

This ſmall creeping Orpine ſendeth forth divers weake round ſtalkes lying on the ground, and eaſily taking roote againe as they lye, thicke ſet with thicke fat leaves very like unto Purſlane, but ſmaller and ſmaller upwards, of a darke or ruſtie greene colour, from among which riſe bare or naked weake ſtalkes, without any, or with

1. *Telephium ſive Craſſulæ major Hiſpanica.* The great *Spaniſh* Orpine.

2. *Telephium ſive Craſſula major vulgaris.* Common Orpine.

but

3. *Telephium floribus purpureis.*
Purple flowred Orpine.

4. *Telephium minus repens sive Cepæa Panctj.*
Small creeping Orpine.

5. *Telephium legitimum Imperati.* *Imperatus* of *Naples* his true Orpine.

but few leaves thereon, at the toppes thereof ſtand ſmall tufts of purpliſh flowers like the other, the rootes hereof are not tuberous but ſtringie, yet doe endure with the greene leaves on them the greateſt extremitie of Winter although it loſe ſome of the lower leaves of the branches.

5. *Telephium legitimum Imperati.* *Imperatus* of *Naples* his true Orpine.

This ſmall *Telephium* of *Imperatus* ſpreadeth upon the ground, with many ſmall and long trayling branches a foote or more long, whereof thoſe that will not flower that yeare have ſmaller and ſomewhat longer leaves on them, and thicker ſet together, but thoſe that will beare flower are ſet ſparſedly without order to the toppes, and are leſſer in forme, and leſſe thicke and ſappie then any of the other before, and of a ſad blewiſh greene colour: at the toppes of the ſtalkes ſtand thicke cluſters of white flowers of five leaves a peece, and after them ſmall cornered heads containing ſmall browniſh ſeede, the roote is ſmall and long of a fingers length or two with divers branches and ſmall fibres abiding with ſome branches of greene leaves thereon, although thoſe that have flowred and ſeeded doe periſh.

6. *Cepæa Matthioli.* *Matthiolus* his ſmall Orpine.

The ſmall Orpine of *Matthiolus* hath a ſmall weake ſtalke ſcarce a foote long lying almoſt upon the ground parted into ſundry branches, and they againe into other ſmaller ones, ſet with ſmall thicke long leaves without

out any order, and ſomewhat like unto Purſlane: at the toppes of the branches ſtand many ſmall white flowers in tufts, but more thinly or ſparſedly ſet then in the former, conſiſting of five leaves a peece, after which come ſmall heads like unto the Orpines containing ſmall duſtie ſeede, the roote is long and fibrous ſmelling ſomewhat ſweete like the Roſewort roote as *Camerarius* ſaith, and periſhing every yeare, ſo that if it riſe not of the ſhed ſeede (which uſually it doth if it be ſuffered to fall) it muſt bee new ſowne every yeare.

The Place.

The firſt *Cluſius* ſaith hee found as well in *Spaine* as in *Hungary* upon the Alpes: the ſecond of both ſorts, the greater and the leſſer is frequent almoſt in every country of this land, the greater being generally cheriſhed in Gardens, but yet is as I take it the ſame with the leſſer ſort, that groweth as I ſayd in the ſhadowie ſides of fields and woods: the third is often found in divers places of *Germany*, as *Tragus*, *Camerarius*, *Cluſius* and others ſet downe: the fourth was ſent out of *Italy* by *Alphonſus Pancius* a worthy Herbariſt and Phiſition of *Ferrara*: the ſixt came from *Imperatus* of *Naples*, from *Cortuſus* and *Ioſephus de Caſa bona*, of whom *Cluſius* ſaith he received the ſeede: the laſt is chiefely nourſed up in the Gardens of thoſe that are lovers of rare plants, and was firſt communicated from *Padoa*.

The Time.

They doe all flower about *Iuly*, and their ſeede is ripe in *Auguſt*.

The Names.

Theſe herbes are referred to the Τελέφιον *Telephium* of *Dioſcorides* for the forme ſake, and ſo taken by divers writers although none of them are found to have that clenſing faculti̇e that *Dioſcorides* and *Galen* attribute unto their *Telephium*: it tooke the name as it is thought from *Telephus*, the King of *Miſia* whoſe wounds received from *Achilles*, and growne almoſt paſt cure were healed herewith, and from hence the medicines appointed for ſuch purpoſes were called *Telephia*. The firſt is called *Telephium Hiſpanicum* of *Cluſius* and others, and *Craſſula major Hiſpanica* of *Lobel* and others: the ſecond is called *Scrophularia media vel tertia* of *Brunfelſius*, *Fabaria*, *Faba craſſa* and *Faba inverſa* by divers, and ſo alſo by *Lobel a foliorum fabæ ſimilitudine* and *Craſſitudine*, and *Craſſula* or *Craſſula major* by divers alſo, as well as by *Dioſcorides a foliorum craſſitie*. *Cordus* upon *Dioſcorides* calleth it *Acetabulum alterum* and *Columna* taketh it to bee *Cotyledon alterum* of *Dioſcorides*, *Geſner in hortis Germaniæ* taketh it to be *Anacampſeros*, and *Matthiolus*, *Dodonæus*, *Cluſius* and divers others call it *Telephium & vulgare*, becauſe it is moſt common in all theſe parts: the third is called *Scrophularia ſen Portulaca major*; by *Tragus Telephium floribus purpureis* by *Lobel* and others, *Acetabulum alterum purpureũ* by *Fuchſius* in his *Icones*, and is the *Telephium quintum* of *Cluſius*, who thinketh his not to differ from that of *Lobel*, notwithſtanding that the rootes thereof be expreſſed without tubers: *Cæſalpinus* calleth it *Craſſula montana*, and *Columna* refuſing it to be any *Telephium* ſaith it is a *Rapuntium*, and thereupon calleth it *Rapuntium umbellatum*: the fourth is the *Telephium ſextum* of *Cluſius* who taketh it more nearely to reſemble the true *Telephium* then any other, and called by him and *Camerarius* alſo *Cepæa Pancij*, by *Dodonæus*, *Lobel* and others *Telephium minus*, and *repens*, and *ſemper virens*: wee uſually call this in Engliſh French Orpine: the fift is called by *Cluſius Camerarius* and all others that have ſeene or had it *Telephium Imperati*, and *Telephium legitimum Imperati*: the laſt is called *Cepæa* by *Matthiolus* and by ſome *Cepæa marina*, but generally by all that ſince have written of it *Cepæa Matthioli*. The *Italians* call it *Fabagraſſa*, the *French Orpin*, *Feve graſſe*, *Feve eſpaiſſe*, and of ſome *Repriſe* and *Ioubarbe des vignes*, the *Germans*, *Wundkraut*, *Dunpenkraut*, *Fotzwein*, and *Fotzwang*, the *Dutch Schmerwortele* and wee in *Engliſh* Orpine, and of ſome Livelong, becauſe a branch of the greene leaves hung up in any place will keepe the verdure a long time, which made *Tragus* to judge it the *Chryſocome* of *Dioſcorides* or elſe an *Aizoon*.

6. *Cepæa Matthioli.* *Matthiolus* his ſmall Orpine.

The Vertues.

The qualities of our Orpine are as I ſayd before differing from the *Telephium* of *Dioſcorides*, in that they are cooling as Purſlane is, eſpecially the leaves, for the roote is more enclining to heate, and by reaſon of the muccilagineſſe therein it is ſomewhat aſtringent alſo, whereas the true *Telephium* as *Dioſcorides* and *Galen* ſay is ſomewhat hot, and of a clenſing drying qualitie, ſo that uſed with Vinegar it taketh away the Morphew, Lepry, and all other deformities in the skinne, and is good alſo for old foule Vlcers and ſores to clenſe and heale them, thus ſay *Dioſcorides* and *Galen* of their *Telephium*, but divers have thought that the difference in qualitie may happen from the Climate as it doth in *Arum* which in ſome places of *Aſia* and *Cilicia* as *Galen* ſaith is not ſharpe and biting, as it is in theſe places of *Greece*, *Italy* and all Europe, and as it is found alſo in the leſſer Celandine, which as they ſay is ſharpe in ſome places but is not ſo found with us. Orpine is ſeldome uſed in inward Medecines with us, although *Tragus* ſaith from his countrey *Germanes* experience, that the diſtilled water thereof is profitably taken of thoſe, that have any gnawings or excoriations in their ſtomacke or bowells, or have Vlcers in their Lungs or Liver or other inward parts, as alſo in the matrix or mother, and doth helpe all thoſe diſeaſes, being drunke for certaine dayes together, and that it ſtayeth the ſharpeneſſe of humors in the blooddy flux, as alſo ſtayeth

other

other fluxes of bloud in the body or in the wounds: the roote thereof also performeth the same effect. It is used outwardly to coole any heate or inflammation upon any hurt or wound, and easeth the paines of them, as also to heale scaldings or burnings, the juyce thereof beaten with some greene sallet oyle and annointed, the leafe also bruised and laid to any greene wound in the hands or legges, doth heale them quickly, and as it is said, being bound to the throate of them that hath the Quinsie, doth helpe it very much: it helpeth ruptures or burstings, and from thence, as *Tragus* saith, the *Germans* call it *Bruchwarts* and *Knabenkraut*. The leaves are much used to make Garlands about Midsommer with the corne Marigold-flowers put upon strings to hang them up in their houses, upon bushes and May-poles, &c. *Tragus* sheweth a superstitious course in his country, that some use after Midsommer day is past, to hang it up over their chamber doores, or upon the walles, which will be fresh and greene at Christmas, and like the Aloe spring and shoote forth new leaves, with this perswasion, that they that hanged it up, shall feele no disease so long as that abideth greene.

CHAP. IV.

Rhodia sive Rhodia radix. Rosewort.

BEcause this plant is so like unto an Orpine, both in leafe, flower, and manner of growing, I thinke it fit to joyne it next thereunto. It sendeth forth divers stalkes which are upright, thicke round and greene, about a foote thicke set with leaves up to the toppes, and are somewhat long and narrow, like unto those of Orpine, but smaller, yet as fat or thicke, and of the like pale greene colour, dented about the edges: the flowers are many small and yellow, set in a tuft or cluster, but smaller than Orpine, with seede in heads like unto it also: the roote is thicke and tuberous or knobbie at the head, and branched out, rising oftentimes above the ground, whereas it groweth somewhat reddish, and is long downward, with divers fibres annexed unto it, which being a little broken or bruised with it, is fresh, much more than when it is drie smelleth like a Rose, from whence it tooke the name. Some doe account that there is an other sort hereof whose leaves are not dented, and the flowers more purplish than the other.

Rhodia radix. Rosewort.

Allen.

The Place.

It groweth in the North parts of *England*, and no where else wilde in our Land as I can heare of, as upon the mountaines of *Pandle* and *Ingelborough*, oftentimes on the very raggiest places and most dangerous of them scarce accessible and so steepe, that they may soone tumble downe that very warily doe not looke to their footing, from whence hath beene sent me some rootes for my Garden.

The Time.

It flowreth about *July*, and the stalkes and leaves perisheth to the ground springing every yeare anew from the roote, which abideth firme in all extremities of cold.

The Names.

It is called in Greek Ῥοδία ῥίζα, *Rhodia radix*, not from the Iland Rhodes, but from the Rose, as I said, for the sent thereof; it hath no other name with all authors than *Rhodia radix* or *Rosea radix* that I know.

The Vertues.

It is found by good experience to be cold and not hot, as some have taken it to be, and as *Galen* placeth it almost in the third degree of heate: for even as red Roses, so this by the coldnesse is profitable to asswage the headeach, arising from an hot cause, and both *Dioscorides* and *Galen* appoint it for paines in the head, the juyce thereof with a little Rosewater applied to the forehead and temples which *Gerard* vindicateth to his owne invention.

CHAP. V.

Aizoon Sedum sive Sempervivum majus. The greater Houseleeke.

THere are so many sorts of Houseleekes properly and unproperly so called both great and small, with whole or with divided leaves, some cooling and others heating or exulcerating, that without some methodicall division, I can neither expresse them conveniently, nor you apprehend them effectually; which that I may do, I will digest them into five Rankes and orders, that is to say, of all the great ones in this Chapter, and of the smaller ones in the severall Chapters following, which because they are of much varietie, I must intreate of those that grow upon muddie stone walles or houses, and upon drie sandie bankes and places in the next: thirdly, of these that grow upon rockes and mountaines or in stony places, and fourthly, of such as beare divided leaves, and lastly, to accomplish the history of all the sorts of Houseleekes, I should set forth

forth the ſorts of *Cotyledon* or Kidney Worts, but having entreated of many of them in my former Booke, I will here ſhew you the reſt that remaine.

1. *Sedum Majus legitimam.* The true great Houſeleeke.

The true great Houſeleeke groweth great to the forme of a ſhrubbe or woddy plant, of the height of two or three foote or more, ſometimes in the naturall places which are the warme countries, whoſe ſtemme or truncke below is of the bigneſſe of foure fingers, and the other branches of ones thumme, of a grayiſh colour on the outſide ſpotted as it were round about, bnt they are the markes of the old leaves that are fallen, the like whereof may be ſeene in the ſtalke of the Wood Spurge, ſpreading limber ſmaller branches on all ſides, and leaves at the ends of them, ſtanding in a compaſſe like the heades of common houſeleeke but nothing ſo cloſe, every leafe formed ſomewhat like a tongue, ſmall at the bottome and broader toward the end where it is broadeſt, finely dented about the edges, and as it were a little hollow like a Spoone, thicke and full of juice, and of a pale greene colour, from the toppes of ſome of the branches thruſteth forth a long ſtalke divided into many twigges, with ſome few ſmall leaves on them, and at the ends of them divers ſtarrelike flowers, conſiſting of many ſmall leaves of a pale yellowiſh colour, with ſundry ſmall threeds in the middle of them, the greater ſtalke becommeth drie and ſmooth as the heads, with ſmall blacke ſeede in them, grow ripe and utterly periſhing after ſeedetime: but the other heads of greene leaves abide freſh all the yeare, which ſend for the flowers the next yeare after, and may be taken before hand from the maine ſtocke to be planted, and will take roote being put into the ground. *Matthiolus* hath ſet forth the figure hereof in another manner with more ſtore of branches and leaves, but it is the ſame plant growing peradventure in a warmer and more temperate climate.

2. *Sedum majus marinum Anglicum.* Great *Engliſh* ſea Houſeleeke.

This kind of Houſeleeke is like the former whoſe ſtemme is wooddy, but neither ſo high nor with ſo many branches, the leaves alſo, although ſomewhat like unto them, yet not ſo thicke or ſappie, in the reſt not much differing from the former.

3. *Sedum majus vulgare.* Our common great Houſeleeke.

Our common Houſeleeke ſendeth forth on all ſides divers heads of pale greene thicke fat broad leaves pointed at the ends, lying circlewiſe one cloſe unto another upon the ground from the middle of ſome of the heads of leaves, riſeth up a ſtreight ſtalke two foote high, all covered with ſmaller and longer greene leaves than thoſe below, which often drie and fall away before the toppe thereof hath perfited the flowers which grow on long branches bending their ends downewards, with a ſingle leafe at the foote of every one of them, and conſiſt of many leaves ſtarre-faſhion, of a darke reddiſh colour, after which come heads with ſmall blackiſh ſeede in them: the roote is ſmall and ſtringie, creeping all about, and from ſmall ſtrings multiplieth into many heads of leaves round about, taking up thereby a good compaſſe.

4. *Sedum majus alterum flore Atlante.* An other ſmaller Houſeleeke like the common.

This Houſeleeke groweth in like manner as the common doth, with ſuch heads of thicke and pointed leaves compaſſing one another, but they are dented a little about the edges, and are much ſmaller than they, ſtanding

1. *Sedum majus legitimum.*
The true great Houſeleeke.

2. *Sedum majus Marinum Anglicum.*
Great *Engliſh* ſea Houſeleeke.

upon

3. *Sempervivum majus vulgare.*
Our common great houseleeke.

5. *Sedum rubrum tomentosum.*
Netted or woolly Houseleeke.

6. *Sedum majus angustifolium.*
Great narrow leafed Houseleeke.

7. 8. *Vermicularis arboreſcens & fruticoſa altera.*
Tree Houseleeke with small leaves, and Shrubby Prickmidam.

Alterum minus majus dentatis foliis. Alterum flore purpureo odorato.

upon longer ſtalkes that thruſt out from the roote: from the middle of the greateſt and eldeſt head, ſhooteth up a ſtalke ſcarce a foote high, thicke ſet with ſmall leaves like the other, bearing flowers in the ſame manner, but larger, and conſiſting of ſixe leaves, onely of a white colour, after which come ſixe cornered heads, containing ſmall blackiſh ſeede: the roote is ſmall and like the other, yet a little thicker. *Cluſius* maketh mention of another ſort hereof, with leſſer leaves and more dented in on the edges in little elſe differing. There is of this kinde an other alike in all things, ſaving the flowers which are of a brighter red colour than the common ſort.

5. *Sedum rubrum tomentoſum.* Netted or Woolly Houſeleeke.

This rare Houſeleeke in the Autume and Winter hath the hoary or aſh coloured heads of leaves, ſmooth, plaine, and open, like unto the ordinary ſort, but when the Spring commeth on, it groweth overſpread with a number of hoary or woolly threades like unto a net, that it draweth the leaves together, and ſheweth divers formes, as triangles, qua drangles, quinquangles, & ſexangles, the leaves themſelves being ſmaller and longer than the ordinary ſort but thicke and fleſhie: in Summer when the ſtalke riſeth to be halfe a foote high, they grow pointed up Pyramis faſhion, thicke covered with that woollineſſe: upon the ſtalke are ſet many ſmaller and narrower leaves up to the toppe, which parteth into two, bearing on each ſundry large ſpread flowers, of a deepe red Roſe colour, ending in tenne points, as if they were ſo many leaves, but before they open to be like a ſtarre, are plaited into ten plaites, each plait or fould being of a deeper colour, having twenty threads in the middle tipt with yellow, ſtanding about the middle umbone which becommeth the ſeede veſſell, and each flower ſet in a paler hairy huske pointed alſo: the roote is very ſmall and thready, yet thruſteth it ſelfe into the chinkes of the rockie and ſtony places, where ſcarce any earth is to be found.

6. *Sedum majus anguſtifolium.* Great narrow leafed Houſeleeke.

This kinde of Houſeleeke hath ſundry circles of leaves ſomewhat like the former ſort, but the leaves are narrower and longer, and a little rough or hairy withall; the ſtalke that riſeth from ſome of the heads is browniſh, and about a cubit high, ſet thicke with narrower and red pointed, fat thicke undented leaves up to the toppe, where it brancheth forth into ſome few, bearing each a flower of tenne or twelve long and narrow leaves, laid open like a ſtarre, of a reddiſh purple colour; the ſeede that followeth in ſo many ſmall heads, as there were leaves in the flowers, is as ſmall almoſt as duſt: the roote is reaſonable thicke, with divers ſtrings faſtened thereto.

7. *Vermicularis arboreſcens.* Tree Houſeleeke with ſmall leaves.

This kinde of Houſeleeke or Prickemadam, riſeth up to be five or ſixe foote high, as I have obſerved it when it groweth in Gardens, plentifully ſtored with branches from the bottome to the toppe, and ſet thicke with ſmall long and round greene leaves without any taſte, very like to thoſe of the ſmall Houſeleeke called Stonecroppe, or Prickemadame, (although *Lobel*, as I thinke ſaith it hath a ſaltiſh taſte) but leſſer and greener, the flowers grow at the toppes of the branches, ſmaller than in the next that followeth, and of a pale yellowiſh colour: the rootes are long wooddy and ſpreading in the ground: the branches hereof ſlipped and put into the ground will quickly take roote and grow.

8. *Vermicularis fruticoſa altera.* Shrubby Prickemadam.

This other ſhrubby plant groweth nothing ſo high as the former, not being above a foote high full of branches covered with an aſh coloured barke, as limber and pliant as it, the leaves hereof are ſomewhat greater and larger than the other, of a more ſaltiſh taſte, and of a darker greene colour: the flowers at the toppes of the branches are larger, but fewer, and of a yellowiſh colour, the roote is hard and wooddy.

The Place.

The firſt groweth in *Greece*, *Italy*, *Portugall*, *Spaine*, *Illyria* or *Slavony*, and ſome of the Iſles in the *Mediterranian* ſea, as *Scicily*, *Sardinia*, *Corſica*, *&c.* where it groweth naturally, but in divers places of *Italy*, *Portugall* and *Spaine*, it is kept, as *Cluſius* ſaith, in pots, and carefully preſerved in the Winter, & in *Liſhbone*, as he ſaith, upon the houſes as our common Houſeleeke, but will not endure the cold of theſe more Northren countries of Europe, with all the care that may be withont a ſtove, ſuch as they uſe in *Germany* and other places more Northerly; yet *Lobel* ſaith, he found it in the Iland of *Holmes* by *Briſtow*: the ſecond groweth by the ſea ſide in many places of this Land, and in the Ile of *Holmes* not farre from *Briſtow*: the third groweth naturally on divers hills in *Germany*, but with us onely where it is planted upon houſe ſides, &c. and that in clay eſpecially, for therein it will beſt thrive. The fourth, *Cluſius* ſaith, he found very common on the hills neare *Vienna* in *Auſtria*: the fifth *Columna* found in *Naples*: the ſixt *Cluſius* ſaith, he found on the Alpes neare *Saltzburg* in *Germany*, the two laſt groweth by the ſea ſide, and further off likewiſe where the laſt will taſte brackiſh as well as neare the ſea ſide.

The Time.

The firſt flowreth in *Portugall*, as *Cluſius* ſaith, in *November* and *December*, but never with us: the ſecond flowreth by the ſea ſide in *Auguſt*: the third, fourth, and ſixth, in *Iuly*; the fift in *May*; and the two laſt ſorts very late alſo.

The Names.

It is called in Greeke Αἰζοον τὸ μέγα, *Aizoon magnum* or *majus*, of the everliving and greeneneſſe thereof, and therefore *Gaza* tranſlateth it out of *Theophraſtus Sempervivum*, which is the ſame in ſignification; it hath likewiſe divers other names, for as *Pliny* ſaith, it was called *Buphthalmum Zoophthalmum*, and *Steigethron*, and *Hypogeſon*; ſome called it alſo, as he ſaith, *Oculus* and *Digitelius*: it is called by *Apuleius*, *Vitalis* and *Iovis barba*, but uſually, *Sedum majus*; the *Arabians* call it *Bejahalalem* and *Haialhalez*; the *Italians Sempervivo maggiore*; the *Spaniards Sempreviva herba puntera*; the *French Grande Ioubarbe*; the *Germans Hanſwurtz* and *Donderbaer*; the *Dutch Donderbaert* and *Huiſlook*; we in *Engliſh* generally Houſeleeke; yet ſome call it Sengreene, Aigreene, and ſome *Iupiters* Eye, Bullocks eye, and *Iupiters* beard. *Cluſius* and others doe certainely affirme, that our ordinary great Houſeleeke is the *Cotyledon altera* of *Dioſcorides*, and no one can diſprove their judgements therein. The firſt is the true *Aizoon magnum* of *Dioſcorides*; and others, and there is no doubt made thereof by any. *Matthiolus* and others call it *Sempervivum arboreſcens*, and *Sedum arboreſcens* and *Aizoon arboreſcens*: *Cluſius* calleth it *Sedum majus legitimum*: the ſecond *Lobel* maketh a kinde thereof, and calleth it *Sedum Portlandicum*: the third is moſt common with us, and is generally called *Sedum majus*, and *Sempervivum majus vulgare*, which as I ſaid, *Cluſius* calleth *Cotyledon altra Dioſcorides*; ſome alſo call it *Acetabulum*

lum majus, which peradventure is more proper to the first sort, and *Anguilara, Vmbilici veneris species altera*. *Cæsalpinus, Cassiæ lignæ similis frutex tertius*, who also thought it to be the *Selago* of *Pliny*, *Lobel* saith it may be *Chamæpeuce* of *Pliny* that is, *Picea humilis*; but *Selago* was called *Camphorata* by the learned of *Mompelier* from the smell of *Camfyre*, which the leaves being bruised give, but this hath no such smell, and therefore I thinke cannot be the *Selago* of *Pliny*, which is a different plant from this whereof I have spoken before, but it is probable that this plant is that which *Bauhinus* calleth *Sedum montanum Ericoides* as he saith himselfe; the last *Lobel* calleth *Sedum minimum arboreſcens vermiculatum*, *Bauhinus* maketh some doubt whether it might not be the *Polygonum masculum fruticosum* of *Thalius*, who saith he never saw the flowers, but saith it is not the *Poligonum alterum Serpillifolium Anglorum*, meaning *Lobel* and *Pena*, for so hee calleth them, because their *Adversaria* was printed in *England*.

The Vertues.

Our ordinary Houseleeke is cold in the third degree, moderately drying and binding, and is good for all inward heats as well as outward, and in the eyes or other parts of the body: a Possit made with the juice of Houseleeke is singular good in all hot agues, for it cooleth and temperateth the blood and spirits, and quencheth the thirst, and is also good to stay all hot defluxions of sharpe and salt rheume into the eyes, the juice being dropped into them, or into the eares helpe them, it helpeth also all other fluxes of humors into the bowells, and the immoderate courses of women: it is sayd also to kill the wormes, and to remedy the biting of the *Phalangium* Spider: it cooleth and restrayneth also all other hot inflammations, Saint *Anthonies* fire, and all other hot eruptions in the flesh, scaldings also and burnings, the shingles, fretting ulcers, cankers, tetters, ringwormes and the like, and easeth much the paine of the goute, proceeding of an hot cause: the juice also taketh away warts and cornes in the hands or feete being often bathed therewith, and the skinne of the leaves being layd on them afterwards: it easeth also the headach, and distempered heate of the braine in frensyes or through want of sleepe, being applied to the temples and forehead: the leaves bruised and layd upon the crowne or seame of the head stayeth bleeding at the nose very quickly. The distilled water of the herbe is profitable for all the purposes aforesaid: the leaves being gently rubbed on any place stung with Nettles or Bees, or bitten with any venemous creature doth presently take away the paine.

CHAP. VI.

Aizoon Sedum sive Sempervivum minus. Small Houseleeke.

THe next ranke of Houseleeks that I am to entreate of, are of those smaller sorts that grow with us elsewhere upon mudde and stone walls, or on dry sandy bankes or places, &c. whereof some are of a contrary qualitie, being hot, sharpe and exulcerating, whereunto I must adjoyne one other that groweth in moyst medowes, because it is so like them in the outward face.

1. *Vermicularis & Crassula minor vulgaris sive Illecebra major.*
The ordinary Prickmadam or Stonecrop.

The common Stonecrop groweth upon the ground with divers trayling branches, set with many thicke, fat, and somewhat round whitish or yellowish greene leaves, a little pointed at the edges: the flowers stand at the toppes of the branches, many set together, yet somewhat loosely and not in a thicke tuft or cluster as the Orpines, of a yellowish colour, the rootes are very small creeping in the ground, and send forth stalkes with leaves here and there all abouts.

2. *Vermicularis Scorpioides.* Stonecrop with turning heads.

This other Stonecrop or Prickmadam hath such like stalkes with leaves thereon as the former, that it is hard to distinguish them untill they come to flower, which then may be descerned to differ onely in the turning toppes, of yellow flowers bending or turning like the taile of a Scorpion, or those herbes that are resembled unto it: the rootes in like manner creepe and shoote forth in divers places. Of this sort there is another whose head of flowers turneth not, which *Lobel* calleth *Hæmatodes*. *Hæmatodes.*

3. *Vermicularis minor.* Small Stonecrop.

The small Stonecrop hath small and long leaves like the other, set upon short stalkes, not past an handbreadth long which are not so thicke but more flat, and of a more stipticke taste, the flowers are of a paler yellow colour and greater then the first, else standing in tufts in the same manner: the roote is like it also creeping about: this looseth both stalke and leafe in the Winter.

4. *Vermicularis flore albo.* white flowred Stonecrop with round pointed leaves.

The white flowred Stonecrop creepeth upon the ground in the same manner that the others doe, with slender stalkes and long round leaves upon them, of a blewish greene colour, not sharpe but round pointed, seeming like wheate cornes or pine apple-kernels, being sparsedly set thereon: at the toppes whereof stand small white starre like flowers in small tufts or sparsed umbells: the roote creepeth like the rest, and the leaves perish with the stalkes every yeare like the last.

5. *Vermicularis dasyphyllon.* A smaller white flowred Stonecrop.

This other Stonecrop groweth lower and hath more store of such small round leaves like wheate cornes, thicker set thereon then the other: the flowers are white also like the last, and in no other thing differeth from it.

6. *Sedum arvense sive palustre flore rubente.* Marsh or Field Stonecrop.

This Field Stonecrop hath divers reddish stalkes set with small fat long leaves, somewhat hairy, and much greener then any of the former: the flowers are small standing like starres, many in a tuft together, of a pale red or carnation colour: the roote is like the rest, sending forth divers shoots: this abideth greene all the Winter, and hath as little taste as the former.

7. *Illecebra minor sive Sedum tertium Dioscoridis.* Wall Pepper.

This wall Pepper is almost the smallest of all these, and groweth like the former with very many and slender stalkes, and small round leaves thicke set upon them, at the toppes whereof grow small pale yellow flowers

1. *Vermicularis ſive Craſſula minor vulgaris.*
Prickmadam or Stonecrop.

2. *Vermicularis Scorpioides, & non Scorpioides.*
Stonecrop with turning heads and without.

in taſts as the others doe: the roote in like manner creepeth about, ſending forth many ſtalkes, which as they lye upon the ground take roote and ſpread farre: the taſte hereof is very ſharpe and hot upon the tongue, which chiefely diſtinguiſheth it from all the reſt, but it may alſo bee diſtinguiſhed by the forme, being ſmall and thicke, ſet with round leaves.

8. *Illecebra inſipida.*
Vnſavorie Wall-Pepper.

This Wall-Pepper is as ſmall a plant as the laſt, growing altogether like it in leafe, ſtalke, and flowers, being yellowiſh likewiſe, but the taſte onely diſtingniſheth it from the other, which in this is nothing biting, but utterly unſavorie and without taſte.

9. *Sedum minus æſtivum.*
Summer Houſeleeke or Stonecrop.

This Summer ſort hath many thicke round long leaves ſet together without order, on the ſmall ſtalkes which branch themſelves into ma-

3. *Vermicularis minor.*
Small Stonecrop.

6. *Sedum arvenſe ſive paluſtre flore rubente.*
Marſh or Field Stonecrop.

7. *Illecebra minor sive Sedum tertium Dioscoridis.*
Wall-Pepper.

8. *Illecebra insipida.*
Vnsavorie Wall-Pepper.

ny; stored with many yellow flowers at the toppes: the roote is small and perishing.

The Place.

Although these sorts grow eyther on mudde or stone walls, or among rubbish, and in other sandy or gravelly places, and oftentimes also upon the sides of old tiled houses and penthouses, especially the two last sorts saving one: but the sixt onely groweth in moyst Medowes and Marshes.

The Time.

They all flower in *Iune* and *Iuly* and sometimes sooner, the leaves of many of them continuing greene all the Winter.

The Names.

These kindes of Houseleekes are called in Greeke Α'ειζωον το μικρον *Aizoon minus*, that is, *Sempervivum minus*, in that they are alwaies greene, and are lesser then the former, yet some do call both kinds *Aithales*; for that they are ever living, *Pliny* calleth this lesser kind *Trithales quia ter floreat* (but *Brunfelsius* referreth that name to the greater) and *Erithales* or *Erisithales* and *Chrysothales*. The *Italians* call the first *Semprevivo minore* & *Pignola*, the *French petite Ionbarbe* and *Triquemadame*, the *Germans Klein Hanswurtz* and *Klein Donderbaer*, the *Dutch Bladerlooſen* and *Pape cullekens*, and wee is *English* Prickmadam, Stonecrop, or great Stonecrop (because we call two of the last sorts small or little stonecrop) Stonehore and Mousetaile: The Wall-Pepper or country Pepper is called by the *Italians Granellete* and *Grafola*, the *French Pain d'ouscau*, the *Germans Maurpfeffer* that is *Piper murinum*, and *Catzentreubel*, that is, *Vua felium* or *felina*: the *Dutch Muerpepper*. The first is called by *Lobel* in his *Adversaria Vermicularis* of the likenesse of the leaves unto wormes, and *Classula minor officinarum sive Illecebra major*, it is the *Sempervivum minus primum* of *Dodonæus*, the *Sedum minus mas* of *Fuchsius*, and the *Sedum minus Hematodes* of *Tabermontanus* and *Gerard*: the second is called by *Lobel* in his *Icones* and *Dutch* Herball, *Aizoon Scorpioides*, and is the fourth *Sedum minus* of *Clusius*, and of *Camerarius Aizoon minus flore luteo reflexo*: the third is the sixt *Sedum minus* of *Clusius*, the *Sempervivum minus æstivum* of *Lobel*, and the *Aizoon medium* of *Thalius*: the fourth is the *Vermicularis flore albo* of *Camerarius*, the *Sedum minus fœmina* of *Fuchsius*, *Lugdunensis* and others, *Sempervivum minus album* of *Brunfelsius* and others, and is the first *Sedum minus* of *Clusius*: the fift is the seventh *Sedum minus* of *Clusius*, called by *Lugdunensis Aizoon Dasyphyllon sive densifolium*: the sixt is the third *Sedum minus* of *Clusius* called

9. *Sempervivum minus æstivum.*
Small Summer Houseleeke or Stonecrop.

called by him *Sedum paluſtre*, and is the fourth *Sedum minus* with *Tragus*, which *Bauhinus* calleth *Sedum arvenſe flore rubente*; although he would make it a differing ſort from it: the ſeventh is the eighth *Sedum minus ſive Cauſticum* of *Cluſius*, called *Illecebra minor* by *Lobel*, and *Sempervivum minimum*, and is taken by *Anguilara* to be the *Gramen* 3. *Plinij*; and of *Columna* to be his *Dactylon* 2. *vel* 3; and becauſe of the different qualitie, he judgeth it not fit to be accounted an *Aizoon* which are all cold; *Cordus* calleth it *Aizoon acre*, and *Thalius Aizoon minus fervidi guſtus*, who alſo calleth the eight *Aizoon minus* and *Vermicularis inſipida*, and by *Cordus Aizoon minimum*: the laſt is onely mentioned by *Lobel*.

The Vertues.

All theſe kindes of ſmall Houſeleekes or Stonecrops, except the ſeventh are cooling like unto the other greater Houſeleeks, and in their qualities are referred thereunto being ſomewhat aſtringent withall whereby they are no leſſe powerfull to ſtay the fluxes and diſtillations, bleedings inward and outward, eruptions in the skinne, cancerous and fretting ſores and ulcers, and generally can doe and performe whatſoever is ſaid of the greater kindes, and therefore in the want of the one, the other may ſafely and effectually be uſed; onely the laſt ſave one is fervent hot ſharpe & exulcerating (as I ſaid before) the skin, and raiſing bliſters if it be laid thereupon but a while, as forcibly as *Ranunculus* or Crowfoote will doe, and therefore it behoveth all that ſhall have occaſion to uſe any of the cooling Stonecrops, that they doe not miſtake this for ſome of them whereunto it is ſo like; yet it is not without ſome other good properties, whereof good uſe may be made, for it is ſaid to procure vomiting, the juyce thereof taken with vinegar and ſome other drinke, and thereby driveth forth thicke flegmaticke and collericke humours whereby quartaine agues, and other of long continuance may be cured. And that taken in the ſame manner, it doth expell any poyſon, or the force of venemous herbes, and of the Aconites, which yet is referred by ſome to the greater kindes: but *Caveat qui ſumpſerit*. *Dioſcorides* ſaith, that being outwardly applied with *Axungia*, that is Hoggs fuet, it will take away knottes and kernells, as well in the necke and throate, which is called the Kings evill, as in any other part of the body, and applied by it ſelfe, or boyled in oyle of Roſes, and the ſore piles annointed therewith, doth eaſe the paines, and cure them of the griefe.

CHAP. VII.

Aizoon, Sedum ſive Semper vivum minimum petræum & montanum.
Rockie and Mountainous ſmall Houſeleekes.

THe third kinde of ſmall Houſeleekes that I am to entreate of here, are of ſuch as grow on Rockie, ſtony, and mountainous places (of many whereof I have in my former Booke given you the knowledge) which are the leſt of all the reſt formed into circles or eyes, as the common Houſeleeke is, and as the ſorts of *Cotyledon altera* are alſo, whereunto they might be as well referred, but becauſe other Authors have ſet them forth by the name of *Sedum minus*, I am content to let them ſo paſſe alſo.

1. *Sedum minimum Alpinum Muſcoides*: Small Moſſelike mountaine Houſeleeke.

This ſmall Houſeleeke ſpreadeth with the many round circling heads of leaves like Houſeleeke, a great deale of ground ſo thicke lying thereon, as the Moſſe it ſelfe doth which leaves are very ſmall, thicke, and of a blewiſh greene colour: from the middle of divers of which heades ſpring up ſmall ſlender ſtalkes, not above two or three inches high, bare or naked of leaves, for the moſt part unto the toppes, where ſtand two or three ſmall white flowers made of five leaves apeece, and ſome yellow threds in the middle of them: the roote is ſmall and threaddy, but multiplieth it ſelfe into a number of heads.

2. *Sedum minimum Alpinum villoſum*. Small hairy mountaine Houſeleeke.

This is as ſmall an Houſeleeke as the former, growing in the ſame manner, and about the ſame height, but the

1. *Sedum minimum Alpinum Muſcoides.* Small Moſſelike mountaine Houſeleeke.
2. *Sedum minimum Alpinum villoſum.* Small hairie mountaine Houſeleeke.
4. *Sedum montanum gramineo folio alterum.* Another graſſelike ſmall Houſeleeke.

leaves

leaves are somewhat greater and longer, and set with small haires round about the edges; the stalkes also are hairy, and beare sixe or seven flowers a peece at the toppes which are white like the other, with a yellow bottome.

3. *Sedum minimum Alpinum gramineofolio.* Grasselike small Houseleeke.

This Houseleeke groweth not much higher than either of the former, the leaves of whose heads are somewhat longer than the last, flatter also and greener, very like unto the leaves of grasse, from among which riseth up a stalke or two, very small smooth and tender, about three inches long, bearing one flower, and sometimes two at the toppe, consisting of five white leaves, somewhat larger than the former, and their round ends dented in the middle, making every leafe seeme like a heart painted on the Cardes, the bottome of the flower being yellow.

4. *Sedum montanum gramineo folio alterum.*
Another Grasselike small Houseleeke.

This other small Houseleeke differeth little from the last in the manner of growing, smalnesse of the leaves, or height of the stalkes that beare flowers, but different in these points, that it beareth more flowers at the tops of the stalkes, not heartlike pointed, but whole, and of a pale yellow colour.

5. *Sedum petræum montanum luteum.*
Small rocke Houseleeke with yellow flowers.

This small rocke Houseleeke hath divers heads of leaves lying upon the ground like the other, but harder, narrower, pointed also and somewhat hairy: the flowers being foure or five that stand together, above on the naked stalkes about three or foure inches high, consist of foure small yellow leaves apeece, after which come long pointed flat coddes, somewhat like unto a Thlaspi, wherein is contained small browniſh flat seede.

6. *Sedum Alpinum grandiflorum.*
Small mountaine Houseleeke with great yellow flowers.

This small Houseleeke hath many small heads, of lesser leaves than those of the last, with small stalkes under them, from among which rise slender stalkes set with leaves up to the tops, where stand foure or five pale yellow flowers, larger than the smallnesse of the

7. *Sedum Alpinum flore pallido.*
Small mountaine Houseleeke with pale yellow flowers.

8. *Sedum minus montanum flore rubro.*
Small mountaine Houseleeke with red flowers.

11. *Sedum montanum perpusillum luteolis floribus.*
The least mountaine Houseleeke with yellow flowers.

13. *Sedum minimum Alpinum villosum alterum.*
Another small mountaine hairie Houseleeke.

Sedum montanum serratum guttato flore.
The Princes feather set forth in my former Booke.

plant might seeme to give, being almost as great as those of the white Saxifrage consisting of five leaves a peece, the roote runneth in the ground and spreadeth with many heads.

7. *Sedum Alpinum flore pallido.* Small mountaine Houseleeke with pale yellow flowers.

The neare resemblance of this small Houseleeke unto the small Stonecrops in the last Chapter, might justly have challenged the company: but because it is a mountaine kind, I thought better to place it here: It creepeth upon the ground with a number of small sappie branches of a hand breadth high, furnished round about with small long and pointed leaves, very like unto Stonecroppe, but somewhat flatter and not so thicke, and of a very stipticke taste, up to the toppes where stand many somewhat great flowers, yet much lesser than the last, of a pale yellow colour: the roote spreadeth much, whereby it greatly encreaseth.

8. *Sedum minus montanum flore rubro.* Small mountaine Houseleeke with red flowers.

This red flowred Houseleeke hath many small narrow and long leaves lying on the ground, among which riseth up a stalke about three or foure inches high, with a few leaves thereon, being longer and more pointed than those are below, and at the toppe divers large flowers made of many narrow and pointed leaves starre fashion, of a reddish colour and yellow in the bottome, with a white line at the bottome of each leafe, which are sweeter in smell that in any other sort.

9. *Sedum saxatile hirsutum purpureum.* Small hairie purple flowred Houseleeke.

This small plant hath sundry small hairy leaves set together, each whereof is lesser than those of Lentills, the stalke that riseth is slender and hairy, as the leaves that grow on them to the toppe are also, which is divided into small branches bearing every one a small purplish flower: the roote is small and threaddy.

10. *Sedum Saxatile atrorubentibus floribus.* Rocke Houseleeke with darke red flowers.

This small Rocke Houseleeke shooteth forth some slender stalkes, about two inches high, with small long leaves, set opposite thereon, and sundry flowers at the toppes of them, of a very darke red colour standing many together, as though they stood round in an umbell: the roote is small and long.

11. *Sedum montanum perpusillum luteolis floribus.* The least mountaine Houseleeke with yellowish flowers.

This least sort groweth into sundry small heads, very thickely stored with fine small leaves like Mosse on the ground, from which rise small slender stalkes scarse appearing with their heads above the leaves, each of them bearing but one pale yellow flower thereon apeece, rising from out of a large greene huske: the roote is long and slender, with many small fibres thereat, the whole plant above ground scarce attaineth unto two inches of height.

12. *Sedum saxatile variegato flore.* Small rocke Houseleeke with discoloured flowers.

Like unto the last small one is this variable coloured Houseleeke being as small as it, the leaves of whose heads also like Mosse upon the ground are small flat somewhat round, and of a pale greene colour: the stalkes are many that rise from among them, bearing every one a small flower of foure leaves apeece, diversely striped with white purple and darke red colours very delectable.

13. *Sedum minimum Alpinum villosum alterum.* Another small hairy mountaine Houseleeke.

This small Honseleeke hath many heads of small long leaves set with small haires about the edges, among which rise up small stalkes three or foure inches thicke, set with the like leaves, and three or foure small whitish flowers at the toppes,

The Place.

Most of these sorts grow upon the Alpes and *Pyrænean* Mountaines in divers places, but withall very hardly endure the transplanting into Gardens.

The Time.

They flower in *Iune* and *Iuly* in their naturall places, but earlier in Gardens when they will there abide.

The Names.

All these have beene lately found out, and are not mentioned by any of the ancient, but later Writers, and that

you

you may know whose each of them are, I will shew you their Authors: The first is the ninth *Sedum minus* of *Clusius*, the second his tenth, whereof *Gesner in hortis* maketh mention: *Bauhinus* thinketh it is the *Iasme montana* of *Lugdunensis*: the third is *Clusius* his eleventh *Sedum minus*: the fourth hath not beene exhibited by any before, the fift is the twelfth *Sedum minus* of *Clusius*, and called *Sedum petræum montanum* by *Lobel*, *Lugdunensis* setteth it forth for *Phyllon Arrhenogonon Dalechampij*, but both *Lobel* and *Clusius* taxe him for it: and *Gesner* also misliketh their judgement that would make any of these small *Seda* to be *Phyllon* of *Dioscorides*: *Columna* also misliketh that this should be accounted a *Sedum*, because the forme of the flowers and seede vessells doe differ from all the other sorts of *Sedum*, which although they be both great inducements and especially the seede vessells being as I have shewed in many places of this worke a precise note to know unto what *genus* the *species* of any herbe may best belong, yet in regard the manner of growing of these Houseleekes is so differing from all other herbes, and that this in the heads of leaves is so like unto them, I doe not see but that it may better bee referred to a *Sedum* then to a *Leucoium* as *Columna* doth, who calleth it *Leucoium luteum Azoides montanum*, making it a Wallflower; and indeede *Clusius* observing the difference, giveth a note thereof, and saith that it agreeth not in all parts unto the small Houseleekes, and therefore leaveth it to other mens judgements, to call it by some fitter name if they can: the sixt is the *Sedum minus tertium* of *Lobel*, *Dodonæus* calleth it *Sedum serratum* as *Bauhinus* thinketh as also to be the *Sedum Alpinum quartum* of *Columna*, but calleth it himselfe *Sedum alpinum Saxifragæ albæ flore sive grandifolium*, the seventh is the *Sedum minus sextum* of *Clusius*: the eighth is called *Aizoon montanum*, by *Lugdunensis*, and *by Bauhinus Sedum Alpinum rubro magno flore*: the ninth and tenth are remembred onely by *Bauhinus* and I from him: the eleventh hath not beene set forth by any Author that I know before: the twelfth is called by *Bauhinus Sedum saxatile variegato flore*, but is not that *Sedum flosculis partim candidis partim purpureis* that *Gesner in hortis Germanie* maketh mention of, for that I shall shew you by and by to be a *Cotyledon* with such flowers, which are all greater Plants then any of these *Seda minima*, the last also hath not beene remembred by any before. *Bauhinus* maketh mention of some more sorts of these small *Seda*, which I thinke are comprehended under some of the other sorts, and therefore not fit to be double repeated.

The Vertues.

All or most of these small Houseleekes being in taste drying and astringent, and some of them a little bitter withall doe testifie that they will well serve to helpe defluxions and to stay laskes and fluxes of blood or humors as powerfully as any of the other sorts, but are not so cooling: but because I have no author that hath set downe the properties of any of them in Physicke, either for inward or outward diseases, this therefore may bee sufficient for our nation (that are not likely to have much experience of any of them in our land) to have said thus much.

CHAP. VIII.

Sedum laciniatis foliis. Small Houseleeke with divided leaves.

I Cannot be brought to be of *Bauhinus* judgement, to make many sorts of this kinde of Houseleeke, for in my minde he forcibly draweth in other herbes to beare this title, which cannot fitly agree thereunto, as by the description of them in the precedent discourse, both in the second Chapter of the fourth Classis, and in the 40. Chapter of the fift Classis of this booke, and in other places you may more plainely perceive.

1. *Sedum Alpinum laciniatis Ajugæ foliis.* Small Mountaine Houseleeke with jagged leaves.

I cannot finde any more plants fitly in my minde to beare this title but this and another, and therefore I must give you the descriptions of these onely and leave *Bauhinus* or any one that will undertake to be his champion herein, to maintaine his other sorts as he can. This first shooteth forth on all sides many small heads of leaves from small strings like to the Houseleekes, each leafe whereof is long and narrow, cut in deepely into three divisions, one on each side and the end longest, somewhat like the leaves of the sweete Groundpine, but smaller and greener, not having any hoarinesse on them, astringent and drying also in taste as much as any of the other: the stalkes are reddish, very slender and not two inches high (saith *Clusius*, but they were higher with us) bearing every one of them one small flower but somewhat large with us) made of five leaves a peece, of a pale greene colour (so saith *Clusius*) but that which wee had from Mr. *Hesket* out of *Lancashire* bore pale whitish flowers with some yellow threds compassing a middle round umbone: the roote is small but spreadeth much.

1. *Sedum Alpinum laciniatis Ajugæ foliis*, Small Mountaine Houseleeke with jagged leaves.

2. *Sedum Monspelienſe & Pyrenæum laciniatum.* The *French* jagged mountaine Houseleeke.

This other jagged Houseleeke hath likewise divers heads of very small greene leaves, each whereof is deepely cut into two, or more usually into three parts, and seldome into more, from among which rise one or two small stalkes three or foure inches high, with some few leaves set thereon, parted very often into some branches, at the tops whereof stand foure or five flowers of five leaves a peece, of a pale colour, with divers threds in the middle: the roote is blacke and small, creeping about.

The Place.

The first saith *Clusius* groweth on the Mountaine called *Sneberg* or *Snowhill* among the stones, but on the Mountaines

taines of *Lancashiere* with us as Mr. *Hosket* told us, the other both upon Mount *Lupus* and *Calcar* neare *Mompelier*, and on the *Pyrænean* hills likewise.

The Time.

The first flowreth in *August* saith *Clusius*, within a while after that the snow is dissolved, but in the end of *Aprill* and beginning of *May* with us, although somewhat later in the naturall places, and the other much thereabouts.

The Names.

The first is mentioned by *Clusius* who in his Pannonicke observations maketh it his seventh *Sedum Alpinum Ajugæ folio*, and in his History of Plants setteth it for his *Sedum decimum tertium*: the other *Bauhinus* setteth forth by the name of *Sedum tridactylites Alpinum minus* and referreth it to the other sort of *Sedum Alpinum tertium* of *Gregorius de Reggio*, remembred by *Columna*, but so it cannot be, for he saith that that sort hath not leaves compact together as the other *Seda* but dispersed.

The Vertues.

You have heard before of the taste, and therefore you may judge of the qualities of these herbes, for I have no more to say of them, but that it is likely they be as effectuall for those causes that the last small sorts of Houseleekes are.

CHAP. IX.

Cotyledon primus sive Umbilicus Veneris. Kidneywort or Wall Pennywort.

THe last kinds of Houseleeke whereof I am to entreate, so to accomplish the whole family is of the Kidneyworts, whereof the first sort of *Dioscorides* being different from the other I will first speake of, and then of the rest that I have not mentioned in my former booke.

1. *Umbilicus Veneris vulgaris.* Our ordinary Kidneywort or Wall Pennywort.

The great Kidneywort or Wall Pennywort that groweth with us hath many thicke flat and round leaves growing from the roote, every one having a long footestalke fastned underneath about the middle thereof, and a little unevenly waved sometimes about the edges, of a pale greene colour, and somewhat hollow on the upper side like a spoone or sawcer, from among which rise one or more tender smooth hollow stalkes halfe a foote high, with two or three small leaves thereon usually not round as those below but somewhat long and divided at the edges; the tops are sometimes divided into long branches bearing a number of pendulous flowers, set round about a long spike one above another, which are hollow and like a little bell, of a whitish greene colour, after which come small heads conteining very small browniish seede, which falling on the ground will plentifully spring up before winter if it have moysture: the roote is round somewhat like the full roote of an

1. *Vmbilicus veneris vulgaris.*
Our ordinary Kidneywort or Wall Pennywort.

3. *Cotyledon altera minor folio subrotundo.*
Small Kidneywort with roundish leaves.

Orchis

Orchis or Doggestone, most usually smooth yet sometimes rugged or knobbed, grayish without and white within, having small fibres at the head of the roote and bottome of the stalke, altogether like an Orchis whereunto I would more nearely resemble the rootes then unto Houseleeke, but I must (not be singular although I speake my minde) herein follow others. Of this kinde wee have received from Doctor *Boelus* at *Lisbone* a greater sort, with paler greene leaves very beautifull, which Mr. *Tradescant* keepeth at *Lambeth*. *Major Lusitanicus.*

2. *Cotyledon sive Sedum montanum latifolium serratum guttato flore.*

Spotted Kidnywort, or the Princes feather.

This pretty kind of Houseleeke, or Kidnywort call it which you will is described in my former booke, where I call it the Princes feather, and therefore needeth not to be here againe repeated although I give you the figure of it among the rest: you shall finde the Figure hereof in folio 738.

3. *Cotyledon alter minor folio subrotundo.* Small Kidnywort with roundish leaves.

This other small Kidnywort hath much rounder and smaller leaves in the heads then the former, not so bigge as the nayle of ones finger, of as pale a greene colour as it, or more white and dented at the edges in the same manner, of an astringent taste like the other Houseleekes, from the middle of some of the heads yearely rise up slender but hard and rough stalkes about an handlength high, set with a few smaller and longer leaves thereon, at the toppes whereof appeare small flowers upon long footestalkes, consisting of five and sometimes of six leaves a peece, sometimes wholly white, and sometimes spotted with red spots, and sometimes having three purple lines running downe the backe of every leafe, so that it maketh the whole leafe seeme purplish, in their places follow small heads with small seede: the roote is small and fibrous like the rest, setting of heads of the like leaves round about it.

4. *Cotyledon alter versicoloribus floribus.* Small Kidneywort with party coloured flowers.

This small Kidnywort groweth with many heads of small leaves circlewise like unto the last Kidniwort (whereof it is a peculiar sort) greater then the smallest and smaller then the greatest, each whereof is somewhat long and narrow of a whitish greene colour dented as it were about the edges, or rather set with silver white spots about the edges making them seeme like white teeth (or as *Gesner* compareth them to the silver like fins of Fishes) very pleasant to behold, for in the Winter when no flower appeareth this and the last (and the first that I have expressed in my former booke, being all of one *genus*) giveth as much delight as when it is in flower, which are many standing on severall footestalkes, each leafe whereof is part white and part purple, variably diversified in every one of them.

The Place.

The first groweth very plentifully in many places of this kingdome, but especially in all the west parts of this land, upon stone and mud walls, upon rockes also, and in stony places upon the ground, at the bottome of old trees, and sometimes on the bodies of them that are decayed and rotten: the other of that sort in *Portugall* as is sayd; the second on the *Pyrenian* hills, the other two grow upon the rockes and among the very stones where there is scarse any earth for the rootes to abide, on the Alpes of the *Helvetians* or *Switzers*, and upon the hill called *Hortus Dei* neare *Mompelier*.

The Time.

The first doth usually flower sooner then the other, as at the beginning of *May*, and the seede ripening quickly after sheddeth it selfe, so that about the end of *May* usually the leaves and stalks are withered dry and gone untill *September* that the leaves spring up againe and so abide all Winter: the second about the middle of *May*, the other two sometime flower not untill *Iune* and *Iuly*, and their seede is ripe in *August*, those heads that bare stalks usually perishing together, and the other that bare not abiding all the extremity of the Winter.

The Names.

The first is called in Greeke κοτυληδὼν *Cotyledon ab acetabuli sive umbilici figura*, and therefore the Latines call it *Acetabulum* as well as *Cotyledon* or *Vmbilicus Veneris*: it hath also divers other names as *Scatum cæli*, *Scutellum*, *Terræ Vmbilicus*, *Hortus Veneris* and *Herba Coxendicum*: the *Italians* call it *Ombilico di Venere*, and some *Cupartivole*, that is *pot covers*, the *Spaniards Scudetes*, that is *Shields*, the *French Escueilles* and *Nombrill du Venus*, the *Germanes Loffelkraut* and *Navelkraut*, the *Dutch Navelcruijt*, and we in *English* of some Navelwort, or great Navelwort, Wall Pennywort, Hipwort, Kidneywort, *Venus*-Navell and Navell of the earth. The other is called of some in Greeke κοτυληδὼν ἑτέρα *Cotyledon alter* κυμβαλίον *Cymbalion*, and σκυτάλιον *Scytalium*, but they are rather referred to the former great Houseleeke, which I have shewed you before, and is the true *Cotyledon alter* of *Dioscorides* by the judgement of *Clusius* and others, the second is usually called *Sedum serratum* with most Herbarists: I have as you see joyned it here as fittest I thinke, but the other two last sorts have obtained that name of *Cotyledon* from *Matthiolus* who first called them so, and is still kept and held currant with many, yet confounded also with many others for the likenesse unto *Sedum minus*, as with *Cordus*, *Gesner*, *Camerarius*, *Dodonæus* and *Baubinus*, who often call them *Seda*, and very properly, for there is no herbe can so properly be called a *Sedum* as that which hath the leaves placed circle wise, one within another as they have, but because the *Cotyledon* is of that fashion it is I said justly termed a *Sedum*.

The Vertues.

The Wall Pennywort as *Galen* saith is of mixt qualities, that is, of moist and cold, somewhat astringent and a little bitter withall, whereby it cooleth, repelleth clenseth and discussеth, and is very effectuall for all inflammations and unnaturall heates, either inwardly to coole a fainting hot stomacke or an hot Liver, or the bowels or the mother, to drinke the juice or the distilled water, or else outwardly for pimples, redneſſe, Saint *Anthonies* fire and the like heates and inflammations, to apply the bruised herbe or to bathe the place with the juice or the distilled water: the said juice or water helpeth much also to heale sore kidneys, torne or fretted by the stone or exulcerated within and easeth the paines: it provoketh Vrine likewise, and is availeable for the dropsie: it helpeth also to breake the stone, and to coole the inflamed parts by the paines thereof, and other wringing paines of the bowels and the bloody flux: it is singular good for the painefull piles or hemorroidall veines, to coole and temper their heate and the sharpeneſſe of blood in them, and to ease their paines, to use the juice as a bathe unto them, or made into an oyntment by it selfe or with Myrrhe or other things conducible thereunto: it is no lesse effectuall to give ease of paines to the hot goute, the Sciatica and the inflammations and swellings in the cods, and

bringeth

bringeth againe the prepuce: it likewiſe helpeth the Kernells or knots of the necke and throate called the Kings Evill: it healeth Kibes and Chilblanes if they be bathed with the juice, or annointed with an ointment made thereof, and ſome of the skinne of the leafe laid upon them: it is uſed alſo in greene wounds to ſtay the blood and to heale them quickly: The leſſer ſorts are held to be cooling and ſomewhat more binding then the greater, and thereby availeable for thoſe diſeaſes whereunto thoſe qualities are proper.

CHAP. X,

Acetoſa ſive Oxalis. Sorrell.

SOrrell is accounted a Docke, and called the ſoure Docke, and therefore might have beene brought under the generall title of the Dockes: but becauſe none of the other Dockes are ſo cooling, nor planted in Gardens, I ſhall ſpeake of thoſe ſorts ſeverally hereafter, that I have not made mention of either before in this Worke, or in my former Booke. The ſorts of Sorrell are many more found out of late by the induſtrious ſearchers of Natures varieties, than formerly hath beene knowne, ſome growing naturally in our fields, ſome in our woods, ſome alſo in other countreis. Of the ordinary Sorrell nurſed in Gardens, which yet groweth alſo wilde in our fields and medowes throughout the Land, I have already entreated of in my former Booke, and ſhall not neede to ſpeake thereof againe here, but of the other ſorts, yet of the wood Sorrell, I ſhall ſpeake in the next Chapter, although for their forme ſake, they might have beene joyned with the reſt of the Trefoiles, whereof they are ſpecies.

1. *Acetoſa maxima Germanica.* Great Sorrell of *Germany*.

The great Sorrell of *Germany* groweth in the ſame manner that the ordinary Garden ſort doth, but the leaves thereof are much larger, and ſometime a little curled at the edges, the joynts of the ſtalkes are great and tuberous ſticking out like knots, which being taken from the ſtalke and put into the ground, will take roote, and bring forth leaves like the mother plant, the ſeede and ſo all other things are large anſwerable to the proportion of the leaves *Joannis Thalius* in *Hircynia ſylva*, maketh mention of a greater ſort of Sorrell than ordinary: & *Camerarius in horto*, of a great one received from *Spaine*, but neither of them ſpeake of any tuberous joints they ſhould beare, ſo that it is probable, it is but onely the climate and ſoyle that produceth the tubers.

2. *Oxalis ſativa Franca ſive Romana rotundifolia.* Round leafed Sorrell.

In the leaves of this Sorrell conſiſteth a cheefe difference which are ſhort and almoſt round in ſome, and in others they will have ſomewhat round pointed peeces on both ſides, of a paler greene colour then the former, the ſtalkes are weaker not ſtanding upright, but the flowers and ſeede differ not from the ordinary ſort: the roote is ſmall and threddy creeping about and ſhooting up heads of leaves round about: the

Acetoſa vulgaris.
Our ordinary Sorrell.

1. *Acetoſa maxima Germanica.*
Great Sorrell of *Germany*.

taſte

2. *Oxalis sativa Franca sive Romana rotundifolia.*
Round leafed Sorrell.

3. *Oxalis tuberosa radice.*
Tuberous rooted Sorrell.

7. *Acetosa Cretica semine aculeato,*
Candy Sorrell.

11. *Acetosa vesicaria Americana.*
Indian Sorrell with swollen huskes.

taſte is of a much more pleaſant ſharpeneſſe then the other, and therefore more deſired of any that formerly have uſed it.

3. *Oxalis tuberoſa radice.* Tuberous rooted Sorrell.

The cheefe differences in this conſiſt both in leaves and rootes, the leaves hereof being formed ſomewhat like the ordinary but larger and not ſo broad next the ſtalke, the ſtalks, flowers and ſeede are anſwerable to the former, but the rootes are many tuberous clogs faſtened by ſtrings to the head whence the leaves ſpring forth.

4. *Oxalis bulboſa montana major.* The greater bulbous Sorrell.

This bulbed Sorrell hath large greene leaves ſomewhat like the garden kinde, but more round at the further end, and more forked at the lower part next the ſtalke, that it ſeemeth almoſt three ſquare like unto an Ivie leafe, in the reſt it agreeth with the ordinary ſort but that the rootes are round and bulbous.

Bulboſa minor. There is another like hereunto, but that the leaves are leſſer and rounder, the whole plant ſmaller and lower alſo.

5. *Oxalis rotundifolia Alpina.* Small Mountaine round leafed Sorrell.

This ſmall Sorrell hath five or ſix ſmall leaves ſtanding upon very long and ſlender footeſtalkes, each leafe being no bigger then the nayle of ones hand, and in a manner as round as the Violet leafe: the ſtalke riſeth halfe a foote high, bearing ſuch like chaffie huskes and reddiſh, wherein the like ſeede unto the ordinary ſort lyeth.

6. *Oxalis ſcutata repens.* Creeping Sorrell with ſmall broad leaves.

This creeping Sorrell hath ſlender weake joynted branches trayling on the ground, foure or five inches long, whoſe leaves are ſmall, of a nailes breadth, and of the faſhion of a pointed ſhield, and pointed alſo at both ends, with very long footeſtalkes under them, the leaves being almoſt as long as the ſtalkes, in the taſte it is like the other ſmall Sorrells.

7. *Acetoſa Cretica ſemine aculeato.* Candy Sorrell.

The *Candy* Sorrell hath weake bending ſtalkes and ſometimes but one, branched forth on all ſides, the leaves are ſmall and long not broad or forked at the lower end as divers other Sorrells are, having long footeſtalkes under them: the toppes of the branches end in a long ſpike of ſmall moſſie flowers, which afterwards turne into ſmall thinne pricking huskes or skinnes wherein the ſeede lyeth, every one faſtned with a crooked footſtalke.

8. *Acetoſa Neapolitana Ocimi folio.* Sorrell of *Naples*.

This Sorrell of *Naples* ſhooteth up a ſtalke ſet with ſmaller thicke mealy leaves thereon than thoſe below, which are broadeſt in the middle, and ſmaller at both ends like the laſt, the toppes of the ſtalke endeth in a ſpike of greeniſh yellow flowers which turne into skinnie huskes, ſomewhat repreſenting, as *Columna* ſaith, the head of an Oxe with hornes ſtanding up, and eares handging downe, wherein lie the ſmall ſeede.

9. *Acetoſa Zacynthina Calthæfolio.* Marigold leafed Sorrell.

This Sorrell alſo hath no other difference therein from other Sorrells, but in the leaves which are broad pointed and ſomewhat long like a Marigold leafe without thoſe eares or points that the common Sorrell hath.

10. *Acetoſa Indica.*
Indian Sorrell.

This *Indian* Sorrell riſeth up with a ſlender weake hollow ſtalke, with a few long thicke leaves thereon, ſomewhat ſmaller than thoſe at the foote thereof next the ground, ſmall at both ends, and of a pale greene colour, of a delicate ſmall ſharpe taſte: at the toppe of the ſtalke grow ſundry browniſh ſmooth skinnes, with ſmall ſeede in them, the roote periſheth yearely.

11. *Acetoſa veſicaria Americana.*
Indian Sorrell with ſwollen huskes.

The *Indian* Sorrell hath ſlender ſtraked ſtalkes, of a cubite high, leaning downe to the ground, ſpreading into many branches, ſomewhat reddiſh towards the toppes: the leaves are ſmooth and thicke of a reaſonable ſiſe, ſomewhat like a Garden Sorrell leafe, but that the lower points are not ſo long, but rather ſhort like an Arrache leafe

13. *Acetoſa minor lanceolata.*
Sheepe Sorrell.

15. *Acetoſa anguſtifolia elatior.*
Tall narrow leafed Sorrell.

of a pale greene colour and ſomewhat mealy withall every one upon a very long foote ſtalke, and of a more ſharpe ſowre taſte than our Sorrell: at the toppes of the ſtalkes and branches ſtand the flowers in a long ſpike, like our ordinary Sorrell, but greater and of a greeniſh red colour: after which come round yet cornered skinnie ſwollen huskes hanging downewards, of a reddiſh colour, ſtriped with redder veines, very beautifull, wherein are contained two or three cornered browne and ſhining ſeede: the roote is ſmall and threddie, periſhing for the moſt part every yeare.

12. *Acetoſa Cambro-Britanica Montana.* Mountaine *Welſh* Sorrell.

The *Welſh* Sorrell groweth up with ſmall ſtalkes branched forth diverſly with round leaves ſet thereon, as alſo growing at the bottome of them every one upon a long footeſtalke, in ſhape ſomewhat like the Wall Pennywort, but that they are cut in at the lower part with ends on both ſides, the flowers hereof are whitiſh, and not red like others but the huskes with ſeede that come afterwards are reddiſh, and containe browne ſhining three ſquare ſeed like the reſt, the roote is ſmall and threddy, abiding many yeares.

13. *Acetoſa minor Lanceolata.* Sheepes Sorrell.

This is a ſmall Sorrell well knowne to many (growing in many medowes with us) not to differre from other ſmall Sorrells, but in the leafe which is ſomewhat ſmall and long broadeſt in the middle, and pointed at the further end, with two ſmall eares at the lower end of a pale greene colour ſomewhat whitiſh.

14. *Acetoſa minima.* The ſmalleſt Sorrell.

The ſmalleſt Sorrell that groweth moſt uſually on drie barren grounds is all together like the laſt, but ſmaller in each degree.

15. *Acetoſa anguſtifolia elatior.* Tall narrow leafed Sorrell.

This Sorrell may by the figure ſoone declare the variation, whoſe ſtalke is ſlender and tall, and the leaves narrow and long, yet formed like a Sorrell, as both flowers and ſeede.

The Place.

The moſt of theſe Sorrells beare in their titles or deſcriptions the places where they have beene found.

The Time.

All of them flower and ſeede in *May* and *Iune*, except the *Indian* ſort, which flowreth not untill *Iuly* for the moſt part, and the ſeede is ripe in *Auguſt*.

The Names.

It is called in Greeke ὀξαλὶς *Oxalis* of the ſharpe taſte, many of the Latine Writers keepe that name, in Latine alſo *Acetoſa*, and of ſome *Acedula* of the ſoureneſſe thereof, others call it *Rumex hortenſis*, and *Galen* calleth it ὀξυλάπαθον *Oxulapathum, id eſt, Lapathum acidum*, ſoure Docke, yet with *Dioſcorides*, *Oxylapathum* is *Lapathum Acutum*, that kinde of Docke whoſe forme of leafe is more ſharpe and pointed than others, and not for the ſharpe taſte to cauſe that name, the Sheepes Sorrell, is called *Lapatiolum* and *Acetoſella* by divers. *Cluſius* maketh mention of the firſt great ſort, and *Lobel*, *Dodonæus* and others of the ſecond, *Lobel* gave firſt of all others knowledge of the third, and *Columna* of the fourth; *Bauhinus* of the fift, ſixt, and ſeventh, *Columna* of the eight, *Proſper Alpinus* in his Booke of *Egyptian* plants of he ninth; of the tenth and laſt none hath made any mention before now *Beſlerus in horto Eyſtetenſi* ſpeaketh of the eleventh, by the name of *Acetoſa veſicaria peregrina*, which *Bauhinus* calleth *Acetoſa Americana folijs longiſſimis pediculis donatis*; but of the twelfth ſort (if it be not the ſame with the ſecond, whereunto it is very like) no author ever made mention before now, and ſcarce is it knowne to any but the Gentleman of *Angleſey* called Mr. *Morris Lloid* of *Priſlierworth* that found it on a mountaine in Wales, and ſhewed it to Dr. *Bonham* in his life: the thirteenth is called by *Matthiolus Tenuifolia*; and ſo by *Lonicerus*, *Geſner*, *Tragus*, & almoſt all other writers of herbes in our later age, and called *Oxalis vervecina* of *Lobel* and *Ovina* of others, and *arvenſis lanceolata* by *Bauhinus*; the fourteenth is remembred by *Montanus*, *Gerard*, and *Bauhinus*. All of them deſervedly have the name of Sorrell, becauſe howſoever they are ſomewhat different in leafe or roote, yet they all agree in the ſoureneſſe, although ſome more or leſſe than others. The *Arabians*, as *Serapio* ſaith, call it *Humaalh*; the *Italians Acetoſa*, the *Spaniards Azederas Azederilha* and *Agrethas*: the *French Azeille* or *Oſeille*, *Saltette*, *Surelle* and *Aigrette*; the *Germanes Sawrampffer*; the *Dutch Surckele* and *Surincke*; and we in *Engliſh* Sorrell.

The Vertues.

Sorrell is cooling and drying in the ſecond degree, and is prevalent in all hot diſeaſes to coole any inflammation and heate of bloud in agues peſtilentiall or chollericke or other ſickneſſes and fainting, riſing from heate, and to refreſh the overſpent ſpirits with the violence of furious or fiery fits of agues, &c. to quench thirſt, and to procure an appetite in fainting or decaied ſtomackes; for it reſiſteth the putrefaction of the bloud, killeth wormes, and is as a cordiall to the heart which the ſeede doth more effectually, being more drying and binding, and thereby alſo ſtayeth the hot fluxes of the menſtrues, or of humours in the bloudy flixe, or fluxe of the ſtomacke: the rootes alſo in a decoction or in powder, is effectuall for the ſaid purpoſes: both rootes and ſeede, as well as the herbe is held powerfull to reſiſt the poiſon of the Scorpion, ſo that he that ſhall eate thereof ſhall feele no paine being ſtung: the decoction of the rootes is taken to helpe the jaundiſe, and to expell gravell, and the ſtone in the raines or kidneyes: the decoction of the flowers made with wine and drunke helpeth the blacke jaundiſe, as alſo the inward ulcers of the body or bowells. A Syrupe made with the juyce of Sorrell and Fumiterrie is a ſoveraine helpe to kill the force of thoſe ſharpe humours that cauſe the itch: the juyce thereof with a little Vinegar, ſerveth well to uſe outwardly for the ſame cauſe, and is alſo profitable for frettings and gallings of the skin in any part, and for tetters, ringwormes, &c. it helpeth alſo to diſcuſſe the ſcrophules or kernells in the throate, and the juyce gargled in the mouth helpeth the ſores therein: the leaves wrapped up in a Colewort leafe, and roaſted under the embers, and applied to an hard empoſtume, botch, bile, or plague ſore, both ripeneth and breaketh it: the juyce of Sorrell dropped into the eares of ſuch as are hard of hearing helpeth oftentimes: the diſtilled water of the herbe is of much good uſe for all the purpoſes aforeſaid. The leſſer wilde Sorrell, and ſo all the other are of the ſame qualitie, and are no leſſe effectuall in all the diſeaſes before ſpoken of.

CHAP. XI.

Oxys, Alleluja ſive Trifolium aceteſum. Wood Sorrell.

THere arē two ſorts of Wood Sorrell, the one familiar enough in many places of this Land, the other a ſtranger as farre as I can learne, and onely cheriſhed in the Gardens of thoſe that are curious, I have as I ſaid brought theſe two ſorts from their family, where they might otherwiſe be ranked that is among the Trefoiles for their propertie and name alſo in part.

1. *Trifolium aceteſum vulgare.* Common Wood Sorrell.

The common Wood Sorrell groweth low upon the ground without any ſtalke riſing from it having a number of leaves comming from the roote made of three leaves like a Trefoile or Three leafed graſſe, but broade at the ends, and cut in the middle, of a faint yellowiſh greene colour, every one ſtanding on a long footeſtalke, which at their firſt comming up are cloſe folded together to the ſtalke, but opening themſelves afterwards, and are of a fine ſoure reliſh, more pleaſing than many of the former Sorrells, and yeelding a juyce, which will turne red when it is clarified, and maketh a moſt daintie cleare Syrup: among theſe leaves riſe up divers ſlender weake foote ſtalkes not growing above them, with every one of them a flower at the top, conſiſting of five ſmall and pointed leaves ſtarre faſhion, of a white colour in moſt places, or in ſome daſht over with a ſmall ſhew of bluſh, and in ſome but on the backe ſide onely: of any other colour (although ſome have ſet downe that it beareth deepe coloured flowers) I have not ſeene: after the flowers are paſt, follow ſmall round heads, with ſmall yellowiſh ſeede in them: the rootes are nothing but threads or ſmall ſtrings faſtened to the end of a ſmall long peece, all of them being of a yellowiſh colour not periſhing every yeare, but abiding with ſome leaves thereon in the Winter.

1. *Trifolium Aceteſum Vulgare.* Common Wood Sorrell.

2. *Oxys luteo flore.*

Wood Sorrell with yellow flowers.

This Wood Sorrell ſhooteth forth divers ſlender weake reddiſh ſtalkes trailing upon the ground, and taking roote at the joynts as they lie, ſpread into many branches with many leaves on them, ſtanding ſingly one above another, and made of 3. leaves cut in at the ends like the former, but are much ſmaller, and of a paler greene colour: at the joynts with the leaves come forth three or foure ſmall flowers together, at the end of a long foote ſtalke, yet each ſeparate from other, conſiſting of ſmall and pointed leaves like the other, but of a yellow colour: the ſeede that followeth is browniſh like the other, but contained in ſmaller and longer heads like cods or hornes, yet not crooked but pointed ſmall which quickly fall away being touched when they are ripe, and ſpring up againe all about where it grew; it abideth the Winter withou periſhing, if it be not too violent, elſe they will rot and periſh & muſt be new ſowne againe.

2. *Oxys luteo flore.* Wood Sorrell with yellow flowers.

The Place.

The firſt, as I ſaid, groweth plentifully in many places of our Land, in Woods, and Wood ſides where they may be moiſt and ſhadowed, and in other places that are not too much open to the Sun: the other groweth in divers ſhadowie places about *Sevill* in *Spaine*, and in Gardens at *Mompelier*.

The Time.

The firſt flowreth early in *Aprill* and *May*, the other after *Midſommer*, and ſo continueth in flower untill the *Autume* colds periſh it, and the ſeede is ripe in the meane time.

The Names.

It is generally taken to be the *Oxys* of *Pliny*, whereof he ſpeaketh in his 27. Booke, and 12. Chapter, but not the *Oxytriphyllum*, although *Tragus* and *Lacuna* did ſo call it, becauſe the name did ſomewhat agree thereto, but that it is an other herbe whoſe ſharpe pointed leaves, and not the ſharpe taſte cauſed this name, for ὀξὺ the Greeke

Greeke word doth ſignifie both ſharpeneſſe in forme and in taſte, It is called *Trifolium aceteſum* of divers, which is the ſame in ſignification as I ſaid with *Oxytriphyllum*, and of ſome *Panis Cuculi*, Cuckowbreade, eyther becauſe the Cuckowes delight to feede thereon, or that it beginneth to bloſſome when the Cuckow beginneth to utter her voyce; it is called by the Apothecaries in their ſhoppes *Alleluja* and *Lujula*, the one becauſe about that time it is in flower when *Alleluja* in antient times was wont to bee ſung in the Churches, the other came corruptly from *Iuliola* as they of *Calabria* in *Naples* doe call it, as *Scaliger* upon *Theophraſtus de cauſis plantarum* ſaith, yet it is there ſet downe *Alleluja*, but I thinke it rather ſhould be *Lujula*. The other is called *Oxys flore luteo* of *Cluſius*, and *Oxys lutea corniculata repens* of *Lobel*, and of *Bauhinus Trifolium acetoſum corniculatum*. The *Italians* call it *Trifolio acetoſo Pan cuculi* and *Alleluja*, the *French Pain de coqu*, the *Germans* Sawerklee, the *Dutch Coeckcoezbroet*, and we in *Engliſh* Wood Sorrell, Wood ſower, Stabbewort, and Sorrell *dubois*.

The Vertues.

Wood Sorrell is cold and dry as the other Sorrells are, and ſerveth to all the purpoſes that they doe, being as effectuall if not more, eſpecially in hindring the putrefaction of blood and ulcers in the mouth and body, and in cooling and tempering diſtempered heats and inflammations, to quench thirſt, to ſtrengthen a weake ſtomacke, to procure an appetite, to ſtay vomiting, and moſt ſingularly excellent in any contagious ſickneſſe or peſtilentiall Feaver, the Syrupe made of the juice is effectuall in all the cauſes aforeſaid, and ſo is the diſtilled water of the herbe alſo: Spunges or linnen clothes wet in the juice and applyed outwardly to any hot tumors and inflammations doth exceedingly coole and helpe them: the ſame juice taken into the mouth and there gargled for ſome time, and after ſpit forth and freſh taken, will wonderfully helpe a ſtinking foule Canker or Vlcer therein: it is alſo ſingular good in wounds, punctures, thruſts and ſtabbes into the body, to ſtay the bleeding and to cleanſe and heale the wounds ſpeedily, and helpeth well alſo to ſtay any hot defluxions or catarrhes upon the Throat and Lungs.

CHAP. XII.

Atriplex ſylveſtris. Wilde Arrache.

THe two ſorts of garden Arrache are already ſet forth in my former booke, there remaine divers other ſorts to be declared, as well ſuch as for their raritie and beauty wee nurſe up in our Gardens, as grow wilde, whereunto I would alſo joyne the Sea plant to ſet them all together.

1. *Atriplex baccifera rubra.* The red berried Arrache.

This beautifull ſmall plant ſendeth forth divers ſlender branches ſomewhat wooddy, about a foote high, or more or leſſe as the place where it groweth will produce, with a ſmall cornered leafe like the broad leafed wilde Arrache, ſet at the joynts one above another, and at every of the ſaid joynts with the leafe from the loweſt almoſt ſtandeth a ſmall red berry, cluſter faſhion, that is many ſmall graynes ſet together like a Mulberry, cleare and almoſt tranſparant, full of an excellent juice, as red as blood or Claret wine, which being bruiſed upon the backe of the hand while it is freſh will ſeeme as if you had drawne blood out thereof; which berry being dry groweth blackiſh, and containeth within it ſmall blackiſh ſeede, and will ſtill ſpring up every yeare, if it be ſuffered to ſhed: the roote is ſmall and fibrous periſhing after ſeede time.

2. *Atriplex ſylveſtris lappulas habens.* Wilde Arrache with ſmall berries.

This Arrache likewiſe is ſmall even ſmaller then the other, whoſe branches doe not exceede an hand breadth or halfe a foote at the moſt, ſet with ſuch like ſmall cornered and pointed leaves as in the other, every one ſtanding upon a ſhort footeſtalke, at every joynt with the leafe even almoſt from the bottome commeth forth two very ſmall berries or burres, of the bigneſſe of a Coriander ſeede, containing therein ſmall blacke ſeede like the laſt: the roote is ſmall and wooddy periſhing every yeare after ſeedetime. Of this kind there is another that beareth greater burres, leaves, and ſtalkes, not differing in any thing elſe.

3. *Atriplex ſylveſtris fructu compreſſo roſeo.* Wilde Arrache with flat Roſelike berries.

This other wilde Arrache hath a whitiſh hard round ſtalke, about a foote and a halfe high; ſpreading forth into many the like branches, and they againe ſhooting forth other ſmaller ones, which bow themſelves downe a little, whereon are placed ſmall hoary or mealy leaves, no bigger then the nayle of ones finger, waved and cut into corners on the edges, like the wilde Arrache called Gooſefoote, every one cloſing the ſtalke and branches without any footeſtalke; at every of theſe leaves commeth forth a moſt dainty broad and flat coloured fruite, made as it were of leaves, rayſed up a little in the middle, having foure other eminences at the brims or edges, yet ſo ſet as that the brims or edges are betweene them ſomewhat like unto the folding of the leaves in a Roſe as it is painted, in every one of which foure aforeſaid eminences is contained one flat ſeede of a reaſonable bigneſſe.

4. *Atriplex marina repens.* Creeping Sea Arrache.

This Sea Arrache creepeth upon the ground with many hoary white branches and mealy white leaves ſet on them without order, cut in on the edges or nere at the bottome, and pointed at the ends, ſomewhat like unto a ſmall Gooſefoote leafe; at the toppes of the branches grow divers ſlender hoary yellowiſh ſpikes of ſeede ſet cloſe together like cluſters: the roote is great with many ſtrings and periſheth not, and is of a ſaltiſh taſte although bred up in a Garden, ſometimes it will turne reddiſh like the Garden red Arrache and ſometimes nothing ſo mealy but rather greene.

5. *Atriplex maritima anguſtifolia.* Narrow leafed Sea Arrache.

It groweth up with an hoary and wooddy ſtalke a foote high, ſpread at the toppe into many ſmall branches ſpotted with blacke ſpots, which end in long yellow ſpikes of cluſtering ſeede like the former, the leaves that grow below are ſomewhat long and narrow about two inches long, of a darke greene colour with ſome corners about the edges but ſmaller as they grow higher.

6. *Atriplex ſylveſtris vulgatior ſinuata.* The greater common wild Arrache.

The greater common wild Arrache hath ſtrong round hard ſtalkes and branches, with large leaves on them like

1. *Atriplex baccifera rubra.*
The red berried Arrache.

4. *Atriplex marina repens.*
Creeping Sea Arrache.

6. *Atriplex sylvestris vulgatior sinuata major.*
The greater common wilde Arrache.

7. *Atriplex sylvestris angustifolia.*
Narrow leafed wilde Arrache.

8. *Atriplex ſylveſtre latifolia ſive Pes anſerinus.* Gooſefoote.

9. *Atriplex olida ſive ſylveſtris fœtida.* Stinking wild Arrache.

thoſe of the Garden, but not ſo broad or pointed at the bottomes, yet much waved or cut in on the edges, and of a durty mealy greene colour: the toppes of the branches are ſtored with long ſpikes of chaffie huskes, out of which come ſmall yellowiſh greene flowers, which afterwards give ſmall blackiſh ſeede like unto Purſlane: the roote is long ſomewhat wooddy and fibrous periſhing yearely. There is another hereof lower and leſſer in every part narrower alſo and a little waved on the edges, and periſhing in the like ſort. *Minor.*

7. *Atriplex ſylveſtris anguſtifolia.* Narrow leafed wild Arrache.

The ſtalkes of this wild Arrache are very much branched with ſomewhat long and narrow leaves ſet at the joynts, pointed at the ends, and ſmooth, without cuts on the edges, the long tufts of yellowiſh greene flowers ſtand in the ſame manner with the laſt and the like ſeede.

8. *Atriplex ſylveſtris latifolia ſive Pes Anſerinus.* Gooſefoote.

The ſtalkes of Gooſefoote are greene and ſomewhat creſted, with ſundry branches and great broad greene leaves ſet thereon, cut in ſomewhat deepe towards the bottomes of them, with long ſpiked flowers at their tops, of a reddiſh colour yeelding ſmall ſeede like the others.

9. *Atriplex ſylveſtris olida vel fœtida.* Stinking wild Arrache.

This hath ſmall and almoſt round leaves, yet a little pointed and without dent or cut, of a duſty mealy colour growing on the ſlender ſtalkes and branches that ſpread on the ground, with ſmall flowers in cluſters ſet with the leave, sand ſmall ſeede ſucceeding like the reſt, periſhing alſo yearely, and riſing againe from its own ſowing; this ſmelleth like old rotten Fiſh or ſomething worſe.

10. *Atriplex ſylveſtris Halimifolio.* Sea Purſlane leafed wilde Arrache.

The leaves of this wild Arrache are greater then the laſt, more mealy alſo and not ſtinking, ſet on ſtalkes that grow to be three or foure cubits high, with flowers and ſeede like the others and annuall alſo. Some other wild Arraches there are alſo differing little from theſe before ſet downe, but in being higher or lower according to the ſoile, or having ſmooth or waved leaves more or leſſe on the one ſide or both, which thus to have declared I hold ſufficiently ample to enforme you of them.

The Place.

The firſt came out of *Spaine* as it is thought: the ſecond groweth upon a hill of *Narbone* in *France*: the third under the walls of *Mompelier*, the fourth by the Sea ſide of our owne coaſts almoſt every where, the fift was found about *Rochel*; All the wild ſorts are found by walls, hedges, ditch ſides and out places, in many parts of the Land.

The Time.

They all flower in *Iune* and *Iuly*, and their ſeede is ripe quickly after.

The Names.

The Garden Arrache is called in Greeke Ἀτρᾰφαξις and Ἀδρᾰφαξις and Ἀδρᾰφαξὺ quod Ἀδρῶς αὐξει *Statim in amplitudinem adoleſcat & octavo die erumpit*: it is called alſo Χειροληχανον *Chryſolachanon, id eſt, Aureum olus*, in Latine *Atriplex* and *Atriplexum* as *Feſtus* hath it, and *Aureum olus*, it is called by the *Arabians Cataf* and *Caraf*,

by the *Italians Atriplice* and *Reppice*, by the *Spaniards Armoles*, by the *French Arroches* and *Bonnes Dames*, by the *Germans Milten* and *Molten*, by the *Dutch Melde* and *Mosscruyt*, and we in *English* Arrache, and some Orage, but corruptly. The first *Clusius* setteth forth by the name of *Atriplex baccifera*, and *Bauhinus Atriplex mori fructu*, the second and third *Bauhinus* setteth forth under the same titles they carry here; the fourth is called by *Lobel Atriplex marina repens lutea*, and *Xerampelina*, and by *Matthiolus*, *Dodonæus*, *Camerarius* and others *Atriplex marina*: the fift *Bauhinus* onely expresseth by the name of *Atriplex maritima angustifolia*: The wilde sorts are tearmed *Atriplices sylvestres* by all authors, *Thalius* calleth the greater and lesser of the sixt sort, *Atriplex Fimeteria maior & minor*, and *Lobel Sinuata*: the seventh is called by *Lobel Atriplex sylvestris Polygoni aut Helxines folio*, and *altera* by others: the eighth is taken to be a *Blitum* by *Tragus*, as also a *Solanum*, but generally by others *Pes anserinus* or *Chenopodium* by *Tabermontanus*, meaninng the Garden sort with purplish leaves as *Tragus* doth likewise: yet *Cæsalpinus* tooke it to be another sort of *Cynocrambe*: the ninth is called *Blitum fœtidum* by *Tragus*, and *Tragium Germanicum* by *Dodonæus* in his *French* Herball, but in his Latine *Garosmus* as *Cordus* doth, *Vulvaria* by some, but by most *Atriplex olida* or *fœtida*, yet some *canina* or *hircina*: *Cæsalpinus* onely calleth it *Cynocrambe affinis Cannina vulgo*: the last is called by *Lobel* in his Observations *Atriplex Halinodes*.

The Vertues.

Garden Arrache (for thereof also I shall relate the properties in this place, for that I have spoken but little of them in my former Booke, and because some of these former wilde sorts have not beene knowne availeable for any disease, being but lately found out, yet I doubt not but their temperature is correspondent to the other, their tastes being not much different from the common wilde sorts, which are neither so cold or moyst as the Garden kindes as *Galen* saith, and the Sea kindes somewhat hotter than the other, as you shall heare by and by) is cold in the first degree and moyst in the second, participating of a watery quality almost wholly, with little earthly parts therein, and lesse astriction, but as Mallowes quickly passe through the belly and thereby maketh it soluble, it hath also a small digesting quality therein, thus saith *Galen*. *Dioscorides* saith it is good for the yellow Iaundise, to drinke the seede with Mede or honyed water: *Lycus Neapolitanus* is sayd to give it against the danger that commeth to those that have taken *Cantharides*. *Matthiolus* saith that hee knew an Apothecarie that gave the seede Arrache to country people to drinke, which thereby purged them mightily both upwards and downewards, and that with much trouble also. *Hippocrates* applyed the juice thereof by a sering in the diseases of the mother: it cooleth hot apostemes and S. *Anthonies* fire, and dissolveth tumors applyed thereto either fresh or boyled: applyed with Vineger and Niter it easeth the paines of the goute and cureth scabbed nayles. The Sea Arrache is in propertie like unto the wilde sorts but by reason of the saltnesse doth more purge, and doth more trouble the belly then the other, being taken in the broth of fat meate, and helpeth those that have the Dropsie: it causeth leanesse in them that are too fat, and preserveth them from putrefaction. The common wilde Arraches are neare as cold as the Garden sorts, but more drying serving chiefely outwardly for inflammations: but Goosegrease is held much colder and therefore more warily to bee applyed, being held to bee dangerous if not deadly to be taken inwardly, and found certaine to kill Swine. Stinking Arrache is used as a remedy to helpe women payned and ready to bee strangled with the Mother to smell thereunto; *Hippocrates* also affirming that stinking or strong sented things are good for that disease: it killeth also the Wormes in the sores of Horses or other Cattle.

CHAP. XIII.

Beta. Beetes.

I Have entreated of divers sorts of Beetes in my former Worke, even of all that serve either as a sallet or pot herbe; there remaine some other sorts to be spoken of in this Chapter, and hereunto more fitly than any where else in my minde, doth the sorts of Spinage belong, although I know some do rather referre them to the Arrache simply, because it is most likest thereto in leafe, yet in nothing els, which *Matthiolus* misliketh; others unto *Lapathum* simply the Docke, as *Bauhinus*, who calleth them *Lapathum hortense seu Spinachia*, whereunto I can finde it in no part to agree but in being nursed up in Gardens: some againe finding them to agree to the Beete, especially in the seede and with the roote, as they thinke have entituled them *Sentlo Lapathum*, as if they would call it a Beete Docke; and others would referre them to the Docke and Mallow, calling them *Sentlomalache* for the solubilitie and slipperinesse they doe effect in the bowells, but I upon good ground, as I suppose, refusing all the former doe joyne them with the Beetes, and next to the Arrache, not onely for the formalitie of the seede unto the Beete, yet in some more rough or prickly, but of the leafe also, although Spinage be more torne at the bottome of them: if any mislike this my opinion, let them keepe their old wayes still whatsoever it be. I have thought good therefore to give you the figure of Spinage here in the forepart before the Beetes.

1. *Beta Cretica spinosa.* Prickly Beetes of *Candy*.

This *Candy* Beete spreadeth many long and straked branches upon the ground, of a cubit long full of joynts, with somewhat long broad and round pointed leaves, covered with a small hoarinesse, set upon long foote stalkes, like unto the leaves of the Blite, or small red Beete: from every joint, even the lowest, it spreadeth forth branches unto the toppes, and at every of them stand divers small and greenish browne hard huskes termined into three sharpe and hard prickes, out of which starte forth small yellowish greene flowers, and after they are past one small round seede in every of those huskes covered with a reddish skinne; the roote is small, long, round, and fibrous, dying every yeare, it giveth seede, or otherwise be hindered from bearing, for it seldome abideth a Winter although it seede not.

2. *Beta sylvestris maritima.* Sea Beetes.

The Sea Beete hath such like darke greene leaves as the ordinary Beete hath with some red veines in them, and some without; some also having reddish stalkes, and others greene, but they are smaller, narrower, and somewhat

Spinachia. Spinage.

1. *Beta Cretica spinosa.* Prickly Beetes of *Candy.*

Beta rubra sativa. Garden red Beetes.

4. *Beta platicaulos.* Flat stalked Beetes.

what thicker alſo than the Garden kinde; in other things it differeth little from it: neare the ſea this hath a brackiſh taſte, but nothing ſo much being tranſplanted.

3. *Beta lutea Syriaca.* The yellow Beete.

There is alſo from ſome parts of *Syria*, brought unto us and nurſed up in ſome curious gardens, a yellow Beete whoſe roote is of a paler yellow colour than a Carrot, the leaves alſo being of a yellower greene than thoſe of the ordinary white Beete.

4. *Beta platicaulos.* Flat ſtalkēd Beetes.

Sometimes there hath beene ſeene a degenerated kinde of Beete, whoſe ſtalkē was broad from the middle to the toppe brancing forth on all ſides, and foure inches broad at the higheſt, all the leaves being ſmaller than ordinary and ſo thicke ſet thereon upwards, that the ſtalke could ſcarce be ſeene, eſpecially at the toppes where the ſeede ſtood.

The Place.

Their places are ſpecified in their titles or deſcriptions, yet *Geſner in hortis* ſaith, that hee had it from credible perſons, that the yellow kind is found about the cities *Durachium* and *Alexium* in *Macedonia*.

The Time.

They doe all flower in the beginning of *July*, and their ſeede is ripe in *Auguſt*.

The Names.

Beetes are called in Greeke τεῦτλον and σεῦτλον, *Teutlon and Seutlon, ab impulſu quod facile excreſcat, in Latine Beta, quoniam figuram literæ β dum ſemine turget referre videtur*, which *Columella* in his tenth booke remembreth in theſe Verſes.

Nomine cum Grajo, ceu litera proxima primæ,
Pangitur in cera docti mucrone magiſtri,
Sic & humo pingui ferratæ cuſpidis ictu
Deprimitur folio viridis, pede candida Beta.

It is called by the *Arabians Decka* and *Calb*, by the *Italians Bietola*, by the *Spaniards Aſelgas*, by the *French Bete Iove*, and *Poeree*, by the *Germans Mangolt* and *Pieſſen*, by the *Dutch Beete*, and wēe in *Engliſh Beete*: the white Beete was called in former times *Sicula*, and in the later *Sicla*: there hath beene ſome doubt among many what Beete the ancients meant by the blacke Beete, ſome thinking the greene beete being of a darke greene colour ſhould be it, but others take the common red Beete to be it, which by the darke red colour commeth neareſt thereunto, which opinion I take to be the more certaine. Beetes were onely planted in Gardens, and no wilde kinde found with the ancients, as *Galen* ſaith, for although *Pliny* might thinke that *Limonium* was a kinde of the wilde Beete, yet *Dioſcorides* did not ſo account it, but made it another quite differing kinde of herbe, and gave thereto other manner of properties: yet at this time, as you ſee in this Chapter there are three ſorts ſet forth growing wilde of their owne nature. Divers doe call the firſt *Blitum ſpinoſum*, becauſe the leaves doe as neere reſemble a Blite as the Beete. *Lobel* maketh mention of the ſea kinde, *Camerarius in horto* of the yellow, and ſo doth *Geſner in hortis Germiniæ*, who ſaith that in *Syria* it is called *Skandar*, and that *Ebenbitar* the *Arabian* numbreth it among the ſorts of Rapes or Turneps; and that *Bellunenſis* likewiſe mentioneth it upon his Gloſſes or Comments on *Avicen* in the Chapter of *Sicla nigra*. *Lugdunenſis* calleth the laſt as it is in the title. The Spinache which I have here joyned with the Beetes, is called by moſt *Spinachia*, and by ſome *Spinaceum olus*: ſome of the later Greekes doe call it σπάναχα *Spanachia a raritate in uſu medico*; and ſome *Spanachia* in *Latine*, as *Matthiolus*, and thoſe that follow him, who I thinke firſt ſo called it, becauſe *Tragus* called it *Olus Hiſpanicum*, ſuppoſing as many others doe that it firſt came from *Spaine* to us.

The Vertues.

Simeon Sethi and divers of the ancients have ſet downe in their writings that Beetes have an hurtfull qualitie in them for the ſtomacke, and breede many diſeaſes: they have indeede a more nitrous qualitie whereby they provok more to the ſtoole than Arrache, Lettice or Mallowes doe, eſpecially the white: for the red Beete is held good to ſtay the bloudy flixe, womens courſes, and the whites, and to helpe the yellow jaundiſe; the white being more clenſing, digeſting, and provoking urine alſo, and the red more aſtringent, eſpecially the roote: the juyce or the roote put into the noſtrils purgeth the heade, and helpeth the noiſe in the eares, as alſo the tooth ach: the juyce of the white Beete openeth obſtructions, both of the liver aud ſpleene, and is good for the head ach, the ſwimming therein, and the turnings of the braine, and is effectuall alſo againſt all venemous creatures: the juyce of white Beetes applied upon the temples ſtaieth the inflammation in the eyes, the ſame alſo helpeth burnings being uſed without any oyle, and if a little Allome be put unto it, it is good for Saint *Anthonies* fire: the ſame alſo is good for all wheales, puſhes, and other bliſters and blanes in the skinne: the herbe being boyled and laid upon chilblanes on the hands, or kibes on the heeles helpeth them: it healeth the itch alſo if the places be bathed with the decoction of the herbe in water and ſome vinegar: the ſame doth likewiſe clenſe the head of dandraffe, ſcurfe and drie ſcabbes; and doth much good alſo for fretting and running ſores, ulcers and canckers in the head, legges or other parts; it is much commended alſo againſt baldneſſe and ſhedding of the haire. The wilde Beetes that are here ſet downe have not beene applied to any uſe that I know as yet; neither did I ever heare or reade of any Phyſicall properties of the Spinage.

CHAP. XIV.

Blitum, Blites.

VNto the Beetes doē the Blites requirē to be next joyned, of divers whereof I have ſpoken in my former Booke, namely of the Garden ſorts white and red beſides the *Amaranthus*, or Flower gentle of divers ſorts, whereof I meane not further to relate here, although I may give you ſome of their figures: but of ſome other ſorts nor there remembred.

1. *Blitum album ſylveſtrum minus.* The ſmall wilde white Blite.

The ſmall wilde white Blite groweth ſmall and low, with ſmaller whitiſh greene leaves ſet in the ſtalkes, than the

the greater ſort of the garden: the flowers and ſeede are like it alſo, and the roote but ſmaller in every part.

2. *Blitum rubrum ſylveſtre minus.* The ſmall wilde red Blite.

The leaves of this ſort are ſometimes and in ſome places more red than in other, and giving a fine red juyce as fit to write with (being ordered accordingly) as the red incke made of Braſſill, this is in all other things like unto the greater garden red kinde.

3. *Blitum Polyſpermon.* Wilde Blites with much ſeede.

The lower leaves hereof are very like unto the leaves of the former wilde ſort, yet a little rounder and ſmaller alſo on the ſtalkes that are much branched, at the toppes whereof grow long and ſpikie greeniſh heads of ſeede very thicke ſet together ſeeming to be all ſeede, whereof came the name *Polyſpermon* and is like unto the others: the rootes are wholly white and ſomewhat long.

4. *Blitum Virginianum majus.* The greater *Virginian* Blite.

This *Virginian* Blite riſeth up with one great thicke round, yet almoſt ſquare tall ſtalke five or ſixe foote high, full of ſmall branches on all ſides from the bottome to the toppe, ſet with larger leaves than in any of the garden kindes, and of a ſad greene colour, elſe ſo like them, that they plainely declare themſelves: the ſeede groweth in ſmall ſpikes, at the toppes of the ſtalke and branches which being ripe is ſmall blacke and ſhining like the reſt.

5. *Blitum Virginianum minus Amaranthi ſpecies.* The ſmaller *Virginian* Blite.

The ſmaller ſort of *Virginia* is very like the laſt ſort but much ſmaller and lower, having ſtalkes and leaves ſomewhat reddiſh with the greene, branched alſo but leſſe, and with ſmall long tufts of reddiſh ſoft ſcales as it were, and ſmall blackiſh ſomewhat ſhining ſeede afterwards, but neither ſo blacke nor ſhining as the laſt: the roote is ſmall and fibrous periſhing every yeare, yet often is raiſed againe from its owne ſowing.

6. *Amaranthus coccineus elegans maximus.*
The greateſt ſcarlet Flower gentle.

This great Flower-gentle riſeth up with very great thicke round tall ſtalkes, rather higher and greater than the moſt ordinary great red Flower-gentle, with as large great leaves on it, or rather bigger, but both the ſtalkes and they are of a freſh yellowiſh pale greene colour, with very little or no redneſſe in them at all (and this is one proper marke to know this ſort from others before it come to flower) the flowers ſtand at the toppes of the ſtalke and branches more ſpread at the bottome into ſundry parts, the middle being longeſt, and uſually when it is in the perfection hanging downe like a taſſell, the other parts like ſhorter ſpikes compaſſing it round which even for the proportion is very beautifull, but much more for the colour which is of a more excellent bright ſcarlet red colour, which being gathered in the prime will hold the colour a good while before it decay, eſpecially if it be kept from the Sunne and windie aire: the ſeede incloſed in theſe tufts is almoſt as white and ſmall as the great red ſort, yet a little redder whereby it may be knowne to differ. The deſcriptions of the other ſorts of *Amaranthus* are extant in my former Booke.

The Place and *Time.*

Some of theſe grow in our owne land in divers waſt places, and in gardens alſo as a weede, namely the three firſt ſorts; the other ſorts are brought us from ſundry parts beyond ſeas, as the fift from *Virginia*, & the laſt from *Braſill*, or ſome other part of *America*, and ſeede in *Auguſt* & *September*.

The Names.

All our moderne Writers (for none of the ancients have made any mention of them) doe agree in calling them *Blita ſylveſtria minora*, and the firſt two ſorts *Blitum ſylveſtre minus album & rubrum*; yet *Tragus* calleth the red ſort *nigrum*, and ſaith it is called *Sanguinaria* by ſome, which word *Sanguinaria*, is as he ſaith referred to five ſeverall ſorts of herbes, every country having their proper *Sanguinaria*, which are this wilde red or blacke Blite, Tormentill, Shepherds purſe,

1. *Blitum minus album ſylveſtre.*
The ſmall wilde white Blite.

2. *Blitum minus ſylveſtre rubrum.* The ſmall wilde red Blite.

3. *Blitum Polyspermon.*
Wilde Blites with much seede.

Amaranthus tricolor.
Variable Flower-gentle.

Amaranthus Coccineus.
Scarlet Flower-gentle.

6. *Amaranthus coccineus elegans maximus.*
The greater scarlet tufted *Amaranthus* or Flower-gentle.

Purſe, Knotgraſſe, and the Cockes foote graſſe: the third is taken by *Anguillara* to be the *Polyſporon* of *Caſſianus Baſſanus*, and by *Lobel* and *Lugdunenſis Polyſpermon*: the three laſt ſorts have not beene remembred by any author before me.

The Vertues.

The generall tenet of moſt as well in theſe plants as in all other is that thoſe which have red flowers ſeedes or roots, are good to ſtay the red courſes in women, and all other fluxes of blood in man or woman, and thoſe that be white will ſtay the whites in women or the *Gonorrhæa* in men, which although it may fall out right in ſome things, yet that it ſhould hold good in all, I am not certaine my ſelfe, nor can I aſſure any other, yet the qualities of all theſe being cooling, drying and binding, doe by *Hypocrates* teſtimony ſerve to reſtraine the fluxes of blood in man or woman. *Caſſianus* hath ſet it downe for an experiment, and *Anguilara* confirmeth it, that Fiſhes are much delighted with the third ſort here expreſſed, and by that baite are uſually taken.

CHAP. XV.

Viola. Violets.

I Have given you in my former booke all the ſorts of Violets and Panſyes either ſingle or double that are fit to furniſh a garden of delight and pleaſure: there are yet ſome other wilde ones of both ſorts to bee entreated of, which I have ſet downe together in this Chapter.

1. *Viola ſurrecta purpurea.* Vpright Violets.

This Violet groweth about a foote high or more, with hard upright ſtalkes, which yet bend downe againe their tops, having two leaves ſomewhat round ſet at each joynt but longer and more dented about the edges then the Garden kinds, at which joynts with the leaves on both ſides of the ſtalkes commeth forth a larger flower and more ſpread open then it, being more like a Panſye, but of a pale purpliſh colour, almoſt as ſweet as the Violet as *Matthiolus*, but without ſent as *Lobel* ſaith: *Dodonæus* maketh mention of this ſort as I take it, but he deſcribeth it with varietie of colours like a Panſye and therefore calleth it *Viola aſſurgens tricolor*, and ſaith *Matthiolus* ſet it forth to grow on Mount *Baldus*, but *Matthiolus* declareth no varietie of colours in his but purple: after the flowers are paſt follow longer ſeede veſſells then either the Violets or Panſyes have, wherein is contained as ſmall ſeed as that of the Panſyes but whitiſh, the roote conſiſteth of ſtrings which abide not after ſeedetime, but riſeth of the fallen ſeede.

1. *Viola ſurrecta purpurea.* Vpright Violets.

2. *Viola montana pumila anguſtifolia.* Small narrow leafed Violets.

This ſmall Violet ſendeth forth divers long and narrow leaves, ſomewhat like unto Roſemary leaves for the narrowneſſe and length alſo almoſt, among which come flowers every one ſingly on a ſmall long footſtalke very like unto a Violet, and of a whitiſh colour but without any ſent at all, the roote is ſomewhat thicke like unto Violets with divers fibres ſet at them.

3. *Viola montana laciniato folio.* Mountaine Violets with jagged leaves.

This jagged Violet bringeth out five or ſix leaves from the roote, every one upon a long footſtalke, more cut in on the edges then the common ſorts into five or eight diviſions, like unto a Crowfoote leafe or rather unto a broad leafed Anemone, betweene which leaves riſe ſeverall ſmall ſtalkes and flowers on them, but of what colour is not yet knowne but there were ſmall round heads found which had conteined the ſeede like unto the ſeede veſſells of Violets: the roote was ſomewhat great and of a fingers length.

4. *Viola lutea Virginiana.* Yellow Violets of Virginia.

The *Virginian* yellow Violet is very like our yellow Violet remembred in my former booke, and ſo is the ſmall yellow flower.

5. *Viola rubra ſtriata Eboracenſis.* Yorkeſhire ſtriped red Violets.

Maſter *Stonehouſe* a reverend Miniſter of *Darfield* in Yorkeſhiere aſſured me he found a kind of wilde Violet neare unto his habitation, whoſe leaves were rounder and thinner then of others, and the flowers reddiſh with ſadder veines therein.

6. *Viola ſylveſtris.* Wilde Violets.

The wilde Violet is altogether like the garden Violet, but that the leaves are fewer in number, ſomewhat thinner alſo and ſmaller and a little longer or not fully ſo round, the flowers alſo are larger and of a very pale purpliſh blew colour neare unto a watchet, not having any ſmell at all or very little.

7. *Viola tricolor ſylveſtris.* Wilde Panſyes or Hearts eaſe.

There are two or three ſorts of theſe wilde Panſyes not differing one from another, or any of them from the Garden kinde in forme of leaves, flowers or manner of growing, but in the colour and largeneſſe of the flowers,

Viola tricolor major & vulgaris.
Greater and leſſer Panſyes or Hearts eaſe.

7. *Viola ſylveſtris Tricolor.*
Wilde Panſyes or Hearts eaſe.

all of them for the moſt part being ſmaller then thoſe of the Garden, and of as ſmall a ſent, that is none at all, bu in the flowers the colours are divers, yet ſcarſe a flower among many hath three colours in them for they ar chiefely white and pale blew, more or leſſe marked and ſpotted, and ſometimes ſome yellow in the bottome.

The Place.

The firſt as is before ſayd was found upon Mount *Baldus* as alſo upon the *Veganean* hills in *Narbone*: the ſecon was found in *Spaine* by *Guillame Boel* as excellent an Herbariſt as any in his time, who ſhewed it both to *Cluſius* as he ſaith himſelfe among many other rare plants hee brought from thence: the third *Cluſius* ſaith hee had fro Docter *Mera* who gathered the plant in his returne from *Italy*, and ſhewed it dry to *Cluſius*: the fourth cam from *Virginia*, and the fift from *Yorkeſhiere* as is ſayd in the deſcription, the two laſt grow wilde in our own Land plentfully enough, the wild Violets in woods and Orchards and under buſhes upon heaths and ſuch like ſhady places, the wilde Panſies in the Corne fields and in ſuch as lye Ley, and in the borders of others fields.

The Time.

All theſe flower after the Garden Violets, and as the Panſyes untill the end of *Iuly*.

The Names.

The Garden Violet is called in Greeke ἰον πορφυρεῦν *Viola purpurea* by *Dioſcorides* and ἰον μέλαν *Viola nigra* and μελάνιον *Melanium* by *Theophraſtus* beleeved by the ancient Greekes (for ſo ſet downe in their writings) to be ſo called of *Io*, who was transformed into a Cow by *Iupiter*, the earth being cauſed to bring forth that herbe for cattle to feede on: or as *Hermolaus* reporteth *Nicander* to ſay in his *Geoponicks*, that the Violet was called *Ion* of certaine Nimphes of *Iouia*, who firſt gave of thoſe flowers to *Iupiter* as a preſent: the Latines doe call it, *Viola Martia*, and the herbe *Violaria*, *Viola quaſi vitula* by putting the Letter *t* in imitation of the Greekes, which made *Servius* to thinke that *Viola* was *Vaccinium* of the Latines, citing *Virgill* in his ſecond Eclogue *Alba liguſtra cadunt Vaccinia nigra leguntur*. But *Virgill* in his tenth Eclogue ſheweth he did not meane them, for hee nameth them both as different herbes in theſe words *Et nigræ Violæ ſunt & Vaccinia nigra*: but I have ſhewed what is the true *Vaccinium* of *Virgill* in my former booke in folio 127. and 128. *Vitruvius* alſo in his ſeventh booke of Architecture diſtinguiſheth *Viola* from *Vaccinium*, by ſhewing the different colours they gave in dying of cloth, &c. whereof came *Ianthinus* colour, A Violet or purple colour, ſome others thinke that ἰον came ἀπὸ τῦ ἰέναι, *quaſi ire, aut provenire, aut primum prorumpere*: *veris enim prævia eſt Viola*. The *Arabians* call it *Seneffigi*, *Senefragi* or *Benefiſigi*: the *Italians Viola porporea* and *Pavonazzo* and *Viola mamuolo*: the *Spaniards Violetta*: the *French Violette de Mars*: the *Germanes Mertzen Violen*, the *Dutch Violetten*, and we in *Engliſh* Violets, *March* Violets, and purple Violets: The Hearts eaſe is called by us Panſyes from the *French* word *Penſees*, as alſo love in idleneſſe, cull me to you, and three faces in a hood, and in Latine *Viola tricolor*, and *Viola flammea*, for ſo, that is *flamma*, *Gaza* tranſlateth φλὸξ or φλόμον, (φλόμινον ſome copies have) of *Theophraſtus lib. 6. c. 6.* ſome alſo call it *Viola multicolor Herba Trinitatis*, *Flos Trinitatis* and *Viola Trinitatis* of the three colours herein: *Matthiolus* alſo ſaith it was called *Iacea*, but there is another *Iacea* called *nigra*, whereof I have largely entreated before, and ſome call it

Herba

Herba Clavellata: the *Italians* call it *Iacea Fior di Giove* and *Minuti penſieri*, the *French* as I ſaid before *Penſees* and *Penſees minutees* the *Germans Freyſchemkraut*, the *Dutch Penſeen*. The firſt is called by *Matthiolus Viola arboreſcens*, by *Geſner Viola fruticoſa*, by *Cluſius Viola Elalior*, by *Lobel Viola Martia ſurrectis caulículis*, by *Dodonæus Viola aſſurgens tricolor*, by *Lugdunenſis Mater violarum*, and by others *Viola elatior* and *arborea*: the ſecond is called by *Cluſius* in his *Curæ poſteriores folio* 59. *Viola montana pumila*: the third by him in his hiſtory *Viola montana laciniata*: the fourth and fift have not beene remembred by any before: the two laſt are reckoned under the generall name of *Viola tricolor* with the addition of *ſylveſtris* to ſhew their diſtinctions.

The Vertues.

The Garden Violets and ſo likewiſe the wilde kindes are cold and moiſt while they are freſh and greene, and are uſed to coole any heate or diſtemperature of the body, eyther inwardly or outwardly, the inflammations in the eyes in the mother or in the fundament when they are fallen downe & are full of paine, Impoſtumes alſo and hot ſwellings, to drinke the decoction of the leaves or flowers made with water or wine, or to apply them poultis wiſe to the grieved place, it likewiſe eaſeth paines in the head, which are cauſed through want of ſleepe, or in any other place ariſing of heate applyed in the like manner, or with oyle of Roſes: a dram weight of the dryed leaves of the flowers of Violets, (but the leaves more ſtrongly) doth purge the body of chollerick humors, and aſſwageth the heate being taken in a draught of wine or any other drinke: the powder of the purple leaves of the flowers onely pickt and dryed, and drunke in powder with water is ſaid to helpe the Quinſie and the Falling ſickneſſe in children, eſpecially in the beginning of the diſeaſe: the flowers of the white Violets ripeneth and diſſolveth ſwellings: the ſeede being taken reſiſteth the force of the Scorpion: the herbe or flowers while they are freſh, or the flowers when they are dry are effectuall in the Pluriſie and all other diſeaſes of the Lungs, to lenifie the ſharpeneſſe of hot rheumes and the hoarſeneſſe of the throate, the heate alſo and ſharpeneſſe of urine, and all paines of the backe or reynes and the bladder: it is good alſo for the Liver and the Iaundies, and in all hot Agues helping to coole the heate, and quench thirſt: but the Syrupe of Violets is of moſt uſe and of better effect being taken in ſome convenient liquor, and if a little of the juice or Syrupe of Lemons bee put to it or a few drops of the oyle of Vitrioll, it is made thereby the more powerfull to coole the heate and to quench the thirſt, and beſides the effect giveth to the drinke a Claret wine colour and a fine tart relliſh pleaſing to the taſte. Violets taken or made up with hony doth more clenſe then coole, and with Sugar contrariwiſe: the dryed flowers of Violets are accounted among the Cordiall flowers and are uſed in cordialls, drinkes powders and other medicines, eſpecially where cooling cordialls, as Roſes and Saunders are uſed: the greene leaves are alwayes uſed with other herbes to make Cataplaſmes and Poultiſes for inflammations or ſwellings, and to eaſe paines whereſoever ariſing of heate and for the piles alſo being fryed with Yolkes of Egges and applyed thereto. Panſyes or Hearts eaſe is like unto Violets in all the parts thereof, but ſomewhat hotter and dryer, yet very temperate, and by the viſcous or glutinous juice therein doth ſomewhat mollifie, yet leſſe then Mallowes: it is conducing in like manner as Violets to the hot diſeaſes of the lungs and cheſts, for agues, for convulſions, and the falling ſickneſſe in children: the places alſo troubled with the itch or ſcabs being bathed with the decoction of them doth helpe much: it is ſaid alſo to ſoder greene wounds, and to helpe old ſores to uſe the juyce or the diſtilled water: *Lugdunenſis* ſetteth it downe that many ſacks full of the flowers and herbes are tranſported from *Marſeilles* in *France* unto *Alexandria*; and other parts of *Egypt* where they uſe them boyled in water, which onely by their religion they are enjoyned to drinke, not onely thereby to make it the more wholeſome to be drunke: but are perſwaded alſo that it helpeth the diſeaſes of the lungs and cheſt, and the falling ſickneſſes.

CHAP. XVI.

Fragaria. Strawberries.

IN my former Booke I have ſhewed you not onely moſt of the edible Strawberries, but one wild ſort alſo that was fit to furniſh that Worke, the figure of one which will decipher all the reſt I give you here; there are ſome other ſorts to be entreated of fit to be eaten, which were omitted, and others that are wilde without edible fruit, and therefore called by ſome barren or without fruite.

1. *Fragaria minor hiſpido folio*, Small Strawberries with hard leaves.

This Strawberrie groweth like to other Strawberries both in leaves, flowers, and fruite, but leſſe in all of them; and to diſtinguiſh it the more certainely from the other ſorts, the leaves hereof are hard rough and hairie, grayiſh as well on the upper as underſide: the berries when they are ripe are ſmall but ſufficient pleaſant to eate, red on the one ſide, and white on the other, as if they were equally divided.

2. *Fragaria Alpina fructu compreſſo.* Flat Strawberries.

There is no difference in this kinde from our ordinary Strawberrie, but in the fruit which is more flat than round, and hath a ſtrake or liſt, every berrie of a taſte neare a Raſpis: this alſo uſually beareth fruit againe in the *Autumne*.

3. *Fragaria Helvetia nana.* Dwarfe Strawberries.

Divers may judge that this Strawberriee ſmallneſſe commeth by the barrenneſſe of the ſoyle wherein it groweth, but that is not ſo: for it is well knowne to moſt, that thoſe hills of the *Swiſſers* have no barren ground upon them: this hath very ſmall triparted leaves next the ground, cloſer ſet together upon ſhort foote ſtalkes than any other, and thoſe that are ſet on both ſides of the long branch, not above foure inches long, which lieth creeping on the ground, grow leſſe and without ſtalke: the flower ſtandeth at the end of the branch many times, but one at a place, which conſiſteth of five round leaves like a Strawberrie, but larger then agreeth with the proportion of the plant, and is of a yellowiſh colour; what fruite this beareth wee have not yet ſeene or knowne certainely. This commeth neare unto the deſcription of the *Fragariæ affinis ſericea planta* of *Bauhinus*, his brother formerly ſo calling it, which as he ſaith is the *Leucas Dioſcoridis Adverſariorum*, and giveth thereunto a ſmall head containing ſmall ſeede therein: but this was brought us from the *Alpes* by one *Fleſcher* a *Sileſian*, a young Doctor in Phyſicke but very skilfull in ſimples, who periſhed in *Virginia* by taſting ſome

poy ſonfull herbe, and therefore I thinke it ſhould beare a Strawberrie like head, whereunto I am the rather perſwaded, becauſe that as *Bauhinus* citeth, although wrongfully, as I thinke, for I cannot finde it in him. *Geſner in hortis* that he ſhould call one *Fragaria parva flore luteo*: the rootes are blacke and ſtringie.

Fragaria vulgaris. Common Strawberries.

4. *Fragaria minime veſca.*

Barren or unprofitable Strawberries.

This Strawberrie is in the growing altogether like the ordinary kindes, with leaves triparted ſtanding on ſeverall ſtalkes and flowers, in the ſame manner but ſmaller, the fruite onely maketh the difference betwixt them, which being ſmall and many ſet together, are ſere and drie without ſappe and of an harſh unpleaſant taſte.

The Place.

The three firſt plants grow upon divers of the *Alpes*, and other places of *Germany*, and the laſt in our owne Land in moſt woods and the fields ſides neare unto them, in *Cornewall*, as *Lobel* ſaith, but in other places alſo.

The Time.

They flower in *May*, when the other ſorts doe for the moſt part or ſomewhat later, and the fruite is ripe quickly after.

The Names.

The whole plant is called in Latine *Fragaria*, and the berries *Fraga a fructus fragrantia odoris & guſtus*, for it hath no certaine Greeke name that I know, unleſſe as *Tragus* thinketh it may be referred to the πεῖφυλλον of *Dioſcorides*, or as others thinke to the χύμαεγν *Comaron* of *Apuleius*, but neither of them is likely: others ſuppoſe that *Dioſcorides* did underſtand this plant under his πενταφύλλα: ſome have called it *Rubus Idæus non ſpinoſus*, but there is a ſhrubbe like unto the Raſpis that beareth no thornes, as I have ſhewed in my former Booke. *Pliny* maketh mention of *Fraga*, *lib.* 25. *c.* 9. *Servius* calleth them *Mora terreſtria*, and therefore ſome would referre it to the *Chamæbatus*: the *Italians* call the plant *Fragheria*, and the berries *Fraghe* and *Fragole*; the *French Fraiſier* and *Fraiſes*, the *Germans* call the fruit *Erdbeer*, and the *Dutch Erdtbeſien*, and we in *Engliſh* Strawberries. The firſt here ſet forth is the third *Fragaria* of *Tragus*, which he ſaith the people about *Spires* in *Germany* doe call *Harbeer*; and *Geſner in hortis Germaniæ* calleth *Fragariæ ſpecies minor*: the ſecond is called by *Cæſalpinus Fragariæ genus in Alpibus*; and *Bauhinus Fragaria bis fructum gerens*: the third is likely to be the *Fragaria flore luteo* of *Bauhinus* who citeth *Geſner in hortis*, as I ſaid in the deſcription, to call it ſo; and I thinke it may as well agree unto the *Leucas* of *Lobel* which *Bauhinus* ſeemeth to make another plant differing therefrom, calling it *Fragariæ affinis ſericea incana*, for the deſcriptions are very correſpondent: the laſt is that which *Lobel* calleth *Fragaria ſylveſtris minimæ veſcæ ſive ſterilis*, but is not that which *Gerard* calleth *Fragaria veſca ſive ſterilis*, which is another plant, as I have ſhewed before.

3. *Fragaria Helvetica nana.* Dwarfe Strawberries.

The Vertues.

Theſe Strawberries that are here ſet forth and fit to be eaten, are of the ſame qualitie with the other garden kinds expreſſed in my former Booke, the leaves of them all being cooling in the firſt degree, and yet ſome ſay hot and drying in the ſecond, the roote is more drying and binding, the berries while they are greene are cold and drie, but when they are ripe they are cold and moiſt: the berries are excellent good to coole the liver, the bloud and ſpleene, or an hot chollericke ſtomacke to refreſh and comfort the fainting ſpirits, and to quench thirſt: they are good alſo for other inflammations, yet it behoveth one to be cautelous, or rather to reſtraine them in a fever leaſt by their putrefying in the ſtomacke, they encreaſe the fits and cauſe them to be the more fierce: the leaves and rootes boiled in wine and water and drunke, doe likewiſe coole the liver and bloud, and aſſwage all inflammations in the raines and bladder, provoketh urine, and allaieth the heate and ſharpeneſſe thereof: the ſame alſo being drunke ſtaieth the bloudy flixe and womens courſes, and helpeth the ſwellings of the ſpleene: the water of the berries carefully diſtilled, is a ſoveraigne remedy and cordiall in the palpitations of the heart, that is, the panting and beating of the heart, and is good for the overflowing of the gall, the yellow jaundiſe; the juyce dropped into foule ulcers, or they waſhed therewith or with the decoction of the herbe and roote, doth wonderfully clenſe them and helpe to cure them. All lotions and gargles that are made for ſore mouthes or ulcers therein, or in the privie parts, or elſe where are made with the leaves and rootes hereof, which is good alſo to faſten looſe teeth, and to heale ſpungie foule gummes: the ſame alſo helpeth to ſtay catarrhes or defluxions of rheume into the mouth, throate, teeth or eyes: the juyce or water is ſinguler good for hot and red inflamed eyes, if ſome thereof be dropped into them, or they bathed therewith, the ſaid juyce or water is alſo of excellent propertie for all puſhes, wheales, and other eruptions of hot and ſharpe humours into the face or hands, or other parts of the body to bath them therewith, and helpeth to take away any redneſſe in the face, and ſpots or other deformities of the skinne, and to make the skin

cleare

cleare and ſmooth: ſome uſe thereof to make a water for hot inflammations in the eyes, and to take away any filme or skin that beginneth to grow over them, or other defects in them that any outward medicine can helpe in this manner: Take what quantitie of Strawberries you pleaſe, and put them into a braſſe veſſell, with a little ſalt caſt upon them, which being covered, ſet into a wine cellar for eight dayes, in which time the berries will be diſſolved into a greene water, which being cleared from the reſt, keepe in a glaſſe cloſe ſtopped to uſe when you neede: a droppe or two put into the eyes ſerveth for the purpoſe aforeſaid: ſome in miſliking both ſalt and braſſe for the eyes, make a water both for the eyes and for the deformities in the skinne, be it morphew, leprey, or the like in this manner: Into a large deſtillatory or body of glaſſe, they put ſo many Strawberries as they thinke meete for their uſe, if a few, the leſſer glaſſe body will ſerve, which being well cloſed, let it be ſet in a bed of hot horſe dung for twelve or fourteene dayes, and after diſtilled carefully and the water kept for your uſe.

CHAP. XVII.

Alſine. Chickweede.

THere are ſo many ſorts of Chickweedes, ſome chiefely growing in moiſt and watery places, others upon drie mountaines, ſome in the Fields, others in the Woods, ſome worthy of ones paines to plant in a Garden, others of no ſuch reſpect that I muſt ſeverre them, and intreate of ſome in an other Claſſis where they are fitteſt to be ſpoken of; you ſhall therefore have thoſe evpreſſed in this Chapter, and the two next that follow that I thinke fiit for this place.

1. *Alſine repens baccifera.* Great ſpreading Chickweede.

This great Chickweede bringth forth many flexible branches full of joynts, riſing higher than a man if it ſtand by buſhes, or other things where it may take hold, otherwiſe through weakeneſſe lying on the ground, it ſeemeth not ſo long, at every of the joynts ſtand two leaves one againſt the other, ſomewhat like unto the ordinary Chickweede leaves, but much larger, comming ſomewhat neare unto thoſe of Pelletory of the wall, and of a freſh greene colour: at the joynts likewiſe on both ſides of the ſtalkes come forth other branches, joynted and ſet with leaves in the ſame manner, and at the ends of them large greene round huskes ending in five points, with whole flowers growing out of them, conſiſting of five and ſometimes of ſixe white leaves apeece cut in at the ends, in which huskes after the flowers are paſt ſtand ſmall round heads like berries, greene at the firſt, and blackiſh when they are ripe, containing within them many flat blackiſh purple ſeed: the roote is white and long creeping much under ground, and ſhooting forth in divers places every yeare new ſhootes, the old dying downe every yeare: this hath no taſte, but herbye as the ordinary Chickweedes have, and therefore is by the judgement

1. *Alſine repens baccifera.*
Great ſpreading Chickweede.

2. *Alſine maxima.*
The greateſt Chickweede.

of the beſt Herbariſts referred unto them, yet *Lugdunenſis* ſaith it hath a ſtinking and moſt unpleaſant taſte.

2. *Alſine maxima.* The greateſt Chickweede.

This Chickweede which is the greateſt of all the ordinary ſorts riſeth up with ſundry ſtalkes, a foote high or more, and lye not on the ground as the ſmaller ſorts doe, bearing two leaves uſually at a joynt larger then in any other that follow, but ſomewhat narrower then the former, it beareth plenty of white flowers, of ſix leaves a peece; ſtanding in long greene huskes, which containe likewiſe the head or ſeede veſſell, after the flowers are fallen, with ſmall yellowiſh ſeede in them; the roote is white and threddy like the reſt.

Alſine minor. The ſmaller Chickweede.

3. *Alſine major.* Great Chickweede.

This great Chickweede is in all things like thē laſt both in leafe and flower, but ſmaller, the ſtalkes ſtand not fully upright but doe a little bend downewards, and needeth no other deſcription to cauſe it to bee knowne. There is another ſort hereof differing in nothing elſe but the ſmalneſſe of the whole plant. *Minor.*

4. *Alſine Bætica. Spaniſh* Chickweede.

The *Spaniſh* Chickweede riſeth up very often with a ſingle upright reddiſh ſtalke, not branched at all, and ſometimes with many, about a foote or more high, full of joynts, at each whereof grow two ſmooth and darke greene leaves, narrower then the laſt, a little broader at the bottome next the ſtalke, and ſmall pointed at the ends, the middle ribbe on the backſide being ſomewhat great and raiſed up: the flowers ſtand at the end of the ſtalke many ſet together in heads or huskes like thoſe of *Symphytum petræum*, of a purpliſh colour; the roote is ſmall white and long.

5. *Alſine recta triphyllos ſive laciniata.*

Vpright Chickweede with jagged leaves.

This jagged Chickweede groweth upright, with a ſtalke for the moſt part branched into three or foure ſmaller ſprayes about a foote high, ſet at the ſeverall joynts, with ſmall long leaves, cut into three and ſometimes foure parts, even to the middle ribbe almoſt, ſo that they ſeeme like ſeverall leaves ſpread like ſo many fingers to the hand: thē flowers come forth at the toppes and uppermoſt joynts, conſiſting of five ſmall blew and round pointed leaves, with ſome threds in the middle, and ſtanding in ſmall greeniſh huskes, wherein after the flowers are withered and gone, appeare ſmall flat heads divided as it were into two parts, wherein lye ſmall whitiſh ſeede: the roote is ſmall and long, ſet with many fibres and periſheth every yeare after ſeedetime, and ſpringeth againe of the ſeede that is ſhed.

The Place.

The firſt as *Cluſius* ſaith groweth in divers places of *Spaine* and *Germany* alſo, and I have ſometimes found it by hedge ſides in our own Land: the ſecond and third is uſually found in moyſt and watery places, by wood ſides alſo oftentimes and in many other places, the fourth *Cluſius* found in *Spaine*: the laſt groweth in ſundry grounds and among rubbiſh ſometimes.

The Time

They flower about *Iune*, and their ſeede is ripe in *Iuly*.

The Names.

Chickweede is called in Greeke ἄλσινη *quod lucos, quos* ἄλσεα *nominant, & umbroſa loca amat*, and *Alſine* alſo in Latine, *Dioſcorides* and from him *Pliny*, *lib.* 27. *cap* 4. ſaith *Alſine quam quidam Myoſotin appellant naſcitur in lucis unde & Alſine dicta.* The firſt is called by *Cluſius Alſine repens*, and ſo it is alſo by *Camerarius* and *Dodonæus*, *Lobel* calleth it *Planta Alſines majoris facie baccis Solani Cacubalum Plinij*, but ſome would make the *Solanum hortenſe* to be *Cacubalum*, led by the falſe coppie of *Dioſcorides*, which hath divers names to herbes which is generally reported to be none of his worke, becauſe the confuſion of names taketh away the knowledge of the true one, *Lobel* in *Adverſarijs* calleth it *Alſines majoris facie planta baccis Solani*, and maketh a doubt whether it bee *Cacubalum Plinij quaſi maleficum*. *Lugdunenſis* alſo calleth it *Cacubalus Plinij ſive Ocimoides repens*, *Lucas Ghinus* taketh it to be *Cyclaminus altera*, but *Pena* and *Lobel* ſay that therein hee ſheweth himſelfe not well exerciſed in plants, *Bauhinus* calleth it *Alſine ſcandens baccifera*, the generall name among Herbariſts is *Alſine baccifera*; for although the ſecond which is the greateſt Chickweede next unto it beareth heads of ſeede ſomewhat like it, yet they are nothing ſo great nor the ſeede within them, and is the *Alſine maxima* of *Lugdunenſis*, which *Bauhinus* calleth *Anguſtifolia*: the third is the *Alſine maior* of *Lobel*, the ſecond *Morſus gallinæ* of *Tragus*, the *Alſine major* of *Camerarius*, *Dodonæus*, *Lugdunenſis* and others, and is called by *Cæſalpinus Centunculus viticulus cubitalibus*, and *Bauhinus altiſſima nemorum*: the fourth is the *Alſine alia* and *Bætica* of *Cluſius*, which *Bauhinus* calleth *Alſine Symphyti petræi capitulis*: the laſt is called by *Lobel* and *Camerarius Alſine parva recta*, *Tragus* not knowing to what herb he might referre it, diviſeth a name according to the forme of the fingers of ones hand as he took it to be like, & calleth it in his own language *Handlekrant cæruleis floribus* (for this other of that kind with a white flower is the *Paronychia rutaceo folio Lobelij*) and thereupon giveth it the name of *Dactylobotanon cæruleo flore*, *Lugdunenſis* maketh it to be an *Elatine* and calleth it *Elatine triphyllos*, and *Columna* as I take it meaneth this plant which hee calleth *Alſine tenuifolia altera ſive terreſtris altera tricephyllon*, but not *Lagina ſpergula* as *Bauhinus* ſaith, for as all agree

agree, the leaves hereof are divided but into three parts, and the *Sagina Spergula* into ſix as *Columna* in the ſame place doth acknowledge, beſides, theſe are ſet but as ſingle leaves divided at the ends, and the *Sagina* of many leaves ſet like the Rowell of a Spurre, *Bauhinus* calleth it *Alſine triphyllos cærulea.*

The Vertues.

The ſecond and third great Chickweedes arē of moſt uſe, for the other of theſe ſorts are not applyed to any uſe that I can learne, *Lobel* ſaith that ſome did affirme that the *Cacubalum* is no leſſe deadly to be eaten then the ſleepie Nightſhade; yet if the firſt be the *Cacubalis* or *Cacubalum* of *Pliny* hee ſaith otherwiſe, for hee ſaith that the leaves thereof bruiſed with ſome Vinegar and applyed to the place ſtung with Serpents or Scorpions helpeth them, and that the juice thereof taken with twice ſo much ſweete or honyed wine, eaſeth the paines of the backe and loynes, and the paines of the head or headach if it be applyed with Roſewater to the forehead and temples, and that being bound to Wens or Kernells or elſe they bathed therewith diſſolveth them. The other great Chickweedes are of as good uſe as any of the ſmaller ſorts, and are good to coole any inflamation and is aſtringent withall as *Dioſcorides* ſaith, but *Galen* and *Oribaſius* ſay they have no aſtringent quality in them, *Paulus Ægineta* and *Ætius* agree in the cooling, but ſay nothing of the binding propertie, it ſerveth therefore for all manner of heate whether inward or outward, to coole and temper the blood inflamed in Agues, or the heate of the ſtomacke and liver breaking out into the lippes, and to procure an appetite being loſt or become weake, and is uſed in Hecticke feavers, and to aſſwage the heate of the backe and urine. *Galen* and other ſay that it hath the ſame vertues that Pelletory of the Wall hath, but wee have commonly found it to bee as effectuall as Purſlaine to all the purpoſes whereunto it ſerveth except for meat onely: the herbe bruiſed or the juice applyed with clothes or ſpunges dipped therein to the region of the Liver, and as they drye to have freſh applyed doth wonderfully temper the heate of the Liver, the ſame likewiſe is effectuall for all hot Impoſtumes and ſwellings whereſoever, Saint *Anthonies* fire and the like, and for all redneſſe in the face, Wheales, Puſhes, Itches or Scabs, eyther the juice ſimply uſed or boyled with *Axungia* and applyed: the ſame is ſaid to helpe Crampes, Convulſions and Palſies, applyed in the ſame manner: the juice or the diſtilled water is of much good uſe for all heate and redneſſe in the eyes to drop ſome thereof into them, as alſo into the eares to eaſe paines in them, and is of good effect to eaſe the paines heate and ſharpeneſſe of the blood in the piles, and generally for all paines in the body that riſe of heate, it is uſed alſo in hot and virulent Vlcers and ſores in the privie parts of man or woman, or legs or elſe where, the leaves boyled with Marſh Mallowes and made into a Poultis with Fenigreck and Linſeede, applyed to ſwellings or Impoſtumes ripeneth and breaketh them, or ſwageth the ſwellings, and eaſeth the paines; the ſame alſo helpeth the Sinewes when they are ſhrunke by Crampes or otherwiſe, and to extend them and make them plyable againe: it is ſayd by ſome that while the hearbe is in boyling with Oyle or *Axungia* to make a ſalve fit to heale ſore Legs, that if one doe ſtirre it with their bare finger they ſhall take no harme thereby, if any will make it *probatum* they may make it a meritorious worke: when a Sinew is ſtrayned here is a faire medicine for it: Boyle a handfull of Chickweede, and an handfull of red Roſe leaves dryed but not diſtilled, in a quart of Muſcadine untill a fourth part be conſumed, then put to them a pint of the Oyle of Trotters or Sheepes feete, let them boyle a good while ſtill ſtirring them well, which being ſtrayned annoint the greeved place herewith warme againſt a fire, rubbing it well in with ones hand; and binde alſo ſome of the herbe if ye will to the place, doe ſo againe the next morning and evening, by which time you ſhall finde helpe if God will.

CHAP. XVIII.

Alſine Montana. Mountaine Chickweede.

ANother ſort of Chickweede groweth upon hills moſt uſually, whereof ſome are greater, and others ſmaller, of whom in this Chapter and firſt of the greater.

1. *Alſine montana hederacea maxima Columnæ.* *Columna* his great Ivie leafed Chickweede.

This great Chickweede groweth up with upright ſtalkes, yet ſomewhat bowing downe againe with the lower branches ſet at each joynt with two ſomewhat large leaves, waved about the edges, and as it were crumpled and hairy, ſomewhat like unto the curld Mallow, being two inches broad and three long, reſembling long Ivie leaves or great Bindeweede rather, ſtanding upon long foote ſtalkes: the flowers ſtand at the ends of the branches, conſiſting of five white leaves, ſo deepely cut in at the middle that they ſeeme to be ten, riſing out of the greene huskes, wherein after the flowers are paſt groweth a long round ſeede veſſell cornered or creſted with a ſmall ſpire top, ending in a ſmall pricke, wherein lye ſtore of ſmall ſeede; the roote conſiſteth of ſome long ſtrings with fibres ſet at them.

2. *Alſine Hederulæ folio major Lobelij.* *Lobel* his greater ground Ivie leafed Chickweede.

The greater ground Ivie leafed Chickweede hath ſundry almoſt round leaves next the ground, dented or cut in on the edges, making them ſeeme ſomewhat like Ale-hoofe or ground Ivie leaves of a ſullen greene colour, and ſomewhat hairy as the ſtalkes are, which have at every joynt ſuch a round dented leafe as growbelow, but compaſſing it without any footeſtalkes, whereat eſpecially from the middle upwards come forth ſmall hooded gaping blew flowers, ſomewhat like unto thoſe of Germander, the ſeede is ſmall and the roote ſtringy periſhing yearely.

3. *Alſine hederulæ folio minor.* The ſmaller ground Ivie leafed Chickweede.

The other Ivie leafed Chickweede groweth lower and more leaning to the ground with the branches, which are ſomewhat hairy alſo and more tender, ſet with two leaves at a joynt, but nothing ſo large: the flowers grow at the toppes conſiſting of five ſmall blew round pointed leaves, the ſeede is ſmall contained in round heads: the roote is ſmall and threddy.

4. *Alſine foliis ſubrotundis Veronicæ.* Speedewell Chickweede.

This ſpreadeth many ſmall branches upon the ground full of ſmall and almoſt round leaves, ſet by couples very like to thoſe of *Veronica* or *Betonica Pauli*, called Speedewell, but not unto *Elatine* or *Fluellen* of any ſort: the flowers grow at the joynts with the leaves from the middle of the branches upwards, being very ſmall, made of

1. *Alsine montana hederacea maxima.*
Great Ivie leafed Chickweede.

2. *Alsine hederulæ folio major.*
The greater ground Ivie leafed Chickweede.

3. *Alsine folio hederulæ minor.*
The lesser ground Ivie leafed Chickweede.

4. *Alsine foliis subrotundis Veronicæ.*
Speedewell Chickweede.

five blew leaves, after which come ſmall flat ſeede veſſells like pouches, wherein is conteined ſmall round yellowiſh ſeede: the roote is ſmall and threddy, and periſheth not in Winter.

5. *Alſine montana capillaceo folio.* Small narrow leafed Chickweede.

This ſmall Chickweed hath divers ſmal branches but riſing a little above the ground, with ſmal ſomewhat long and narrow ſmooth whitiſh leaves, ſet by couples at the joynts, from betweene which riſe ſmaller branches, with the like leaves on them, and at their ends two or three ſmall white flowers made of foure leaves a peece, the ſeede that followeth is ſmall and browne conteined in round heads: the roote is ſmall and threddy.

6. *Alſine repens anguſtifolia flore ſuave-rubente.* Bluſh narrow leafed Chickweede.

This Chickweede creepeth with the branches upon the ground, bearing ſuch like ſmall long and whitiſh leaves, ſet by couples as in the laſt, but both branches and leaves are bigger then they: the flowers grow at the ends of the branches of a bluſh colour, which give long and pointed ſeede veſſels, wherein is contained ſmall ſeede like the common Chickweede.

7. *Alſine Petræa.* Rockie Chickweede.

This is a ſmall Chickweede but groweth ſo full of ſmall upright branches thicke ſet, and enterlaced one within another, that it ſeemeth like unto a ſmall buſh, the leaves are ſmall and pointed, and the flowers ſmall and white like other ſmall Chickweedes, bearing round heads like unto Line or Flax, wherein the ſmall ſeede is contained: the roote is ſmall and threddy.

8. *Alſine Alpina glabra.* Smooth leafed mountaine Chickweede.

This Mountaine Chickweede is like unto the other ſmall Chickweedes, riſing up with the branches ſcarſe halfe a foote high, ſet with ſmall long and ſmooth leaves like thoſe of Line or Flax, of a pale greene colour, but ſhorter and ſharpe pointed, the flowers are white, Starre faſhion like others ſtanding upon ſmall long footeſtalkes: the heads and ſeede are like the reſt and ſo is the ſmall fibrous roote.

9. *Alſine Alpina minima glabra.* The ſmalleſt mountaine Chickweede.

This other mountaine Chickweede is ſmaller then the laſt, but more beautifull in regard of the flowers which are made of foure leaves a peece, either white or whitiſh, ſpotted with ſmall prickes or ſpots of a deeper red colour ſtanding three or foure together, each ſeverally upon a ſmall footeſtalke and they all upon ſmall branches ſcarſe foure inches long ſet with the like pale greene narrow leaves, yet bare toward the toppes neare unto the flowers.

10. *Alſine Alpina Iunceo folio.* Ruſh leafed mountaine Chickweede.

The Ruſh leafed Chickweede groweth little above an handbreadth high, ſpreading from the ſtalke a couple of branches which are divided againe into ſmaller, whereof ſome onely and not all doe beare a flower or two at the end, ſomewhat large for the proportion of the plant, made of five white leaves ſtanding in ſmall greene cups, the leaves on the branches are very narrow, ſmall, and very greene, hard alſo in handling, and ſet without order.

11. *Alſine nodoſa Gallica.* *French* Chickweede with knotted heads of ſeede.

This ſmall Chickweede groweth ſometimes a foote high, having many long and narrow leaves lying next the ground, from whence riſe divers upright ſtalkes ſet with ſmaller leaves without order, from the middle upwards one above another: at the joynts ſtandeth one ſmall white flower a peece, compoſed of five white leaves, after which come ſmall heads of ſeede ſtanding one above another, as if they had beene ſtrung upon a ſtring, and ſomewhat creſted or furrowed: the roote is ſmall and full of fibres of a yellowiſh colour on the outſide.

The Place.

All theſe ſorts of Chickweedes grow upon hills and mountaines in divers places, ſome in *Italy*, *Spaine* and *France*, *&c.* and many of them in our owne Land:

The Time.

They doe all flower in *Iune* and *Iuly* except the ſixt, which flowreth not untill *Autumne*.

The Names.

The firſt is ſo called by *Columna* as it is in the title, who ſaith it was not mentioned by any before him: the ſecond is the *Alſine folio Hederulæ altera* of *Lobel*, the third is called by *Lugdunenſis* and *Thalius Elatine prior*, by *Dodonæus Alſine ſpuria prior*, by *Camerarius Alſine hirſuta*, by *Lobel Morſus gallinæ folio hederulæ*, thought to be *Hippago Plinij* by *Anguilara*, and called *Centunculus hirſutior* by *Cæſalpinus*; but generally *Alſine hederacea*, and *hederulæ folio*, *& minor* I have added to diſtinguiſh it from the greater: the reſt have their denominations by *Bauhinus* as they are ſet downe in their titles.

The Vertues.

All theſe herbes being but lately found out and to be referred to the family of Chickweeds, are not of ſuch experienced uſe, as theſe of an ancienter knowledge: but it is moſt probable that being in taſte ſomewhat agreeing unto the common ſort, their qualities are not much differing, and therefore untill wee have learned ſome certaine properties whereunto they are effectuall, let this be ſufficient at this time to have given you the knowledge of their being.

CHAP. XIX.

Alsines spuriæ aliæ parvæ. Small Baſtard Chickweedes.

THere are ſome other Chickweedes to be entreated of that pertaine to this Claſſis, and grow in ſeverall ſoyles which ſhall be ſhewed in this Chapter.

1. *Alsine Viſcoſa.* Clammy Chickweede.

This clammy Chickweede ſtandeth more upright then the laſt, with rough, hairy and clammy leaves ſomewhat like the other, but of a more blewiſh greene colour: the flowers hereof are white and ſmall, ſcarce opening themſelves but in the hot time of the day, ſtanding at the toppes of the ſtalkes, which from the middle upwards are ſo clammy, that they will ſticke to the fingers of any that touch them, whereby they are apt to hold flyes, and ſuch other ſmall things as light upon them.

2. *Alsine Muſcoſa.* Moſſe like Chickweede.

This creeping and ſpreading Chickweede ſcarce ſheweth it ſelfe above the Moſſe and other herbes among which it groweth, with very ſlender ſmall ſtalkes and ſmall fine but thicke leaves thereon, and ſmall white flowers of foure leaves a peece at the ends turning into long and round heads like unto the other ſmall Chickweedes, the rootes are nothing but threads.

3. *Alsine nodoſa Germanica.* Knotted Chickweede of *Germany*.

This knotted or great joynted Chickweede, thereof tooke the name becauſe the ſtalkes which are part leaning and part upright an handbreadth long, have the joynts more knotted or bunched out then then in others, the greene leaves that grow at them are very ſmall and long like threads, many ſet together, from whence likewiſe ſpread ſmall branches bearing ſmall white flowers of five leaves, ſet in great huskes that end in five corners every one on a long footeſtalke.

4. *Alsine folio Triſſaginis.* Germander leafed Chickweede.

This ſmall Chickweede ſpreadeth ſundry ſmall weake branches upon the ground, three or foure inches long, ſet with ſmall ſomewhat round leaves dented about the edges, and pointed at the ends, by couples one againſt another, at the joynts whereof towards the toppes come forth ſmall blew flowers, and ſometimes white, conſiſting of five round pointed leaves, after which ſucceede ſmall round ſeede veſſells, two alwayes joyned together, having ſmall round ſeede within them; the roote is compoſed of many threds, and abideth the Winter.

5. *Alsine corniculata Cluſii.* *Cluſius* his horned Chickweede.

This Chickweede riſeth up a ſpanne high, with one tender hairy ſtalke full of joynts, and two ſmall long ſomewhat hairy leaves ſet at them, towards the toppe divided into ſome branches, where and at the joynts alſo come forth ſmall white flowers in greene huskes, and after them ſmall and long thinne tranſparant hornes, as it were like to Cockes ſpurres, and clammy withall, wherein lye ſmall blacke ſeede: the roote is ſmall and annuall.

4. *Alsine folio Triſſaginis.*
Germander leaſed Chickweede.

5. *Alsine corniculata Cluſij.*
Cluſius his horned Chickweede.

The

The Place.

These Chickweedes grow in Fields as well tilled as untilled, and by the wayes sides, &c.

The Time.

They flower in Sommer, some a little earlier or later than others, and their seede is ripe quickly after.

The Names.

The first *Bauhinus* calleth *Alsine hirsuta altera viscosa*, and *Camerarius Alsine viscaria*, *Dodonæus Alsine spuria quarta*, and *Gesner in collatione stirpium Alsine species glutinosa*, yet this is not the *Lychinis viscosa* or any sort thereof, although for the properie it might be called *Muscaria*: the second *Lugdunensis* calleth *Alsine muscosa*: the third is called by *Bauhinus Alsine nodosa Germanica*, and differeth from the *nodosa Gallica*, whose heads of seedes are like knottes upon a thread or string, as is shewed in the Chapter before: the fourth is the third *Morsus Gallinæ* of *Tragus*, the *Alsine spuria altera* of *Dodonæus*, called by *Lobel* and others *Alsine folio Trissaginis*, taken to be *Antirrhinon Dioscoridis* by *Cæsalpinus*, and by *Bauhinus Asine Chamædrifolia floseulis pediculis oblongis insidentibus*: but surely if ever he saw any whose flowers had long stalkes, I did never: the last is so called, first by *Clusius*, and after him by all others, as it is in the title, yet some supposed it might be a kind of *Nigellastrum* or Cockle.

The Vertues.

There is little use in Physicke of these Chickweedes, yet the two first are of the taste of Burrage, and the rest of Chickweede.

CHAP. XX.

Borrago & Buglossum. Borrage and Bugloss.

ALthough I have given you in my former Booke the knowledge of the Garden Borrage and Bugloss, and some other sorts of them, yet there doe remaine some others both of the Garden and wilde kindes, whereof I meane now to speake.

1. *Buglossum minus sativum.* Small Garden Bugloss.

This Garden Bugloss is very like the ordinary garden kinde for the manner of growth, but that it is smaller in all the parts thereof, the leaves are narrower and shorter, the flowers are smaller, some of a blew colour, and some purple; (and *Lobel* mentioneth one with a red flower, which he stileth *Echij facie Buglossum mininum flore rubente:*) the seede is likewise blacke but smaller: the roote perisheth not, and is like the other. *Buglossum Echij facie.*

2. *Buglossum sylvestre majus flore nigro.* Great wilde Bugloss.

This kinde of Bugloss differeth not from the last in any thing but in the greatnesse, being greater in every part, and in the colour of the flowers which are of so deepe a purple colour, that it is called blacke, and that it is found growing naturally in some places of *Italy*, and the other not but in Gardens.

3. *Blugloss sylvestre minus.* Small wilde Bugloss.

This other wilde Bugloss hath somewhat broad short and rough leaves, smaller than either the garden or the last wilde kinde, and somewhat more unevenly cut in on the edges: the flowers grow at the toppes of a blewish purple colour but smaller, and the seede groweth three or foure together like it, and blackish also: the roote is small and long.

Buglossum minimum Echij facie floribus rubentibus
Small Bugloss with red flowers.

4. *Blugloss sylvestre minus alterum,*
The rougher wilde Bugloss.

This rougher kind differeth from the last in these particulars: the leaves are much rougher than it, and sharper or smaller at the ends also: the flowers on the toppes of the branches are more like the flowers of *Galiopsis* Stincking dead Nettle than of any of the former sorts of Bugloss, some plants being of a blewish purple, colour and some white, and not of both these colours in one plant.

5. *Buglossum dulce ex Insulis Lancastriæ.*
Lancashire Bugloss.

Lancashire Bugloss shooteth forth many slender stalkes of a cubite high, some more, some lesse, the lower leaves whereof next the ground are much lesser than those of Borrage, and of a whiter greene, somewhat rough, but those that grow on the stalkes are lesser, having the flowers set at the joynts with them, whose buds before they are blowen are of a reddish colour, but when they are open, are of a blewish purple, somewhat like those of Vipers Bugloss, or betweene them and Borrage flowers, of a very sweete taste like hony, the roote groweth great and blackish on the outside, divided downewards into some great fanges.

6. *Borrago minor sylvestris.* Small wilde Borage.

This small Borage is very like the garden kinde, but that it is much smaller and slenderer, the leaves also are much smaller, narrower, shorter, rougher and more prickly, and of a paler greene colour, thinner set likewise upon the stalkes, for it hath but few branches: the flowers grow at the joynts with the leaves from the middle of the stalke upwards, three or foure set together, and are blew like the other, but more pale and roun-

der

1. *Bugloſſum minus ſativum.*
Small garden Bugloſſe.

2. *Bugloſſum ſylveſtre majus flore nigro,*
Great wilde Bugloſſe.

5. *Bugloſſum dulce ex Inſulis Lancaſtriæ.*
Lancaſhire Bugloſſe.

7. *Borago vltra herbariorum,*
Small creeping Borage.

der pointed, and ſo ſmall that they ſcarce ſhew themſelves out of the huskes wherein they ſtand or rather hang, for they turne downe their heads and quickly fall away; in the ſaid huskes are found foure ſmall flat ſeedes ſomewhat like unto *Echium*, or the wilde Bugloſſe: the roote is ſmall and long, and periſheth as ſoone as it hath borne ſeede which is very early.

7. *Borrago minor herbariorum.* Small creeping Borage.

This ſmall Borage ſhooteth forth many leaves from the roote very like unto the leaves of *Pulmonaria maculoſa*, ſpotted Cowſlips of *Ieruſalem*, every one upon a long foote ſtalke (but not ſpotted) of a darke greene colour, and leſſer than they: the ſtalkes are ſmall and ſlender not above halfe a foote high, with very few leaves thereon, and at the toppes come forth the flowers made of five blew round pointed leaves, more like Bugloſſe than Borage, without any threads in the middle, every one upon a long foote ſtalke, the roote is compoſed of many long blackiſh ſtrings more like unto *Avens* than Borage: in the leaves is a certaine acrimony or ſharpeneſſe, joyned with the muccilaginouſneſſe when they are taſted.

The Place.

The firſt is onely nurſed up in gardens, even in *Italy* from whence the ſeede was brought unto us and unto other countries alſo: the ſecond, third, and fourth grow wilde in divers countries, and are ſometimes found in our owne: the fift groweth in one of the Iles about *Lankaſhire*, there found by Mr. *Thomas Hesket*: the ſixt in *Germanie* as *Lobel* ſaith, and in *Naples* as *Columna* ſaith, and in our owne Land if I be not much deceived, for I thinke I have ſeene ſuch a one in divers fields in *Kent* as I have paſſed through them: the laſt *Lobel* ſaith he ſaw in the garden of the *Low countries* with thoſe that were lovers of rare plants, and proſpereth well in our owne gardens.

The Time.

They doe all flower in the moneth of *June* and *July*, yet *Lobel* ſaith that the laſt flowreth both in the Spring and in *Auguſt*, and their ſeede doth ripen quickly after, both ripe ſeede and flowers, may at one time be gathered from many of them.

The Names.

Our Garden Borrage is called by the Greekes, as *Pliny* ſaith, Εὐφρόσυνη *Euphroſine ab efficienda voluptate*; and by the judgement of the beſt of our moderne Writers is the true βουγλωσσον or βουγλωσσ& of the ancients, moſt truely imitating an oxe or neates tongue, which is *Lingua bubula* or *Bovino*, & ſo it ſeemed it was called by *Cato in, lib. de re ruſtica & c.* 40. when he adviſeth to take a leafe or a branch of *lingua bubula* to cover a ſtocke when it is grafted, to keepe away the raine from abiding in the cleft, for which purpoſe theſe leaves of Borrage being broader than thoſe of Bugloſſe is more fit. *Apuleius* ſaith, that *Bugloſſum* (meaning our Borrage) was called by them of *Luca*, *Corrago quod cordis affectibus medetur*, which by the alteration of one letter is *Borrago*, & from thence I think came the name of *Borrago*, which is not found in any of the ancient Writers. Our Bugloſſe is called by ſome *Bugloſſa* and *Bugloſſum* by moſt, yet ſome doe call it *Bugloſſum Hiſpanicum* and *Italicum*. Itwere an adviſe not to be contemned, that our Borrage ſhould be uſed for *Bugloſſum*, where it is appointed in any medicine, eſpecially in *Syrupo Byzantino*, for if the juyce of our Bugloſſe be taken to make it, the juyce is ſo ſlimie that it will never make a good ſyrrupe as it ought to be, unleſſe that after the bruſing of the herbe it be ſet in a celler or cold place before the juyce be preſſed. The firſt here expreſſed is called by *Fuchſius* and *Lonicerus*, and from them *Lugdunenſis Cirſium Germanicum*, for they did account all the ſorts of Bugloſſe to be *Cirſia* or *Echia*, as *Tragus* doth alſo, and calleth this *Bugloſſa minor*, *Fuchſius* likewiſe calleth it *Echium lanuginoſum primum*. *Geſner in hortis* calleth it *Bugloſſus minor*, and *Lugdunenſis Bugloſſum minus ſativum*. *Lobel*, as I ſaid in the deſcription, calleth that ſort with red flowers, which is a ſpecies hereof *Echij facie Bugloſſum minimum*, and thereupon *Bauhinus* calleth it *Bugolſſum anguſtifolium minus*: the ſecond *Matthiolus* calleth *Bugloſſum ſylveſtre* and *alteram flore nigro*; *Thalius Bugloſſa ſylveſtris nigra*, and *Bauhinus* thereupon *Bugloſſum ſylveſtre majus nigrum*: the third is called by *Dodonæus Bugloſſa ſylveſtris* and *fruticoſa*, and *Lycopſis ſylveſtris*; by *Lobel Bugloſſum erraticum aſperum Echioides*, by *Fuchſius Echium Germanicum ſpinoſum*, it is the *Borrago ſylveſtris* of *Tragus*, and called by *Bauhinus Bugloſſum ſylveſtre minus*: the fourth is called by *Tragus Bugloſſa ſylveſtris*, by *Lonicerus Lycopſis*, by *Cordus in hiſtoria Anchuſa minor*, by *Lugdunenſis Bugloſſum ſyveſtre minus*, and by *Bauhinus Bugloſſum ſyveſtre minus alterum*, and is likely to be the *Cynogloſſum* of *Tragus* and *Fuchſius*, for that it was formerly uſed among the *Germanes* for *Cynogloſſum*, and is called *Anchuſa altera* of *Cordus* upon *Dioſcorides*, the fift hath not beene related by any before: the ſixt is called by *Lobel Alyſſum Germanicum Echioides*, by *Thalius Bugloſſa ſylveſtris ſpecies*, and taken by *Tabermontanus*, and others to be the *Aparine major Plinij*: but *Cæſalpinus* calleth it *Crucialis quædam*, and *Dodonæus* in his *Dutch* Booke *Aſperugo ſpuria*; *Columna Borrago minor ſilveſtris*, and *Bauhinus Bugloſſum ſylveſtre caulibus procumbentibus*: the laſt is called by *Lobel Symphytum pumilum repens Borraginis facie*, *ſeu Borrago minima herbariorum*, which *Bauhinus* putteth among the *Symphyta*, and calleth it *Symphitum minus Borraginis facie*. The *Arabians* call the Borrage and Bugloſſe *Leſen arthaor*, the *Italians Boragine* and *Bugloſſa*, the *French Borache* and *Bugloſſe*, the *Germanes Buerres* and *Ochſenzunghe*, the *Dutch Bernage* and *Oſſentonghen*.

The Vertues.

Becauſe I was ſo brieſe in my former booke in ſetting downe the properties of the Garden Borrage and Bugloſſe, I thinke it convenient to expatiate their vertues under theſe wilde ſorts. The Garden kindesare temperate and accounted rather hot and moyſt in the firſt degree then cold, and yet for their cordiall porperties are often uſed among other cold herbes as conducing to the like effect. *Dioſcorides* appropriateth them with oyle againſt *Eriſypilas* or Saint *Anthonies* fire, and to cure greene wounds: The leaves or rootes are to very good purpoſe uſed in all putrid or peſtilentiall Feavers, to defend the heart, and to helpe to reſiſt and expell the poiſon or the venome of other creatures: the ſeede is of the like effect and alſo helpeth Nurſes to have more ſtore of milke, for which purpoſe the leaves are much conducing: the leaves, flowers and ſeede, all of them or any of them are very cordiall and helpe to expell penſiveneſſe and melancholie, that ariſeth without manifeſt cauſe, whereof came the ſaying, *Ego Borrago gaudia ſemper ago*, and as I ſayd before called *Corrago*: it helpeth alſo to clarifie the blood and mitigate the heate in feavers: the juice made into a Syrupe prevaileth much to all the purpoſes aforeſaid, and is alſo put with other cooling opening and clenſing herbes to open obſtructions, and to helpe the yellow Iaundies, to coole and clenſe the blood and temper the heate and ſharpeneſſe thereof, eſpecially with *Fumitery* and thereby to helpe the Itch, Ringwormes or Tetters or other ſpreading ſcabbes or ſores that ariſe from aduſt and ſharpe

humors

humors and for that purpoſe is put into the *Syrupus Byzantinus*, which worketh to the ſame effect: the Conſerve made of the flowers, or the flowers candid are helping alſo in all thoſe cauſes, but are chiefely uſed as a Cordiall, and good for thoſe that have beene long ſicke and feeble or in a Conſumption, to comfort the heart and ſpirits, and thereby good for thoſe that are troubled with often ſwounings or paſſions of the heart. The deſtilled water is no leſſe effectuall to all the purpoſes aforeſayd; and the eyes waſhed therewith helpeth the redneſſe and inflammations of them: the dryed herbe is never uſed but the greene, yet the aſhes thereof boyled in mede or honied water is availeable againſt inflammations and Vlcers in the mouth or throate, to waſh and gargle it therewith: the rootes of Bugloſſe are much more clammy and glewiſh then of Borrage and therefore by ſome good Phyſitions not held ſo convenient to be uſed in opening decoctions: for it is thought by the tenacious muccilagines in them, they rather helpe to binde then open obſtructions, but may be effectuall in a Lohoc or licking Electuary for the cough, and to helpe to condenſate thin flegme and rheumaticke deſtillations upon the Lungs. Theſe other ſorts of wilde Borrage or Bugloſſe are ſomewhat hotter and dryer, and are very neare unto the propertie of *Echium* Vipers Bugloſſe whoſe Vertues I ſhall not neede here to reiterate, I ſhall rather referre you to their Chapter to be informed in the particulars thereof.

CHAP. XXI.

Cucurbita. Gourdes.

THere is ſo great a likeneſſe of Gourdes, Melons or Pompions, Muskemelons, Cowcumbers, and Citrinilles one unto another, both in their manner of growing, and qualitie of cooling, that the ancient Greekes, and others have much confounded them together, yet they doe each notably differre one from another, both in the forme of their fruite and ſeede, beſides their ſiſe and colour. I have in my former Booke ſet forth the ſorts, both of Muskemelons, and garden Cowcumbers, whereof I ſhall not neede to ſpeake againe here, although I may give you ſome of their figures: of the wild Cowcumber, as alſo of the wilde or bitter Gourde called *Colocynthis*, I have ſpoken in the ſecond Claſſis of this Worke before: divers ſorts of Gourdes remaine to be entreated of, whereof the Pompion is a peculiar kinde, and having ſpoken of the garden kinde thereof alſo in my former Booke, I entend not to repeate it againe, but of ſome ſtrange wilde kinds; I muſt here comprehend under the Gourds, although their ſeedes doe differ *Citrulli Citrulles*, which are accounted by divers to be kindes of Cowcumbers, but I doe rather referre them alſo to the Gourds, becauſe their ſeedes have hard ſhells, ſuch as neither Melons nor Cowcumbers have, which two are of ſo neare affinitie, that their ſeede is very hardly diſtinguiſhed. Of Citrulles I ſhall entreate in the next Chapter, and of the Gourds in this, and with them ſome ſuch ſtrange fruites as have come to our ſight or knowledge from forraine parts, whereof we tooke the figures, and that after I have given you ſome of their deſcriptions to ſave many repetitions.

1. *Cucurbita lagenaria major.* The greater bottle Gourde.

This great Gourd groweth as all other of theſe kinds of herbes do ſpreading many great, rough and hairy armes and branches, with ſeverall great and broad leaves, ſoft and almoſt round, yet pointed at the ends, and ſometimes dented about the edges ſet upon long footeſtalkes and long claſping tendrills like a vine, ſet at other joynts whereby it climeth, taking hold and winding it ſelfe about whatſoever poles, arbours, trees or other things that ſtand next unto it, or elſe not having whereon to clime and raiſe it ſelfe, it lyeth on the ground ſpreading a great compaſſe as the Pompion doth, at the ſeverall joynts likewiſe with the leaves come forth ſeverall flowers in the ſame manner as Pompions, Cowcumbers or Melons doe, but are very large hollow bells ending in five points or corners with a round greene head under each of them that will beare fruit, for many flowers wither and beare no fruit, not having that round greene head under the flowers which ſhould grow to be the fruit, and will be full and ready to come forwards with the ſhort ſtiffe ſtalke under it, the colour of the flowers are either white, or pale white, or pale yellow, the fruit when it is ripe hath an hard outer rind or ſhell, yellowiſh, large and round bellied, flat at the bottome like unto a bottle and ſmaller up to the necke, above which is a ſmall round formed head whereunto the ſtalke is faſtned, and ſometimes without any ſmall head, being pendulous or hanging downe not ſtanding forth or upright, within which fruit lye diſperſedly many ſeedes, having ſmooth hard wooddy ſhells, flat and broad at the upper end or head, and ſomewhat pointed below, wherein lyeth a ſweete white kernell: the roote conſiſteth of many long ſtrings ſpreading much within the ground but periſheth uſually with the firſt froſts.

2. *Cucurbita lagenaria minor.* The leſſer bottle Gourd.

This differeth from the former in nothing but that it is ſmaller in every part as well leaves ſtalkes flowers as fruit, which is of the ſame forme but ſmaller.

3. *Cucurbita longa.* The long Gourd.

This Gourd alſo differeth little but in the fruit and ſeede from the former, for the fruite groweth long and ſometimes crooked or bending like a horne, almoſt of an equall ſiſe all the length which in ſome places groweth to be of an incredible length, eſpecially when the fruit hangeth downe from ſome high place, otherwiſe lying on the ground, it never attaineth to halfe that length, whoſe outer Rinde is yellowiſh in the hotter climates as the other ſort is, but with us whitiſh, and ſeede therein, ſomewhat whitiſh with us, and not ſo broad at the head nor ſo hard.

4. *Cucurbita clypeiformis ſive laciniata.* The Buckler or Simnell Gourd.

There is a manifeſt difference not onely in the fruite of this Gourd from the reſt but in the manner of growing alſo, for it groweth upright with great hollow rough hairy creſted ſtalkes, to the height of three cubites, and runneth not along on the ground as the reſt, having greater leaves rough and hairy ſet thereon, of a ſad greene colour, and more cut in or divided on the edges: the flowers are bell faſhion like the others, of a faint yellowiſh colour ſtanding upon the head of the fruite which growing to ripeneſſe is ſomewhat big and round toward the ſtalke but flat forewards, with a crumpled verge or brim, ſomewhat cut in or endented, and thinner there then in any other place, the forme doth much reſemble thoſe ſodden baked cakes that are made in Lent time which wee call

1. *Cucurbita lagenaria major.*
The greatest round bottle Gourd.

3. *Cucurbita longa.* The long Gourd.

4. 5. *Cucurbita Clypeiformis & verrucosa & Anguria Ægyptiaca.*
The Simnell and the rugged Gourd, And the *Egyptian* Citrull or watery Million.

Cucurbitæ Indicæ, Ovalis, Pyriformis & fere rotundus.
Indian Gourds, Ovall, Peare fashion, and almost round.

call Simnells, which thereupon I have so entituled, or else Bucklers as others do thinke which you please: the pulpe or meate within is firme & cutteth like an Apple, without any hollownesse in the middle but where the seede lyeth, which is somewhat like unto the Kernell of an Apple, but greater, broader, and flatter at the head.

5. *Cucurbita verrucosa.* Rugged Gourds.

The difference herein consisteth onely in the round fruit, whose shell or barke is not smooth as in others, but rugged, set as it were with knobbes and warts.

6. Cucurbitæ hyemales. Wanter Gourds or Millions.

These Gourds differ little in forme of growing from the other sorts before mentioned but in the maturitie and durabilitie of their fruite: for there are of them that are greater then others, and of different colours, as some yellow others greene or of other colours: but all of them doe ripen later, and doe better endure the first approach of Winter then the others, for they are not full ripe and fit to be eaten before they are hung up in a Chamber after they be gathered.

7. Cucurbitæ Indicæ rotundæ & diversi formes.

Round *Indian* Gourds, or Millions, or Pom pions, and of other formes.

There is very great varietie of these Gourds (or Millions as some call them, or Pompions, as I may call some of them) that come out of *America* or the West *Indies*, from sundry places, both farther South among the *Spanish* Colonies, and nearer hand in our owne of *Virginia, New-England, &c.* Some whereof in their forme are as round as long, some longer like a Peare, some more long then round, and some flat at the bottome: some also as great as our Pompions, some as small as an Apple, and some of divers other sises, meaner or greater or lesser, some with much moysture or water that is very sweete and pleasant in them, and some having little or no meate, or moysture: some againe discoloured on the outside, greene, with whitish or yellowish stripes in them, or spotted so finely that they give great delight to behold them, some also reddish spotted or striped, and some of a deepe yellow colour, the seedes in these likewise are variable in divers, some more like unto the ordinary Gourd seed, but blacker or browner, or red, in others white, either like the long Gourd, or like to our Pompions, yet few so large as our Pompion, and others as small almost as the Cowcumber seede, so that to give you an ample declaration of every one of them were a worke of curiositie, and of more travell then profit, and therefore I must leave it for them that can intend it, and will gather them all together and publish such a peece, I must convert my pen to other parts which I hope shall proove more beneficiall to the Commonwealth.

Divers other sorts of Gourds or Millions, or Pompions, or whatsoever else you please to call them, are growing and have beene brought us from sundry places, both *Syria* and the East *Indies* differing from many here expressed, some being as red as blood both within and without, and much pleasanter in eating then in any of these Countries, whereof to write more largely were almost superfluous, the diversitie being so great that we yearely almost see some sort not before seene of us, and therefore who so will may quote those they like in the margent or end hereof.

The Place.

All these Gourds are strangers and brought from severall places, some out of the *Levant*, as *Ægypt, Syria, &c.* others as I said before out of *America*, both further off and nearer to us, as in *Virginia, &c.*

The Time.

They are all to be planted of the seede in the Spring, and in very good ground that must not want plenty of moysture, or else the heate of our owne Country will not serve to ripen them.

The Names.

The Gourde is called in Greeke κολόκυνθη or κολόκυνθα ἐδώδιμος *Colocynthe edulis*, to shew the difference from the other κολόκυνθις or κολόκυνθα ἄγρος or ἀλεξανδρίνη or σικύα πικρά, the wilde or bitter Gourde called *Colocynthis* or *Coloquintida* before spoken of: in Latine *Cucurbita a concurvatu* (as it is thought) *quod facile siquid obsteterit quo minus extendatur incurvescat*: the Antients as I sayd in the beginning have beene very variable in their denominations of Gourdes, Cowcumbers, &c. for they have by the word σικύα whith is *Cicumis*, called divers other sorts of these fruits. *Athenæus* setteth it downe in his second booke that *Euthydamus* called the Gourde *Cucumis Indicas*, because as he there saith, the seede was first brought out of *India*, and that *Menodorus* made the Gourd to be of two sorts, the one of *India* called σικύα *cucumis*, the other called κολόκυνθη *colocyntha*. *Pliny* also in his 19. Booke and fift Chapter maketh the Pepo or Pompion, a kinde of Cowcumber, saying *Cucumeres cum magnitudine excessere Pepones vocari*, but *Galen* saith *lib. 2. alimentorum* that πέπων (which signifieth τὸ πέπαινον ripe, and may be appropriate to all fruits) is yet given to one peculiar, but then it is called σικυον πέπων *Pepo cucumeralis*, but hereof I shall speake a little more in the next Chapter. *Pliny* hath two sorts of Gourds, the one hee calleth *Cucurbita Cameraria*, because it was planted or placed neare unto Chambers and windowes to be a shade and coole refreshing from the heate, which by climing up and leading it which way they pleased it did performe, for as he saith it is *sublimitatis avida*: the other he called *Cucurbita plebeia*, which lay upon the ground and climed not, which I doubt whether it be any of those sorts here spoken of, for all of them except the *Clypeiformis* will clime if they have any high thing stand neare them whereon they may rise. The *Arabians* call them *Hara, Charha* and *Harakarha*, the *Italians Zucca*: the *Spaniards Calabassa*, the *French Courge* and *Coucourde*, the *Germans Kurbss*, the *Dutch Cauworderen*, and wee in *English* Gourds. The two first are called by *Lobel* and *Lugdunensis*, *Cucurbita lagenaria major & minor*, and *Cameraria major & minor*: the third is called *Cucurbita oblonga* by almost all Authors except *Dodonæus*, *Lobel* and *Gerard*, who call it *Cucurbita anguina*: the fourth is called *Cucurbita stellata & sessilis* by *Camerarius* and *Gesner in hortis*: by *Tabermontanus Cucurbita capitata*, by *Gerard Cucurbita sylvestris fungiformis*, *Pepo Indicus fungiformis*, and *Pepo maximus clypeatus*, for all these his three figures expresse but this one sort of Gourd, and by *Dodonæus Pepo latus*: the fift is called *Cucurbita Indica* by *Matthiolus*, *rotunda* of *Cæsalpinus* and *Lugdunensis*, and *Indica major* or *minor* of *Tabermontanus*: *Zuccha major rotunda* of *Cordus* and *Citrullus maior* and *Pepo maior sylvestris* of *Gerard*, which although he expresse these as he did the former for sundry plants yet they are not so: of this kinde *Matthiolus* and others have made mention of much varietie which they saw in their time, and wee I thinke in ours many more as I have declared before: the sixt is mentioned by *Lugdunensis* onely by the name of *Cucurbita verrucosa*: the last some call *Cucumeres hyemales*, but I had rather call it *Cucurbita hyemalis* partly for the reasons before set downe, but chiefely for the seeds sake which is more like a Gourd then a Cowcumber. What I said before concerning the variableness of the ancient Authors in these things, I may as well say of our moderne writers in confounding *Pepo, Melopepo* and *Cucurbita* so promiscuously, that it is not possible to finde out the distinct certaintie of them all, for some make that to bee *Pepo* that others call *Melopepo* and others *Cucurbita*. And *Bauhinus* who taketh upon him to refine all other mens writings and distinguish of them, in making *Pepo, Melopepo*, and *Cucurbita* severall kinds of plants, doth so huddle and confound them together, as any that will reade him advisedly and compare him may soone see that he giveth severall names to one and the same plant in divers places; which errour and the prolixitie about them

you

you see I have endeavoured as much as I can to avoyd. But to give you one note worth the observation to know the severall varieties of these and the other sorts of Millions, Citrulls, Cowcumbers, &c. is dilligently to marke the forme of the seedes, for the seede of the ordinary bottle Gourds are formed quite differing from all the other sorts, and therefore whatsoever strange seede shall come to your hands formed somewhat like unto them, you may certainly conclude them kinds of Gourds, so likewise of the Pompions or Millions which are flat, white, and greater then either Muske Melon or Cowcumber: in like manner the Citrull hath a thicke hard shelled blacke barcke and rounder then the Gourd, and therefore what seede is neareſt thereto in likenesse you may include them under their family, the Muske Melons and Cowcumbers are very like one unto another, and therefore I would conclude them both under one *genus*, yet if you will well observe them you shall soone know their difference by the yellower and harder shell of the Melon, & greater also when as those of the Cowcumber are whiter, smaller and tenderer shelled: I know none other of these kinds of fruites but may be most truly referred by their seede especially, but not either by forme, colour or taste, to one of these foure foreshewed sorts. Some other things more, before I leave this narration I thinke good to shew you, namely, the divers errours both of *Pliny* and others, both ancient and moderne, who thinke that all or most of these varieties of Gourdes have come from the seede of one kinde, *viz.* that the seede that lyeth in the necke of the Gourde will give long Gourdes, those in the middle round like Gourdes, and those in the bottome or lowest parts, flat or bottle like Gourds, and that the varietie of formes in them is also caused by the Art of Gardiners, who by mouldes and such like, doe bring them unto what forme they please, which forme, say they, they will continually keepe afterwards each from their own seede, which is found utterly untrue, for howsoever they may by mouldes, &c. bring them in their growing to the forme of the mould, yet the seede thereof assuredly will give no other forme than the first naturall, unlesse it be forced againe. Another errour or opinion possesseth many that by the standing of water in a pot three or foure foot off from the place where it groweth, it will shoote and spring wondrous fast, and that if oyle be set neare it, it will shrinke in as fast; and againe, that if women when they have their courses shall touch any part of them, it will hinder their growing: and lastly, that to make them come without seede, is to steepe the seede in oyle of *Sesamum* before you set it, all which are as erronious as the former.

The Vertues.

All these sorts of Gourdes how ever different in forme, yet are of one qualitie, that is, cold and moist in the second degree: they are eaten in the hot countries with much delight, kept and preserved with great care, art, and paines to be spent almost all the yeare after, and have there, as I said before, a farre more sweete and pleasant relish than in these colder climates, where being more waterish, they are the more unsavorie, at the least more insipide: they are eaten boyled or stewed, but much better being fried whereby they give the better nourishment to the body: for by their moisture being boiled or stewed, they are the more lubricke, and make the body the more soluble, and so they doe also being pickled up as many use to doe: Wine also kept in a fresh Gourde all night, after it hath beene clensed from the loose inward pulpe and seede and drunke in the morning will cause the body to be soluble. They are conveniently given to hot & cholericke bodies to coole the heat and inflammation of the liver and stomacke: but the distilled water of them before they are through ripe drunke with some Sugar, doth wonderfully helpe to asswage thirst, and the hot fits of agues. For want of a Still to make water, you may make some effectuall in this manner. Put a whole Gourd when you have cut off the upper head and clensed it from the seede, into an Oven with a batch of bread, in the middle whereof there will be gathered a fine cleare water, which being powred out, may be kept to use as neede requireth: the leaves and young branches are conveniently applied to all the hot humors, empostumes and inflammations, and to asswage paines of the headach, the redneſse and heat in the eyes, the paines in the eares, and the paines of the gout, if either the juice of them, or the water be applied in clothes and spunges wet therein: the same applied to womens breasts pained with the abundance of milke easeth them by cooling and restraining the hot qualitie and quantitie thereof: the water or juice being drunke or outwardly applied to the privie parts of man and woman, restraineth the immoderate lust of the body: the ashes of burnt Gourds are used of many to clense and heale old ulcers and sores, as well in the genitories, as other parts of the body, and to helpe scaldings or burnings by fire or water: they are accounted as good for macilent leane and weake bodies to feede on, as they are hurtfull to such as have the winde cholicke, to whom they are not to be given at any hand. The seedes of Gourds are one of the foure greater sorts of cold seedes used very much in Physicke, and are very availeable in decoctions, Iuleps, Emulsions or Almond milkes to coole the heate of the liver, the reines or backe and urine, and to give much ease to them that are troubled with the stone or gravell in the kidneyes, and the ulcers or sores of the inward parts and bladder. The Simnel Gourd being of a firmer substance dressed any good way, is both more acceptable meate, and is no lesse effectuall in medicine. The *Indian* sorts are some more waterish, others more solide, and accordingly are more or lesse fit for meate or medicine.

CHAP. XXII.

Anguria sive Citrullus. The Citrull or *Turkie* Million.

THe Citrull or *Turkie* Million hath also some varieties being a fruit different from the other, as well in the forme therof as of the seed, which much leadeth me to distinguish of them, or joyne them together, yet becaus some doe account them kindes of Cowcumbers, I will give you the figures both of some sorts of Cowcumbers and Muske Melons also.

1. *Anguria sive Citrullus vulgatior.* The ordinary Citrull or *Turkie* Million.

This kinde of Million groweth like as other Melons and Cowcumbers doe with rough trailing branches, the leaves whereof are hairy, longer and narrower than in any other, and more divided into severall parts, and hath small claspers and yellow flowers, but the fruit is greater than a Melon, somewhat neare the fashion of a Pompion, with a smooth greenish barke which will change yellow by time, having some ribbes thereon, the meate

Cucumis sativus.
The ordinary Cowcumbers.

Cucumis anguinus flexuosus:
The long bowed Cowcumber.

Melo Indicus parvus.
A small *Indian* Melon.

I. *Anguria sive Citrullus vulgatior.*
The ordinary Citrull or *Turkie* Million.

or inner ſubſtance is wateriſh, in ſome ſweete, in others a little tarte or ſoure, the ſeede whereof is ſmaller, rounder, blacker and harder ſhelled than thoſe of the Gourd, the roote ſpreadeth and dieth like the reſt.

2. *Anguria Americana verſicolore pelle.* The diſcoloured *Indian* Million.

This other ſort of Million varieth little from the former in growing, leaves or flowers, in the fruit is the chiefeſt difference, which is as great as a middle ſiſed Pompion with a diſcoloured barke very variably ſpotted and ſtriped with white ſpots and markes upon the greene, the inner ſubſtance whereof is wateriſh, yet ſomewhat firmer than of the former, and will keepe ſound for a good while after it is ripe and gathered, as the others alſo will, the ſeede within this is like the other, but longer, greater, redder, and more ſmooth and ſhining.

3. *Anguriæ Ægyptiacæ. Egyptian* Citrulls or Millions.

Some of theſe *Egyptian* fruites are greater than others, even ſo great as *Bellonius* ſaith that foure or ſixe will loade a camell, and one a man; the outer rinde being yellow, the inner meate or ſubſtance very little and almoſt emptie, filled in the middle with much water that is very ſweete, much deſired and drunke by them of the more reſpect, with Roſewater, Muske and Amber, and is the preſent they offer to ſtrangers whom they will chiefely entertaine; it hath a few ſmaller ſeedes within it than in the former, in other things there is little difference. I have given you the figure of this fruit in the former tripartite table in the foregoing Chapter.

4. *Anguria carne ligneſa.* Hard or Wooddy Millions.

Cæſalpinus maketh mention of this ſort as of a kinde of Cowcumber (for ſo the *Italians* doe call theſe ſorts of fruits that growing wilde or manured in other countries are nurſed up in *Italy* for delight and raritie) whoſe fruite is ſo hard and wooddy, that it will not breake being let fall upon the ground, but will rebound againe like a ball that is let fall: Hereof I have no further knowledge than his relation, that is, *teſtis fide dignus.*

The Place.

The firſt groweth generally throughout *Turkie*, and ſo likewiſe in all *Italy* and many other hot countries, where they doe account it for their beſt of Cowcumbers: the ſecond was given me among others rarities that came out of *America* or the *Weſt Indies*: the third is naturall to *Egypt*, as *Proſper Alpinus* ſaith in his Booke of *Egyptian* plants; and *Bellonius* in his ſecond Booke of Obſervations, and 75. Chapter: the laſt is not knowne or not mentioned where it is naturall.

The Time.

They flower and beare their fruit about the ſame ſeaſon that the others doe.

The Names.

It is thought by divers that this kinde of fruit was not knowne to the ancient Greeke or Latine Writers, and that *Ætius* did firſt make it knowne by the name of *Anguria*, from whom *Matthiolus* and others doe call it: others doe ſuppoſe that it is the *Pepo* of *Dioſcoridis*, *Galen*, and *Pliny*; but I thinke it not amiſſe here to relate the words of *Galen in* 8. *ſimpl. medicament. Univerſa Peponum natura frigidior, cum larga humiditate exiſtit: ſed habent quoque quandam abſtergendi vim: atqui Melopepones minus humidi, quam Pepones ſunt*; by which words one may more than halfe gheſſe which of theſe ſorts of fruites come neareſt unto *Pepo*, and *Melopepo* of *Galen*, and thoſe of his time, unleſſe our climate alter their ſubſtance or propertie. It is generally called *Citrulus* or *Citrullus a citreo colore & forma*, and *Cucumis Citrullus* by divers, to diſtinguiſh it from the other Cowcumber. In the Chapter before you have *Pliny* alledged to account the Cowcumbers that grow over great, to be called *Pepones*, and here you have that theſe *Citrulls* be accounted *Cucumeres* as *Cæſalpinus* and all *Italy* over doe account them commonly: ſo that you ſee how various mens opinions are in theſe ſorts of fruites, none knowing directly which of them is moſt truely the *Pepo* or *Melopepo* of the ancients, nor which is their *Citrulls*, whether this that beareth that name as the *Italians* take it, or our ordinary *Cucumis* commonly ſo called with us: *Alpinus* in his Booke of *Egyptian* plants, ſaith, that the *Egyptians* have divers of theſe ſorts of *Citrulls* differing one from another which they diſtinguiſh by the ſeverall names of *Chate*, *Abdolavi*, *Chajar &c.* Of the *Arabians* it is called *Batec*, and *Batecha*, and as it is thought is the *Dulhaha* of *Serapio*; but *Bellonius*, in the place before alledged, ſaith, that the *Egyptians* call it *Copons*, and that *Anguria* ſignifieth a Cowcumber, and is not this plant: of the *Italians Cocomero* and *Angoria*; of the *Spaniards Cogombro*, of the *French Citroulles*, of the high and low *Dutch* following the Latine name *Citrullus*, and ſo wee in *Engliſh*; as alſo *Turkie* Million or Cowcumber, becauſe that others doe call it *Cucumis Turcicus.*

The Vertues.

The Citrull is of the ſame temperature with the Gourde, that is, cold and moiſt: the ſeede is moſt of uſe in the Apothecaries ſhoppes, and reckoned one of the foure greater cold ſeedes, being uſed as Gourdes, Millions, and Cowcumbers to coole the heate of the fits of agues, and the diſtemperature of the liver and bloud, to quench thirſt, and to take away the drineſſe and roughneſſe of the tongue cauſed thereby, and is as availeable for the ſtone, the heate of the raines, and the ſharpeneſſe and ſtopping of urine as any of the reſt. It is thought more convenient for macilent bodies, and that are growne feeble and weake by long ſickneſſe, in regard of the greater ſweetneſſe more than in the Gourde, as aforeſaid: and generally both leaves, branches, juyce and diſtilled water hereof, is as effectually applied for all thoſe diſeaſes that the Gourdes before mentioned are, and therefore needs not againe be repeated. I ſhall referre you to the Chapter going before for the reſt.

CHAP. XXIII.

Intubaceæ plantæ. Endive or Succory like herbes or plants.

VNder this generall name of *Plantæ Intubaceæ* Succory like herbes, is comprehended ſo great a varietie, that to expreſſe them in ſome methodicall manner, I muſt diſtribute them into ſeverall Chapters under their principall heads or titles, whereunto they are to be referred, which are, *Endivia*, *Cichorium*, *Dens Leonis*, *Chondrilla*, *Sonchus*, *Lampſana*, *Hieracium*, *Lactuca*, *Senetio*, and *Iacobæa*; of ſome of which I have ſpoken both in my former Booke, namely of all the ſorts of Garden Lettice, and in this Worke of all the ſorts of *Iacobæa* and *Senetio*. Firſt then to beginne with Endive, the kindes whereof alſo I have ſhewed

Endivia ſativa.
Garden Endive.

Intubus ſive Endivia minor anguſtifolia.
Small Garden Endive.

you in my former Booke, and therefore I will make no further deſcription of them, but give you the figure of the uſuall garden kinde, and expreſſe a wilde ſort here, but withall ſet out the Vertues of them more amply than formerly I have done.

Intubus ſive Endivia minor anguſtifolia. Small garden Endive.

This ſmall Endive hath many very long leaves lying on the ground, narrower than the firſt garden Endive, and ſomewhat more bitter: the ſtalke is ſlenderer, more full of branches, and lower than the other, bearing at the tops ſmall blew flowers like the common Endive, after which follow the like ſeede alſo, and the roote periſhing in like mannner.

The Place.

This is onely planted in Gardens, as well beyond the ſeas as in our country as the other ſorts are.

The Time.

It flowreth and periſheth with the other ſorts if it be ſowen in the Spring, but if at Midſommer it will then abide the beginning of Winter, and will well ſerve to be uſed as the others be.

The Names.

The Greek word Σέρις as the Latine *Intibus*; *Intubus* or *Intubum*, doth denominate as well Endive as Succory, and therefore both they and the kinds therof are called after the Greek *Serides*, or *Intubaceæ* after the Latin: *Dioſcorides* maketh two kindes of *Seris*, the one tame, the other wilde, and of each two ſorts, of the tame, he ſaith the one hath a broad leafe like unto Lettice, which is our ordinary garden kind, and called by *Matthiolus Intubus major*, and of others *Intubum ſativum*; the other hath a narrow leafe, and is ſomewhat bitter in taſte, which is this Endive here ſet forth by the judgement of the beſt moderne writers, and is called by *Matthiolus Intubus* and, *Endivia minor*, by *Lacuna Intubus hortenſis alter*, by *Geſner in hortis Intubum anguſtifolium Scariola aliquibus*; by *Cluſius in hiſtoria plantarum Cichorium ſativum*; by *Lobel Seriola aut Endiviola*, who ſaith that the name of *Scariola* given to this Endive, was but the corruption of the times, which ſhould have beene called *Seriola quaſi parva Seris*, and therefore whereſoever *Scariola* is appointed in any medicine, this ſort of Endive is intended thereby and ſhould be uſed. Endive is called by the *Arabians Dumbebe Anubebe* or *Endeba*, by the *Italians Endivia*, and this ſmall kinde *Endivia minore* (and in the Apothecaries ſhoppes beyond the ſeas *Scariola domeſtica*) by the *Spaniards Endivia*, by the *French Endivie*, by the *Germanes Endivien*, by the *Dutch Endivie*, and by us in *Engliſh* Endive, and this ſort ſmall Endive.

The Vertues.

All the garden Endives are cold in the ſecond degree at the leaſt, but are more moiſt and leſſe drie than Succory or the kinds thereof which is more bitter, and ſerveth well to coole the exceſſive heate in the liver and ſtomacke, and in the hot fits of agues, and all other inflammations in any part of the body, to uſe the decoction of the leaves or the juyce or diſtilled water: the ſame alſo helpeth to coole the heate and ſharpeneſſe in the urine, and the excoriations in the uritorie parts: the ſeede is of the ſame propertie, or rather more powerfull, and beſides is available for the faintings and ſwounings and paſſions of the heart: outwardly applied they ſerve to temper the

ſharpe

ſharpe humours of fretting ulcers, hot tumors and ſwellings, and peſtintiall ſores; and wonderfully helpeth, not onely the redneſſe and inflammations in the eyes, but the dimmeneſſe of the ſight alſo: they are alſo uſed to allay the paines of the goute. They are all uſed in ſallats familiarly both Summer and Winter, when as being whited, they are the more tender and delicate very pleaſing to the ſtomacke, and refreſhing the weake and fainting ſpirits.

CHAP. XXIIII.

Cichorium. Succory.

OF the Succories there are many ſorts, ſome accounted tame or of the Garden, others wilde or of the fields, &c. of the moſt uſuall Garden kinde I have ſpoken in my former booke, and of the other ſorts I am to entreate here, but becauſe I ſhould peſter one place too much to ſet them forth all in one Chapter, I muſt handle them ſeverally, and ſpeake of thoſe kinds of Succory here in this Chapter that beare blew flowers or come neareſt the Garden kinde and of others that beare yellow flowers in the Chapter following.

1. *Cichorium flore rubello.* Red flowred Succory.

The red flowred Succory is in the long leaves a little more divided on the edges in the tall and high round ſtalkes, in the forme of the flowers and ſeede and in the long white roote, abiding yearely like unto the Garden Succory, the onely difference hereof conſiſteth in the colour of the flowers, which in this are of a pale red delayed colour, which will degenerate as I have often obſerved in my Garden, turning to bee blew, I meane thoſe plants that riſe from the ſeede of the red, and not the ſame plants that have borne red flowers.

Of this kinde likewiſe there is one that beareth white flowers, not differing elſe, but that the ſeede hereof as well as the other will give blew flowred plants. *Flore albo.*

2. *Cichorium ſylveſtre.* Wilde Succory.

Wilde Succory hath divers long leaves lying on the ground very much cut in or torne on the edges, on both ſides even to the middle ribbe ending in a point, ſometimes it is found to have a red ribbe or veyne downe the middle of the leaves, from among which riſeth up a hard round wooddy ſtalke ſpreading into many branches, ſet with ſmaller and leſſer divided leaves on them up to the toppes, where ſtand the flowers, both for forme and colour like unto the Garden kinde that is of a blew colour, after which come the ſeede like thereunto alſo: the roote is white but more hard and wooddy then the other: the whole plant is exceeding bitter.

3. *Cichorium ſpinoſum Creticum.* Thorny Succory of *Candy.*

This Thorny Succory hath the lower leaves next the ground ſomewhat long and narrow, cut in ſomewhat roundly on the edges like the ordinary Succory into many ſhort not deepe cuts; the creſted greene ſtalke that ri-

Cichorium ſativum vulgare.
Ordinary Garden Succory.

1. *Cichorium ſativum flore rubello.*
Garden Succory with red flowers.

2. *Cichorium ſylveſtre.* Wilde Succory.

3. *Cichorium ſpinoſum creticum.* Thorny Succory of *Candy*.

ſeth from among them is hard and wooddy, ſpreading many ſuch like branches from the very bottome all about, making it ſeeme a round buſh ſet with many narrower leaves, and without any cut or diviſion on the edges which quickly fall away leaving the ſtalkes bare or naked, and each branch ending in one, two, or three ſometimes long forked thornes: at the joynts with the leaves, which towards the toppes abide a little longer, come forth ſmall ſcaly huskes, and out of them the flowers which are made of five leaves a peece broade at the ends, and cut into two or thee dents of a blewiſh colour like unto Succory with ſome yellow threds in the middle: the ſeede that followeth is like the ordinary ſort, and ſo is the roote, but ſomewhat thicker and ſhorter, and abideth as the Succory doth.

The Place.

The firſt ſort is found wilde in ſome places of *Italy* from whence I had the ſeede, and the white one in *Germany*: the ſecond is found in many places of our Land in waſte, untilled, and barren fields: the third by the Sea coaſts and other ſandy grounds in *Candy*.

The Time.

The two firſt ſorts flower in the time that the other common ſort doth, but the laſt not untill *Auguſt*, and hardly then, ſo that in our Country it doth give no ſeede, neither will well indure our Winters.

The Names.

Σέρις in Greeke as I ſaid before in the laſt Chapter, and *Intubum* in Latine doe ſignifie Succory as well as *Endive*, and the wild ſort of Succory is called σέρις πικρὶς *ſeris picris* becauſe it is more bitter then the reſt. Some take *Hieracium* and ſome *Lactuca ſylveſtris* to bee *Seris* or *Intubum ſylveſtre*, but *Matthiolus* conteſteth againſt them, in Latine alſo *Cichorium ſylveſtre*. *Pliny lib.* 22. *cap.* 8. ſaith that this *Intubum ſylveſtre* or *Picris* or *Cichorium erraticum* was called by ſome in his time *Ambugia*, but *Celſus* and ſome truer copies have *Ambubeia*, *Theophraſtus* calleth it κιχόρη and κιχόριον, *Horace* hath *Cichoreum* or *Cichorea*, where he ſaith,

Me paſcunt Olivæ,
Me Cichorea, leveſque Malvæ. *Tragus* alſo hath *Cichorea*.

Of the firſt with red flowers I finde *Tragus* (to note one that hath *partim candidum partim roſeum florem* and from him *Bauhinus*) to make mention, and *Thalius in Harcynia ſylva* of that with white flowers: the ſecond is called by *Lobel Seris picris*, *Cichoriũ* & *Seris ſylveſtris*, by *Geſner Intubum ſylveſtre* and *Cichorium ſylveſtre*, and *agreſte* by *Lonicerus*, by *Lugdunenſis Hypocheris Dalechampij*, whereof *Theophraſtus* maketh mention in his ſeventh Book and 11. Chap. among the *Cichoriacea*, which *Gaza* untowardly tranſlateth *Porcellia*, *Brunfelſius* calleth it *Solſequium*, and *Gerard* putteth the figure hereof under the title of *Hieracium latifolium*, and *Bauhinus* noteth it: the third was firſt mentioned by *Honorius Bellus* in his fourth Epiſtle to *Cluſius* by the name of *Cichorium ſpinoſum*, and *Scamnagati id eſt*, *Hydriæ ſpina* by the *Cretans*: *Cluſius* in his hiſtory of Plants calleth it *Chondrillæ elegans genus flore cæruleo*, and afterwards both by *Pona* in his *Italian* deſcription of Mount *Baldus*, and by *Bauhinus* in his *Matthiolus* and *Prodromus Cichorium ſpinoſum Creticum*: the *Italians* call Succory *Giraſole*, *Radicchio*, *Scariola* and *Cicorea*, and the wilde

wilde kinde *Cicorea ſalvatica*: the *Spaniards Almenera* and *Cicoria ſalvaja*, the *French Cichoree ſauvage*, by the *Germans Wegwant*, by the *Dutch Cichorrey*, and by us in *Engliſh* Succory, and wilde Succory.

The Vertues.

Garden Succory as it is bitter is more dry and leſſe cold then Endive, and thereby more opening alſo. An handfull of the leaves or rootes hereof boyled in wine or water, and a draught thereof drunke faſting driveth forth chollericke and flegmaticke humors: the ſame alſo openeth the obſtructions of the Liver, Gall, and Spleene, and helpeth the Yellow Iaundies, the heate of the Reines and of the Vrine, the Dropſie alſo, and thoſe that have an evill diſpoſition in their bodies by long ſickneſſe, evill dyet, &c. which diſeaſe the Greekes call καχεξία *Cachexia*, a decoction thereof made with wine and drunk is very effectuall againſt long lingering Agues: and a dramme of the ſeede in powder drunke in wine before the fit of an Ague doth helpe to drive it away, the diſtilled water of the herbe and flowers performeth the ſame properties aforeſaid, and is eſpeciall good for hot ſtomacks, and in Agues either peſtilentiall or of long continuance, and for ſwoundings and paſſions of the heart, for the heate and headach in children, and to temper the diſtemperature of the blood and Liver: the ſaid water, or the juice or the bruiſed leaves applyed outwardly allayeth tumors, inflammations, S. *Anthonies* fire, puſhes, wheales and pimples, eſpecially uſed with a little Vinegar, as alſo to waſh peſtiferous ſores: the ſaid water is very effectuall for ſore eyes, that are inflamed or have any redneſſe in them, and for Nurſes ſore breaſts that are pained by the aboundance of milke. The wild Succory as it is more bitter, ſo it is more ſtrengthning to the ſtomack and Liver.

CHAP. XXV.

Pſeudo-cichoria ſive Cichoria ſylveſtria floribus luteis. Baſtard or wilde Succory with yellow flowers.

THere are divers other herbes which are accounted kindes of wilde Succory for their neare reſemblance in forme but not in qualitie thereunto, ſome whereof ſhall be ſet forth in this Chapter, eſpecially ſuch as beare the title of *Cichorium* Succory: For the *Dens Leonis*, *Dandelion* and the *Chondrilla*, Gum Succory that be kinds of Succory alſo ſo like unto it, that many have miſtaken the one for the other ſhall follow in their order.

1. *Cichorium pratenſe luteum aſperum*, Rough yellow field Succory.

This rough yellow Succory hath longer and rougher leaves then thoſe of the former wilde Succory, in one ſort with few or no cuts at all, in others like unto it with deepe cuts and diviſions: the ſtalkes grow to bee three or foure foote high, rough and creſted, divided into ſundry branches with ſmaller leaves on them, and leſſe jagged bearing ſmall yellow flowers like unto an Hawkeweede, at the ends of every one, which when they are ripe turne into downe, with a ſmall long yellowiſh ſeede faſtned thereat, and are both carried away with the winde: the roote is hard, rough and unprofitable.

2. *Cichorium pratenſe luteum Hedypnois dictum.*
Smooth yellow Succory.

4. *Cichorium veſicarium pratenſe.*
Bliſtered yellow Succory.

2. Cicho-

2. *Cichorium pratense luteum lævius.* Smooth yellow Succory.

This other yellow Succory hath long and large leaves, as ſmooth as Succory, but of a whiter greene colour, cut in on the edges, but not ſo much nor ſo deepe as the former: the ſtalkes riſe not up ſo high nor are ſo much branched, the leaves thereon are leſſe cut in, and up higher little or nothing at all: the greene heads that ſtand at the toppes of the branches are greater, and the flowers that ſpring out of them are larger and more double, ſomewhat like thoſe of Dandelion of a yellow colour, which turne into downe, and the ſeede therewith blowne away with the winde: the roote is full of a bitter milke.

3. *Cichorium ſylveſtre Hiſpanicum pumilum.* Dwarfe *Spaniſh* yellow Succory.

Of this laſt kinde *Guillaime Boel* found a dwarfe plant neare the Sea in the Iſle of *Cales* in *Spaine*, which by mine owne ſight and *Cluſius* judgement, as he recordeth it in his *Curæ Poſteriores* differeth not in any thing from the laſt but in growing leſſe in every part. Why *Bauhinus* ſhould make this a *Dens Leonis* rather then the former, (which for their ſeedes ſake may be ſo accounted) as he ſetteth it downe in his *Pinax*, I cannot ſee any juſt cauſe for ſure I am he never ſaw the plant, *& unus oculatus teſtis, &c.*

4. *Cichorium veſicarium pratenſe.* Bliſtered yellow Succory.

This kinde of Succory is in forme of leaves, bigneſſe, and colour ſo like unto the ordinary Garden Succory that it is often taken for the ſame, eſpecially in the Winter and the beginning of the Spring time, before it beginneth to ſhoote up ſtalkes, for during that time it ſpreadeth his many leaves round upon the ground, ſometimes broad and whole, almoſt without or with very few deviſions or jagges, and ſometimes alſo ſomewhat hairy or rough, in others ſmooth and more divided, of a ſhining greene colour: from the middle of them groweth a skinny bladder, out of which in the Spring riſeth up a round hairy ſtalke parted into many branches, ſomewhat rough and creſted, ſet with leſſer divided but ſhorter and broader leaves then thoſe below, at the toppe whereof out of the skinny bladder doe the flowers breake forth many ſtanding together, each upon a footeſtalke, each riſing out of a long greene huske like unto thoſe of Hawkeweede and conſiſt of many yellowiſh leaves, ſomewhat purpliſh underneath with ſundry threds as a thrumme in the middle, which turne into downe, and with the ſeede is carryed away at the will of the winde: the roote is ſomewhat long and ſlender, blackiſh on the outſide, and white within, yeelding a bitter milke as the reſt of the plant doth.

5. *Cichorium dulce Neapolitanum.* Sweete yellow Succory of *Naples.*

The ſweete Succory is in the forme and diviſions of the leaves very like unto the uſuall wilde Succory, yet not ſo deepely gaſhed, but thicker in feeling, covered with a fine ſoft hairineſſe not rough at all, and of a darke greene colour; the ſtalke riſeth to be two foote high or more, round, firme and whitiſh becauſe of the hoarineſſe thereon, ſometimes breaking out into branches toward the toppe, ſet with ſhorter ſomewhat broader and more divided leaves then below, cloſing the ſtalkes at the bottomes, having at their toppes greene hairy heads or huskes and gold yellow flowers in long hairy huskes like unto the Hawkeweedes, which growing greater when they are ripe within them is contained very ſmall long browniſh ſeede, with a fine white downe on them, and both carried away with the winde, the roote is long and blackiſh on the outſide and white within, ſo full of a ſweet

5. *Cichorium dulce Neapolitanum.*
Sweete yellow Succory of *Naples.*

8. *Zacyntha ſive Cichorium verrucarium.*
Warted Succory.

milke

milke without any bitterneſſe at all and ſo is the reſt of the plant, that it will grow hard like a gum if it bee not rubbed away but ſuffered to abide.

6. *Cichorium montanum aſperum.* Rough Mountaine Succory.

This mountaine Succory hath divers long narrow leaves next the ground very ſharpely dented about the edges but not divided or cut in at all, rough alſo all over: from among which riſeth up a ſtalke branched forth with ſuch like leaves ſet thereon and divers large double yellow flowers like unto thoſe of Dandelion at the toppes, which turne into downe as the reſt and blowne away: the roote conſiſteth of many long ſtrings.

7. *Cichorium tomentoſum fœtidum.* Strong or ill ſented hoary Succory.

This kind of ill ſented hoary Succory from a thicke roote ſendeth forth ſundry weake, round, hairy or hoary ſtalkes about two foote or more high, having divers large long hairy or hoary leaves next the ground, deepely gaſhed in on both ſides, ſomewhat like to Succory leaves, parted into many branches with leſſer leaves thereon then thoſe below, and leſſer cut alſo, at the toppes of whom ſtand many pale yellow flowers in greene huskes, like unto Groundſell which quickly fade in like manner turning into downe, which with the ſeede is carried away in the winde: this herbe hath ſomewhat an ill or ſtrong ſent with it, yet more in the hotter time of the yeare then elſe, which procured it the denomination of *fœtidum* ſtinking.

8. *Zacyntha ſive Cichorium Verrucarium.* Warted Succory.

The warted Succory ſpreadeth ſundry long and ſomewhat hairy greene leaves next the ground, cut or divided on the edges into deepe dents, but not deepe gaſhes, ſomewhat reſembling Succory leaves: the ſtraked ſtalkes divide themſelves into ſome leſſer branches with a ſmall long leafe at every joynt broad below and compaſſing it about at the bottome: the flowers grow ſeverally at the toppes and upper joynts of the branches upon ſhort footeſtalkes being ſmall and yellow, compoſed of divers ſmall yellow leaves, broad pointed and nicked in, which turne not into downe as the other ſorts before doe, but into ſmall round and flat hard heads, parted at the brims into ſundry bunches or knobbes like unto wartes with a little tuft or crowne in the middle, in each bunch whereof is contained a kernell or ſeede: the roote is ſmall and ſtringy dying every yeare after ſeedetime, and never abiding a Winter unleſſe it ſpring up from the ſeede in *Autumne*.

The Place.

The firſt two ſorts and the ſixt are many times found in our medowes and other moiſt grounds taken by moſt for kinds of Hawkeweeds and ſo the leſſe regarded: the fourth and fift *Columna* found on the hills in *Naples*; the ſeaventh is often found in ſandy grounds and by woods and hedges ſides: and the laſt is thought to grow in the Iſland *Zacyntha* from whence it was brought into *Italy*, and thence into other parts, but *Pena* ſaith it groweth in divers places in *Italy*.

The Time.

They doe all flower and ſeede about the ſame time of the other Succories, except the ſecond, which flowreth earlier then the reſt.

The Names:

All theſe herbes are accounted ſeverall ſorts of Succory by many writers, and ſome of them (that is thoſe of *Naples* as *Columna* ſaith) are uſed in the ſtead of the true Succory with good ſucceſſe, but as I ſaid before they are but baſtard ſorts which their ſeedes declare, being rather Hawkeweedes as I doe thinke: The firſt is called by *Geſner* in *Collectione ſtirpium Hieratium pratenſe aſperum*, by *Tabermontanus* and *Gerard Cichorium luteum*, by *Thalius Intubus ſylveſtris ſive Cichorium ſylveſtre flore luteo*, *Tragus* maketh it his *Cichorea 3. flore luteo*, and *Cæſalpinus* calleth it *Lactariola altera*: the ſecond is the *Cichoreum luteum pratenſe* of *Lobel* in *Adverſarijs* and *Hedipnois Plinij* and *Aphaca Theophraſti* in his Obſervations, as *Dalechampius* before him had done, and as *Lugdunenſis* ſetteth is downe for *Aphace Dalechampij*, *Cæſalpinus* calleth it *Endivia ſylveſtris*, and *Garard Dens leonis Cichorizata*, *Dodonæus* and *Tabermontanus* make it their third kind of *Dens leonis*, and *Bauhinus* calleth it *Cichorium pratenſe, luteum lævius*; the third is ſufficiently expreſſed in the deſcription: the fourth and fift *Columna* maketh mention of, the one under the name of *Cichorium ſylveſtre veſicarium pratenſe*, and the other of *Cichorium ſylveſtre aſperum amœnis, ſive Cichorium dulce*, which *Bauhinus* numbreth among the Sow Thiſtles and calleth it *Sonchus latifolius leviter hirſutus*: The ſixt is *Tabermontanus* ninth ſort of *Hieracium*, which he calleth *Hieracium Intabaceum aſperum*, and *Gerard Hieratium eſperum*: the laſt was firſt called by *Matthiolus Zacyntha ſive Cichorium verrucarium* and ſo doth *Cluſius* alſo: but *Lobel* in his Obſervations, Fol. 116. (in calling it *Chondrilla verrucaria, Chondrilla prior Dioſcoridis Cluſii Zacyntha Matthioli*) doth foulely confound the two plants of *Matthiolus* and *Cluſius* together, for he there giveth the thicke woolly leaves of *Cluſius* his *Chondrilla* to this *Zacyntha* of *Matthiolus* which hath greene leaves, and maketh it firſt to have creſted heads of ſeede as the true *Zacyntha* hath, and afterwards ſaith the flower is yellow, &c. flying away in downe utterly contrarying himſelfe, which *Cluſius* tooke knowledge of and found fault with him for it, and thereupon ſet forth the true figure and deſcription of it in his hiſtory of plants: *Geſner in hortis* calleth it *Verrucaria Seridis ſpecies*, and *Cæſalpinus Condrillæ ſpecies in ruderibus*, whereupon *Bauhinus* putteth it among his *Chondrillas*, and calleth it *Chondrilla verrucaria folijs Intubaceis viridibus*: the *Italians* call it *Mazzo di Cavalliero* and *Mazza ferrata*.

The Vertues.

Theſe kinds of Succories except the Neapolitane and the laſt are not uſed in Phyſicke that I know but they, that is the Neapolitane kinds as *Columna* ſaith are there uſed in ſtead of the true Succory, being ſo like it that as I ſaid in the deſcription they ſoone deceive one, miſtaking one for another yet uſed with good ſucceſſe whereby we may judge of the others not to be much differing, and therefore untill ſome further and more certaine experience bee made of them, let this adviſe ſerve for the preſent. *Matthiolus* hath given us firſt knowledge of the propertie of *Zacyntha* or warted Succory, from *Calzolarius* of *Verona*, who by practiſe had found it to be availeable to take away warts from the hands by once eating the leaves as a Sallet; and *Matthiolus* ſaith that by his owne experience a dram of the ſeede in powder taken for certaine dayes together in white wine to bedwards tooke away the warts from ones hands that was wonderfully peſtered with them: but *Pena* denying that the once eating of the leaves will doe any good, but yet ſaith that if the juice of the leaves bee uſed to bathe the warts, it will extirpate them moſt certainely as he and divers other found by their experience, the ſame alſo taken in wine helpeth the biting of a mad Dog.

CHAP.

CHAP. XXVI.

Dens leonis. Dandelion.

THe Dandelion is assuredly a differing kinde of wilde yellow Succory, and therefore I thinke it meete to expresse it before the *Chondrilla* Gumme Succory which is also an other kinde: hereof there are more differences and varieties found out of late than have formerly beene knowne, which shall be set forth here together.

1. *Dens leonis vulgaris.* Common Dandelion.

Our common Dandelion is well knowne to have many long and deepely gashed leaves lying on the ground round about the head of the roote, the ends of each gash or jagge on both sides looking downeward to the roote againe, the middle ribbe being white which being broken yeeld abundance of bitter milke, but the roote much more from among the leaves which alwayes abide greene, arise many slender weake naked foote stalkes, rather than stalkes, every one of them bearing at the toppe one large yellow flower, consisting of many rowes of yellow leaves broad at the points and nicked in, with a deepe spot of yellow in the middle, which growing ripe the greene huske wherein the flower stood, turneth it selfe downe to the stalke, and the head of downe becommeth as round as a ball with long reddish seede undernath bearing apart of the downe on the head of every one which together is blowne away with the wind, or with the blast of ones mouth may be blowne away at once: the roote groweth downewards exceeding deepe, which being broken off within the ground will notwithstanding shoote forth a new againe, and will hardly be destroyed where it hath once taken deepe rooting in the ground.

2. *Dens leonis angustioribus folijs.* Dandelion with narrow leaves.

This Dandelion is in all things like the other, but that the leaves are narrower, yet hath not fewer gashes or divisions on the edges, so that by this one note it may be distinguished.

3. *Dens leonis tenuissimo folio.* Fine jagged Dandelion,

This Dandelion hath a thicke reddish roote full of fibres, sending forth sundry most finely cut very greene leaves, each of a hand breadth long and two inches broad, deepely jagged, and divided againe into two or three other small rents or divisions, ending in a fine small point: the flowers are much smaller that stand at the tops of naked stalkes and yellow, turning into downe as the other.

4. *Dens Leonis minor radiatis folijs sive Trinciatella Italorum Camerarij.* Sweete Dandelion.

This sweete Dandelion (called by *Camerarius Trinciatella Italorum*, hath many leaves spread on the ground of three inches long and halfe an inch broade, cut in on the sides into sundry deepe gashes, whose ends have each of them three very deepe dents, and each having divers points standing like a starre or spurre, the foote stalke, whereof are a little hairy, among which rise up many smooth slender naked stalkes, one whereof standeth upright scarse an hand breadth high, the rest are lower and bend downewards, each of them bearing a small yellow

1. *Dens leonis vulgaris.*
Common Dandelion.

6. *Dens leonis Monspalienſium ſive Aſphodeli bulbulis.*
Bulbed or clogged Dandelion.

flower

ower like unto other Dandelions turning into downe, and flying away with the wind carrying the ſeede with it, which is ſomewhat long and broad with hard haires like beardes at the tops: the roote is ſmall and blackiſh without and white within, very ſweete in taſte as the leaves are alſo, and ſo tender to keepe that it periſheth with the firſt cold it feeleth: and muſt therefore be houſed, which then will endure many yeares giving ſeede yearely.

5. *Dens leonis minor aſpero folio.* Small rough Dandelion.

The ſmall rough Dandelion ſendeth forth ſundry ſmall leaves lying round about the roote of two or three inches long and one inch broade, divided or torne in on the ſides, each of them ſet with ſmall ſmooth ſharpe prickes or haires like as the prickly Sowthiſtle hath: the ſtalkes are about two inches high, and beare each of them a large pale yellow flower like the reſt and turned into downe: the roote is ſmall and whitiſh.

6. *Dens leonis Monſpelienſium ſive Aſphodeli bulbulis.* Bulbed or clogged Dandelion.

This Aſphodell rooted Dandelion ſpreadeth many large and blewiſh greene hairy leaves upon the ground unevenly waved or cut in on the edges but not deepely gaſhed, as the common Dandelion is of a bitter and ſharpe taſte like unto it, from which riſe ſundry bare or naked ſtalkes with ſeverall flowers, at the toppes of them larger and more double than it, and of a paler yellow colour which paſſe into downe like the reſt: the rootes are ſundry long tuberous and ſlender clogges like unto thoſe of the Aſphodill but ſmaller, ſhorter, and more pointed at the ends.

7. *Dens leonis Gadenſis.* Dandelion of *Cadis* in *Spaine*.

This plant ſo like in face unto a little Dandelion hath made me contrarie unto others opinions place it in the ſame ranke with them. It hath a number of long leaves a ſpanne long or more riſing from a long white tender roote: the middle ribbe of the leafe is bare from the roote to the halfe length of the leafe, and then it hath many rents or cuts on each ſide, very much reſembling the leafe of the ordinary Dandelion but ſmaller and narrower: the flowers likewiſe ſtand upon long foote ſtalkes as the Dandelion doth being ſmall and yellow, and doe turne into downe that is carried away in the winde, with the ſeede which is ſmall long, and reddiſh like unto ſome of the Hawkeweedes. It groweth in the Iland of *Gades*, which wee call *Cales* or *Cadis* as *Guillaume Böel* ſaith, who brought it us out of *Spaine*, and called it *Cichorium Gadenſe*: *Cluſius* it ſeemeth not well marking the plant being drie, and never having ſeene it greene or growing, tooke it from *Böel*, and calleth it in his *Curæ poſteriores Cichorium ſylveſtre pumilum ſive Hedipnois*, and ſaith it is altogether like unto it though leſſe: but how like it is, upon this deſcription truely ſet downe as before, I leave it to any judicious to determine. It flowreth in *July*, *Auguſt* and *September*, and the ſeede is ſoone ripe after the flower is paſt; the roote liveth all the Winter if it be milde, or elſe it periſheth with the hard froſtes.

The Place.

The firſt is too frequent in all medowes and paſture grounds, but the ſecond is more rare, yet often to be met with: the third groweth in *Auſtria*: the fourth in *Italy* as it is ſuſpected, becauſe it came from thence: the fift and ſixt about *Mompeliar*, as alſo about *Florence*, and in other parts of *Italy* eſpecially the ſixt, and the laſt in *Spaine*.

The Time.

They flower in the Summer moneths, yet as is well knowne the firſt is found in ſome place or other in flower every moneth in the yeare.

The Names.

The Dandelion is not certainely intituled by any Greeke denomination, for it is certaine it is not χονδρίλλη *Chondrilla*: but hath divers Latine names, as *Dens leonis*, *Urinaria*, *Corona* and *Caput monachi*, *Roſtrum porcinum*; and as *Anguilara* thinketh *Chrondrilla Galeni*: the firſt is uſually called of moſt of the later writers *Dens leonis*, but *Tragus* tooke it to be *Hieracium majus*, and *Cordus in hiſtoria*, to be *Hieracium parvum*; *Geſner in hortis Hieracium minus*, *Thalius* and *Dodonæus Chondrilla altera*, and *Cæſalpinus* (as divers others alſo doe) to be the *Aphaca* of *Theophraſtus*, *in lib. & cap.* 7. and 10. among the Wortes: divers alſo take it to be *Hedypnois Plinij lib.* 28. *c.* 8. but the moſt judicious rather take the former *Cichorium luteum* to be it: *Fuchſius* calleth it *Hedypnois major*, and *Lugdunenſis Hedypnois Dalechampij*; *Lonicerus* calleth it *Taraxacon minus*, and is generally held to be the true *Taraxacon* of *Serapio* and *Avicen*, and ſo uſed with us in all compoſitions whereunto *Taraxacon* is appointed: the ſecond *Cæſalpinus* calleth *Aphaca anguſtioris folij*: the third is called by *Columna Hieracium fœtidum*: and *Camerarius* calleth the fourth *Trinciatilla*: the fift is alſo of *Bauhinus* mentioned by the name in the title: the ſixt is called by *Matthiolus Cichorium Conſtantinopolitanum*, becauſe, as hee ſaith, hee received it from *Angerius de Busbeque* the Emperours agent at *Conſtantinople*; but *Lobel* and *Pena* ſay that hee needed not to extoll this plant as a ſtranger, being to be had plentifully in his owne country of *Siena* and *Tuſcane*, *Liguria* and other places of *Italy* whereof he was ignorant, as alſo about *Mompelier*, whereupon they called it *Dens leonis Monſpelienſium Aſphodeli bulbulis*, and withall ſuppoſe it to be the *Chondrilla altera Dioſcoridis*, or *Perdion* (rather *Perdicion*) of *Theophraſtus*; which hath more rootes than leaves: *Tabermontanus* calleth it *Dens leonis altera*; the laſt is mentioned ſufficiently in the deſcription: the *Italians* call *Dandelion Dente de leone*; the *Spaniards Diente de leon*; the *French Dent de lyon* and *Piſſe en lict*; the *Germanes Pfaffenblat*, *Korlkraut* and *Pfaffenrorlin*; the *Dutch Papencruyt Houtsrooſen* and *Canckerbloemen*; and we in *Engliſh* Piſſe a bed and Dandelion.

The Vertues.

Dandelion is neare in propertie unto the wilde Succory, and by the bitterneſſe doth more open and cleanſe, and is therefore very effectuall for the obſtructions of the liver, gall and ſpeene, and the diſeaſes that ariſe from them, as the jaundiſe and the *hypochondriacall* paſſion, it wonderfully openeth the uritorie parts, cauſing abundance of urine, not onely in children whoſe meſeraicall veines are not ſufficiently ſtrong to containe the quantitie of urine drawne in the night, but that then without reſtraint or keeping it backe they water their beds, but in thoſe of old age alſo upon the ſtopping or yeelding ſmall quantitie of urine; it alſo powerfully cleanſeth apoſtumes and inward ulcers in the uritorie paſſages, and by the drying and temperate qualitie doth afterwards heale them, and for thoſe purpoſes the rootes being buried a while in ſand and whited (which taketh away much of the bitterneſſe, and maketh them the more tender) being eaten as a ſallet are more effectuall than the leaves uſed in the ſame manner, or who ſo are not accuſtomed to ſuch raw ſallets may take the decoction of the rootes or leaves in white wine, or the leaves chopped as pot herbes with a few Alliſanders boiled in their broth. And who ſo is macilent drawing towards a conſumption, or hath an evill diſpoſition of the whole body, ready to fall into a *Cachexia* by

the uſe hereof for ſome time together ſhall finde a wonderfull helpe, not onely in clenſing the malignant humor but ſtrengthening the good, and preſerving the body ſound in all his functions: it helpeth alſo to procure reſt an ſleepe to bodies diſtimpered by the heate of ague fits or otherwiſe: the deſtilled water alſo is effectuall to drink in peſtentiall fevers and to waſh the ſores.

CHAP. XXVII.

Chondrilla. Gumme Succory.

IN *Dioſcorides* time there were but two ſorts of *Chondrilla* knowne, both which are much contro verted in our time, divers herbes being aſſimilated unto them, and ſcarſe any agreeing in all thing with them, but this age hath found out ſundry plants, which for the reſemblance are refer red to *Chondrilla*, and called by that name, whereof ſome beare blew flowers, and divers yellow Of thoſe with yellow flowers I ſhall entreate in this Chapter, and of the other in the next.

1. *Chondrilla prior Dioſcoridis legitima Cluſij.*

The former true Gumme Succory of *Dioſcorides* according to *Cluſius* his minde.

This Gumme Succory hath many long and ſomewhat broad hoary leaves lying upon the ground covered witl a thicke downe, cut in on the edges ſomewhat like thoſe of Succory, from among which riſeth up an hoary ſtalke a foote high or more parted into a few branches with ſmaller and narrower leaves ſet without order, whereor are ſometimes found yellowiſh graines like unto ſmall peeces of Gumme, which grow quickly to be hard: at th toppes of the branches ſtand ſingly yellow flowers like thoſe of Camomill, which when they are ripe turne int downe, and with the ſeede is carried away with the winde: the roote is of a fingers thickneſſe blackiſh on th outſide with ſome fibres thereat, and parted at the toppe into ſome heads, which bring forth leaves, &c. it is ful of juyce which is yellowiſh when it is drie.

2. *Chondrilla viminalibus virgis.* Gumme Succory with twigge-like branches.

This twiggy Gumme Succory ſhooteth forth ſundry ſlender tough and flexible branches or twigge-liki ſtalkes very clammy in handling, ſet with many narrow and ſhort leaves, but thoſe that grow at the foote of th ſtalkes next the ground are larger and longer, cut in on the ſides into divers long gaſhes, when thoſe ſtalkes grov toward flowring, the greater leaves begin to wither and die, ſo that being in flower they are quite gone and wi thered; the toppes whereof are furniſhed with ſmall yellow flowers, which in time turne into downe and paſſ away with the winde: the roote is long and ſlender, full of milke as all the reſt of the plant is if any part b broken.

3. *Chondrilla vimínea viſcoſa Monſpeliaca. French* twiggye Gumme Succory.

This *French* kind of Gumme Succory hath a white round ſtraked clammie ſtalke two cubits high, ſpreading int

1. *Chondrilla prior legitima Dioſcoridis.*
The former true Gumme Succory according to *Cluſius* his minde.

2. *Chondrilla viminalibus virgis.*
Gumme Succory with twigge-like branches.

divers

4. *Chondrilla viſcoſa humilis.*
Clammy dwarfe Gumme Succory.

5. *Chondrilla ſaxatilis viſcoſo caule.*
Galens Gumme Succory.

divers clammy branches pliant and eaſie to bend, whoſe leaves at the bottome are ſmooth like Willow leaves of ſixe inches long, and halfe an inch broad, ſometimes having a gaſh or two on them, but thoſe that grow up higher are ſomewhat like unto the lower leaves of the laſt Gumme Succory divided into many and very fine parts: the flowers are ſmall and yellow like the laſt which paſſe into downe and are blowen away, the roote is long and yellowiſh on the outſide.

4. *Chondrilla viſcoſa humilis.*
Clammy dwarfe Gumme Succory.

This low Gumme Succory ſendeth forth from a ſmall long white roote ſundry ſlender rough clammy, and bending ſtalkes about a foote high with a few long and narrow leaves without any dent thereon, eſpecially from the middle upward, where at the joynts with the leaves ſtand ſeverall ſmall long and yellow flowers turning into downe like the reſt, but the lower leaves, and thoſe on the lower part of the ſtalke are long and narrow, ſome whole without any dent, and others with one or two on the ſides.

5. *Chondrilla ſaxatilis viſcoſo caule.*
Galens Gumme Succory.

This rare Gumme Succory (which as *Columna* ſaith was not ſet forth before) hath a long roote ſo faſt ſet on the rocke where it groweth, that without breaking the rocke it cannot be got out, and being broken yeeldeth ſtore of thicke viſcous milke as every part elſe of the plant doth, which will hardly be waſhed off where it ſticketh to the hands, &c.

6. *Chondrilla Bulboſa.*
Bulbed Gumme Succory.

and quickly groweth into hard graines: the leaves are many that grow below, and are very much torne on the ſides into many deepe and crooked gaſhes like unto Dandelion: it ſeldome hath more than one ſtalke, and ſeldome alſo any branch, which is ſlender white and round, about a cubite high, ſet from the middle upward with long and narrow leaves not cut in or dented at all but parted at the bottome where it compaſſeth the ſtalke, and the moſt part of the length of the leafe cleaving thereto, that almoſt none of the ſtalke can be ſeene being as a hoſe or buskin thereon (which cauſed *Columna* to give it the name of κνημοδόρτιν) at the joynts with the leaves come forth

forth two or three or more flowers in long huskes, with ſhort footeſtalkes, yellow on the inſide and whitiſh without, flowring by degrees, ſo that ſome will be ripe and blowne away when others are new blowne or in the bud: the taſte hereof is bitter: the upper part hereof in the forme of the flowers and poſture of them is very like unto the wilde Lettice, whereunto *Galen* reſembleth *Chondrilla lib. 2. alimentorum*, and ſo may be referred to his *Chondrilla* or that of *Dioſcorides* for it hath ſome reſemblance with each.

6. *Chondrilla bulboſa.* Bulbed Gum Succory.

The bulbed Gum Succory hath divers ſmall leaves leſſer then Succory, with ſmall diviſions on the ſides ſet upon ſlender ſtalkes, among which ſpring up many ſlender weake ſtalkes on them, and at the toppes of each, one ſmall yellow flower like unto Dandelion which turneth into downe as the reſt: the rootes are divers ſmall round and bulbous, cleare, and of a purpliſh white colour, every one faſtned to the head with a long ſtring: the whole plant both roote and leafe is of a bitter taſte.

7. *Chondrilla bulboſa Syriaca anguſtifolia.* Bulbed Gum Succory of *Syria*.

This *Syrian* plant hath many long graſſelike leaves lying upon the ground, among which riſe divers ſmall ſtalkes ſet with ſmall leaves, from the joynts whereof breake forth ſmall branches bearing one flower a peece, which is large double and yellow like unto the great Mouſeare: the roote is as big as ones little finger at the head, and about a ſpan long growing ſmaller downewards ſmooth and of a browniſh yellow colour, having a ſmall round bulbe hanging at the end thereof of the bigneſſe of a Cheſnut, full of milke being never ſo little touched or broken.

8. *Chondrilla bulboſa Syriaca altera latiore folio.* Another *Syrian* bulbed Gum Succory.

This other Succory is both in roote and flower altogether like the laſt but differing onely in the leaves which are broader, more hairy and of a grayer colour.

The Place.

The firſt *Cluſius* ſaith he found in divers places of *Spaine* in waſt places: the ſecond he ſaith he not onely found in the Corne fields about *Salamanca* in *Spaine*, but in divers places of *Germany* and *Hungarie*: the third is found by the way ſides, and about *Mompelier* in Mount *Lupus*: the fourth about *Baſſile* in *Switzerland*: the fift upon the Rockes in the Kingdome of *Naples*: the ſixt not onely under the hedges about *Naples*, and in the wayes from thence to *Puteoli*: but towards the Sea ſide about the Fiſhermens cottages in *Narbone*, and the low Marſhes of *Mons Catus* and thereabouts: the two laſt *Rauwolfius* in his Peregrination found about *Aleppo* in *Syria* the one in the plowed fields and the other in ſtony places.

The Time.

All theſe ſorts of Succory doe flowër later then the reſt, many of them not untill *Auguſt* in their naturall places, and are ſo tender that they quickly periſh with the cold of theſe colder climates.

The Names.

Gum Succory is called in Greeke χονδρίλλη *Chondrilla*, ſo called as it is thought from χόνδρος which ſignifieth that drop or Gum-like Maſticke that groweth upon the herbe and ſtalke hereof, originally taken from the likeneſſe with that kind of graine prepared for pultage which was uſed in auncient times, called *Chondrus* or *Alica*, as I ſhall ſhew you more fully in the proper place, when I come to ſpeake of Cornes and the ſeverall ſorts of Pultage and Ptiſanes the ancient times made of them: ſome ſaith *Dioſcorides* called it *Cichorion* and ſome *Ieris*, and for that the leaves were like unto Succory, they accounted it a kinde of wilde Succory. The firſt is taken by *Cluſius* and others ſince him for the true *Chondrilla prima Dioſcoridis* and calleth it *Chondrilla prior Dioſcoridis legitima* (*Bauhinus* and divers others doe account *Matthiolus* his *Chondrilla prior* to bee but *figmentum ex Cichorio*, but I verily beleeve that it is *Cichoreum luteum*, for *Matthiolus* expreſſeth not the colour of the flower, and I am ſure the Figures are tranſpoſed or miſſet, for the firſt Figure anſwereth the ſecond deſcription, and the ſecond Figure to the firſt deſcription, which *Lacuna* it ſeemeth well obſerved in making that his firſt which in *Matthiolus* is the ſecond) *Lobel* and *Lugdunenſis* from him doe call it *Chondrilla verrucaria* but as I have ſhewed in the deſcription of *Cichorium verrucarium*, he mingled this and that together, *Tabermontanus* calleth it *Chondrilla Græca*, and *Bauhinus Chondrilla foliis Cichorei tomentoſis*: the ſecond *Cluſius* calleth *Chondrilla viminalibus virgis*, and *Lobel Chondrilla viminea viſcoſa vinearum*, *Cordus* upon *Dioſcorides Chondrilla altera*, *Dodonæus Cichorium ſylveſtre luteum*, *Cæſalpinus Chondrillæ ſpecies in collibus & vicinis*, *Tragus Cichorea procera vel quinta*; *Columna* taketh it to be *Chondrilla prior Dioſcoridis* as *Bauhinus* doth alſo, and withall thinketh it to be *Aphaca* of *Theophraſtus*, *Tabermotanus* and *Gerard* call it *Chondrilla Iuncea*: the third is called by *Bauhinus Chondrilla viminea viſcoſa Monſpeliaca*: the fourth alſo from *Bauhinus* taketh the name of *Chondrilla viſcoſa humilis*: the fift *Columna* ſo calleth as it is in the Title: the ſixt is called by *Lobel Chondrilla puſilla marina lutea bulboſa*, and may be as he ſaith *Perdion* of *Theophraſtus* (but rather *Perdicion*, *lib. 1. cap. 11.* for *Perdion* is not read in him) of *Cluſius Chondrilla altera Dioſcoridis* and ſo doth *Columna*, by *Cæſalpinus Herba terræ crepolæ ſimilis*, by *Caſtor Durantes Hemorrhoidale*, *Lugdunenſis* ſetteth it forth by the name of *Cichorium bulboſum Dalechampij*, and of *Cichorium ſtrumoſum Myconi* as *Bauhinus* thinketh: but I rather take *ſtrumoſum* to be that ſort of *Chondrilla* which *Rauwolfius* found in *Syria* with the larger leaves and is the laſt here expreſſed which *Bauhinus* calleth *Chondrilla bulboſa Conyſæ facie*, and referreth the *Conyza marina* of *Lugdunenſis* thereunto, wherein he is much miſtaken in my judgement, for that *Conyza* hath no ſuch bulbous roote, which cauſeth a great difference, beſides the difference in the heads of flowers: *Cluſius* from *Imperatus* of *Naples* ſaith that they about *Naples* call it *Herba dilatte*, and account it to bee *Scrophularia minor*, *Pandectarius* calleth it *Stridula*. The *Arabians* call *Chondrilla Candarel Cadaron*, and *Amiron*, the *Italians Condrilla*, and *Terra crepola*, the *Spaniards Leitugas* and *Leichagas dentro los planos*, but *Cluſius* ſaith they call it *Yerva di S. Guiteria*, and that by the ſame name they call *Phyllum*, and that they call the ſecond *Condrilla Iunqualina* and *Ajunjera*, the *French Leitteron*, the high and low *Dutch Condrille*, and we in *Engliſh* Gum Succory, becauſe of the Gum is found upon it.

The Vertues.

Gum Succory is of the ſame propertie with wilde Succory but more bitter and more dry, and is thereby the more effectuall in opening obſtructions, and by the drying qualitie ſtayeth the looſeneſſe of the belly, if the juice of the roote be taken in wine: the Gum uſed with Myrrhe in the forme of a peſſarie draweth downe womens courſes that are ſtayed, the juice of the roote or the herbe and roote together made into powder and drunke in wine,

wine, helpeth the biting of the Viper and all other venemous Serpents, and deſtroyeth field miſe alſo: *Pliny* writeth that one *Dorotheus* in his verſes ſheweth that it is beneficiall to the ſtomacke, and helpeth digeſtion, and further ſaith that ſome did account it hurtfull to the eyes and to hinder generation both in men and women, and yet he numbreth *Chondrilla* among other ſallet herbes that were uſed to bee eaten: the juice of the herbe but more effectually of the roote dropped from the point of a needle or other ſuch ſmall thing, taketh away by the rootes the ſuperfluous haires of the eyebrowes, the ſame alſo uſed with a little niter cleanſeth the skinne from all freckles, morphew, ſpots or any diſcolouring thereof. The bulbous Gum Succory is much commended againſt the ſwellings and kernells of the throat called the Kings Evill, and ſo is the diſtilled water thereof: the rootes preſerved are found to be wonderfull effectuall, if the uſe be continued for ſome time together.

CHAP. XXVIII.

Chondrilla purpurea. Purple Gum Succory.

THere are other ſorts of Gum Succory to be entreated of, differing from the former in many notable parts as well as in the flowers which are quite of another hew, as ſhall be ſhewed in this Chapter.

1. *Chondrilla cærulea ſive purpurea.* Purple flowred Gum Succory.

This Gum Succory ſhooteth forth in the beginning of the Spring ſundry long winged or rather jagged leaves, conſiſting of many long and narrow jagges, cut in on both ſides to the middle ribbe, and equally almoſt ſet one againſt another of a blewiſh greene colour very tender and full of milke being broken, among which riſe up weake and tender ſtalkes three or foure foote high, ſcarſe able to ſtand upright, very brittle alſo and apt to be broken, as full of milke as the leaves, which divideth it ſelfe towards the toppes into a few other ſmaller branches, with ſmaller and leſſe jagged leaves upon them, and ſmall blewiſh purple flowers at the ends and ſometimes white, conſiſting of ten or twelve ſmall narrow leaves ſtanding round about the middle, which when they are ripe fall away of themſelves: the rootes grow deepe downe and ſpread into many corpulent branches like Dandelion, blackiſh on the outſide and yeelding much milke in every part that is broken, which are ſo apt to grow that every little peece in the ground will ſpring againe and beare leaves, &c.

2. *Chondrilla cærulea latifolia.* Purple Gum Succory with broader leaves.

This other Gum Succory is very like unto the former in all things, but that the leaves are ſomewhat ſhorter and broader, and the gaſhes alſo larger wherein cheefely conſiſteth the difference.

3. *Chondrilla purpuraſcens fœtida.* Stinking Gum Succory.

The ſtrinking Gum Succory hath divers long and ſomewhat narrow leaves growing next to the ground ſome being waved or torne ſomewhat deepely on the edges, the footeſtalkes being ſometimes reddiſh, in the middle of whom riſeth up ſundry browne ſtalkes a little hairy, and about a cubit high, having but very few branches and

1. *Chondrilla cærulea ſive purpurea.* Purple flowred gum Succory.

2. *Chondrilla cærulea latifolia.* Purple gum Succory with broader leaves.

they bare or naked of leaves from the joynts to the toppes, where every one of them ſuſtaine a flower conſiſting of ſixteene ſmall leaves or more, dented at the edges, of a purpliſh red colour compaſſing the middle, wherein afterwards are conteined long browniſh ſeede lying in downe, which together are blowne away with the winde, the roote hereof periſheth every yeare after ſeede time, but recovereth it ſelfe by the fallen ſeede, the leaves as well as the flowers have a ſtrong unpleaſant ſent.

3. *Chondrilla purpuraſcens foetida.*
Stinking gum Succory.

4. *Chondrilla rara purpurea Crupina Belgarum dicta.*
The bearded Creeper.

I have two other plants to ſhew you which have paſſed by the names of *Chondrilla*, either of which hath ſmall affinitie with them as I thinke, onely excepted by *Columna*. yet give me leave to inſert them in this place, although I ſhew you my mind of them. This firſt hath the firſt leaves that ſpring up, nothing ſo much cut in or divided as the others that follow, but rather ſomewhat reſembling the leaves of Groundſell, and are roughly dented about the edges, the next are very much cut and divided into many ſmall parts ſomewhat rough or hard in handling, and ſomewhat ſharpe at the points of the cuts, from among which ſpring ſundry ſlender whitiſh and hairy ſtalkes about a foote and a halfe high, with two or three branches and ſmaller but not leſſe divided leaves upon them to the toppes, where ſtand three or foure flowers in ſcaly heads, the points whereof are purpliſh, conſiſting of five leaves, of a purpliſh blew colour as the border, and many purpliſh thrums in the middle, ſome whitiſh threads alſo in the midſt: the ſeede that followeth incloſed in the heads is like the ſeede of a Iacea or Knapweede or Matfellon but ſomewhat greater blacke and ſhining, with divers ſtiffe ſtaring haires like a beard at the head

5. *Chondrilla Seſamoides dicta.*
Strange gum Succory.

of every one, which will not abide or be ſtill either in ones hand or in paper, &c. if it be never ſo little ſtirred, but will as it were creepe or thruſt it ſelfe forwards by the ſtiffe haires (whereupon I have given it the *Engliſh* name as it is in the title) the roote is long and white and periſheth every time it beareth ſeede, yet abideth the firſt Winter after it ſpringeth in the Autumne, for it hardly abideth a Winter if it riſe in the Spring although it doth neither flower nor ſeede.

5. *Chondrilla Seſamoides dicta.* Strange Gumme Succory.

This other plant referred, as I ſaid, to the *Chondrillaes*, hath many long and narrow rough leaves, pointed at the ends, and jagged in two or three places on the edges, ſometimes more or leſſe lying on the ground, reſembling very much, the leaves of *Coronopus* or Bucks horne Plantane, but with fewer greater and longer cuts or jaggés, the branched ſtalkes are ſet from the middle of them, with ſuch like leaves, but narrower, ſome without any jagge, and ſome but with one or two, bearing at the toppes every one upon ſlender bare long ſtalkes, a ſmall whitiſh ſilver-like ſcalyhead, out of which breaketh forth faire double flowers conſiſting of many purpliſh blew leaves dented or cut in at the broad ends, with ſome yellow threads in the middle of them (*Matthiolus* hath very badly ſet this forth with the heads of *Phalaris Canary* graſſe) after which commeth ſmall ſeed like unto *Seſamum*, as it is compared, and from thence tooke the name of *Seſamoides*, but as I thinke more fitly unto a *Cyanus* Corne-flower or Blew-bottle but browner: the roote is ſmall and long, yeelding a milke: both theſe plants may in my mind be better referred to the *Jaceas* than unto any other herbe, they doe in leaves not much varie, nor yet in heads and flowers, but in ſeede eſpecially come neareſt thereunto, and not unto the *Chondrillaes*, whoſe ſeede is much differing having downe on the heads of them, and flie away together with the winde.

The Place.

The firſt (as well as the ſecond, for I account them both as one) groweth, as *Matthiolus* ſaith, in many places of *Italy*, as well as *Tuſcane* in waſt grounds, by ditch ſides, and the way ſides in fields and paſtures; and as *Cordus* ſaith in the Vineyards about *Gena*: the third *Bauhinus* ſaith he onely ſaw in *Zuingerus* garden and his owne: the fourth in *Spaine Narbone* in *France*, and *Naples* alſo: the laſt is not certainely knowen from whence is the originall but is nurſed up in gardens.

The Time.

They doe all flower in the Summer moneths, and yeeld their ſeede ſoone after.

The Names.

They are all accounted *Chondrillæ ſpecies* by divers, whereunto for the former three I may well agree being in face not much differing from wilde Succory; the firſt being called by *Lobel Chrondrilla cærulea Belgarum*, by *Donæus Chondrilla altera*, by *Cordus* upon *Dioſcorides Chrondrilla prima Sichorio ſimilis*, and in his Hiſtory *Chondrilla tenera*; by *Camerarius Chondrilla cærulea flore*; who ſaith the *Italians* call it *Caccia lepore*; *Lugdunenſis* maketh it to be *Apate Dalechampij*, and ſaith the *Italians* call this *Terra crepola*, by *Tabermontanus Chondrilla cærulea* and *alba*, as *Cordus* before him did; *Gerard* giveth two figures hereof, which *Bauhinus* noteth, and calleth this firſt *Chrondrilla cærulea altera Cichorij ſylveſtris folijs*: the ſecond is that which *Matthiolus* ſetteth forth as an *hyſteron proteron*, as I ſaid before, calling it *Chondrilla altera*, and *Lacuna Chondrilla prima*, obſerving, as it is likely his errour, and by *Bauhinus Chondrilla Cærulea latifolia laciniata*: the third *Bauhinus* mentioneth in his *Phytopinax*, *Pinax* and *Prodormus* by the name of *Chondrilla purpuraſcens fœtida*, and *Beſler in horto Eyſtetenſi Chondrilla rubra fœtida*: the fourth is called by *Lobel Chondrilla rara purpurante flore ſemine nitido deciduo*, and *Crupina Belgarum*, and findeth fault with his owne miſtaking in calling it formerly *Superba recentiorum*; wiſhing it to be blotted out: *Lugdunenſis* calleth it *Chondrilla purpurea Lobelij*, and *Tabermontanus Chrondrilla Hiſpanica Narbonenſis*: *Columna* finding it in *Naples*, could not well tell to what *genus* he might referre it, and therefore called it *Senetio Carduus Apulus*; and *Bauhinus* to varifie his title from all others, calleth it *Chondrilla foliis laciniatis ſerratis, purpuraſcente flore*: the laſt is but one ſort, although *Bauhinus* maketh it to be two, becauſe *Camerarius* firſt ſet forth the plant with the flower ſpread open that it might be the better knowne, yet is the ſame that *Matthiolus* calleth *Seſamoides parvum*, not rightly expreſſed, and from him *Caſtor Durantes*, *Camerarius*, *Tabermontanus* and *Columna* doe ſo enttile it, yet *Columna* thinketh it may be *Cyanus Plinij*. *Lobel* calleth it *Seſamoides parva Dioſcoridis*, but *Geſner in collectione ſtirpium Coronopus quidam flore cæruleo*, *Dodonæus* maketh it his *Chondrilla tertia ſpecies* & *Lugdunenſis Catanance quorundam*: *Bauhinus*, as I ſaid, to make two ſorts hereof entituleth his firſt *Chondrilla cærulea Cyani capitulo*, and the other (which as I ſaid *Camerarius* in his *Matthiolus* ſetteth forth, with the title of *Seſamioides parvum flore magis completo*, and *Eſtetenſis Chondrilla Seſamoides dicta cæruleo flore completo*) *Chondrilla cærulea Cyani capitulis altera*. *Cordus* ſaith that the *Germans* call this firſt *Choudrilla Klein Sonnen werbel*, and as is ſaid before, the *Italians Caccia lepore*, and ſome *Terra crepola*.

The Vertues.

Matthiolus ſaith that the people in *Italy* where the firſt ſorts doe grow doe eate them in their ſallets as Succory is, being accounted of the ſame propertie, but I have no other Author that giveth any ſpeciall inſtance of the vertues therein, and therefore you may as I referre them to the kindred of the Succories, and be perſwaded of the like effects to be found in them, neither have I any more certainty to ſpeake of the reſt.

CHAP. XXIX.

Hieracium. Hawkeweeke.

TO ſet forth the whole family of the Hawkeweedes in due forme and order, is ſuch a world of worke, that I am much in doubt of mine owne abilitie, it having lyen heavie on his ſhoudiers that hath already waded thorough them, and will be as heavie to me, although he be a guide for me to follow: If I therefore (as he before me no doubt hath done) ſlippe or goe awry, let it be pardoned in me, as it muſt be in him, or let them that too critically find fault amend it by aſſured knowledge if they can themſelves, and I will give them thankes. For ſuch a multitude of varieties in forme pertaining to one herbe is not to be found againe, *in rerum natura*, as I thinke. That I may therefore ſo ſet them forth, that ye may apprehend them rightly, as I ſhall endeavour to expreſſe them aptly and methodically, I muſt diſtribute them into

into ſundry formes and orders after ſuch a manner, as I thinke meete to diſpoſe them, and in ſeverall Chapters according as you ſhall finde by the titles at the heads of every of them.

Ordo primus. The firſt Ranke or Order.

Hieracia Dentis leonis folijs acuta. Sharpe pointed Dandelion-like Hawkeweedes.

1. *Hieracium majus Sonchites.* Great Hawkeweede with Sow-thiſtle leaves.

THis great Hawkeweede hath many large hairy leaves lying on the ground much rent or torne on the ſides into divers gaſhes and jagges, ſomewhaat like unto Dandelion, but with greater parts, more like unto thoſe of the ſmooth Sow-thiſtle, from among which riſeth a hollow rough ſtalke, two or ſometime three foote high branched from the middle upwards, whereon are ſet at every joynt, where it brancheth longer leaves, little or nothing rent or cut in, bearing at their tops ſundry pale yellow flowers, conſiſting of many ſmall narrow leaves broad pointed, and nicked in at the ends, ſet in a double row or more, the outermoſt being larger than the inner, which forme moſt of the Hawkeweedes doe hold in all the ſorts, which turne into downe and with the ſmall browniſh ſeede is blowne away with the winde: the roote is long and ſomewhat great with many ſmall fibres thereat; the whole is full of a bitter milke.

2. *Hieracium majus Creticum.* Great *Candy* Hawkeweede.

This *Candy* Hawkeweede hath the firſt leaves little or nothing dented, but ſomewhat like Endive, yet thoſe that follow are cut in on the ſides, not ſo much as the Sow-thiſtle, elſe not much unlike, which are more tender yet larger than the former as the ſtalkes are likewiſe, bearing on the branches greater huskes wherein the yellow flowers grow, which paſſe into downe with rough crooked ſeede lying therein, and are both diſperſed by the winde: the whole plant is bitter, and periſheth at the firſt approach of Winter being but annuall, and to be new ſowen every yeare.

3. *Hieracium magnum Hiſpanicum.* Great *Spaniſh* Hawkeweede.

This *Spaniſh* Hawkeweede hath a round hollow creſted ſtalke ſomewhat hairy, about a cubite high or more, whoſe bottome leaves are long and large like Dandelion, very much cut in and hairy on the edges, each being about a foote in length, and an inch and a halfe in breadth; thoſe on the ſtalkes are divided at the bottome into two parts like eares, compaſſing them about, as they grow higher they are leſſe jagged, and the higheſt a little waved onely at the edges; at the toppe of the ſtalke groweth a double flower like the Dandelion, and of the ſame bigneſſe, but of a paler yellow colour which paſſeth into downe as the reſt doe.

1. *Hieracium majus Sonchites.*
Great Hawkeweede with Sow-thiſtle leaves.

4. *Hieracium folijs & floribus Dentis leonis bulboſi.*
Bulbed Dandelion-like Hawkeweede.

Hieracium

4. *Hieracium asperum folijs & floribus Dentis leonis bulbosi.*
Bulbed Dandelion-like Hawkeweede.

The rough leaves of this Hawkeweede that lie upon the ground, are much cut in on the edges, like unto those of the bulbed Dandelion each rent or gash looking downeward to the bottome of the leafe, amongst which riseth up an hairy bare or naked stalke, bearing a large Dandelion-like yellow flower which turneth into downe, and is carried away with the winde: the roote is somewhat great and long with some fibres thereat.

5. *Hieracium Dentis leonis folio asperum.*
Rough Dandelion-like Hawkeweede.

This small Hawkeweede hath divers long and narrow hairy leaves, reddish at the bottome next the roote, deepely waved or torne on the edges, being about two inches long, from which rise one or two or more bare or naked stalkes rough or hairy, bearing each of them a double yellow flower like unto the Hawkeweedes passing into downe: the roote is small somewhat like a finger, with a few fibres hanging thereat.

6. *Hieracium minus glabrum.*
Small Hakeweede with smooth shining leaves.

This little Hawkeweede riseth little above a spanne high, with smooth fresh greene stalkes, branched forth into others, set with few, but smooth shining greene leaves long and narrow, being little torne on the edges, compassing the stalkes at the bottome, and eared as the third: the flowers that grow at the toppes are of a faire gold yellow colour, lesser than any other Hawkeweede, each standing on a foote stalke, about an inch long, which as the rest, doe passe away with the winde: the roote is small, long, and whitish.

7. *Hieracium hirsutum ferè umbellatum.*
Small Hawkeweede with umbel-like flowers.

This small Hawkeweeke hath five or sixe small leaves lying upon the ground, waved or cut on the edges like unto the common Hawkweede, having a soft downe like haires on the upper side of the leaves, and smooth without haires underneath full of a bitter milke, from among which riseth up a slender hairy stalke about a foote high or more, bearing at the toppe divers small flowers set together as it were in a tuft or umbell, of a gold yellow colour like in forme unto others, as also in the downie heades: the roote liveth long, being composed of many small white stringes, which shooteth forth and spreadeth it selfe also into many heads above ground, which shoote forth branches, rooting also in the ground as they lie.

The Place.

The first groweth in divers places about fields sides, and the path wayes in dry grounds: the second is of *Candy*: the third of *Spaine*: the fourth of *Italy*: the fift in our owne Land, as well as about *Mompelier*, *Naples*, and *Spaine*: the sixt about *Basil*: the last about *Vienna* in *Austria*.

The Time.

They doe all flower and flie away in the Sommer moneths.

The Names.

It is called in Greeke ἱεράκιον of ἱέραξ *accipiter* an Hawke, *Sic dictum volunt quod accipitres sibi hujus succo aciem oculorum acuere dicuntur* (as divers other herbes tooke their names, some from beasts as *Elaphoboscum a Cervo*; others from birds, as *Chelidonium ab Hirundine*, *Perdicion a Perdice*,) in Latine also *Hieracium*, and of some *Accipitrina*: and because they doe partake of Sow-thistles as well as of Succory, I have placed them betweene them both: the *Italians* call it *Hieracio*, the *French L'herbe d'espervier*, the *Germanes Hauks kraut*, the *Dutch Havickscruijde*, and we in *English* Hawkeweede, and of some yellow Succory: the first here set forth is the *Hieracium majus* of *Matthiolus*, *Fuchsius*, *Dodonæus*, *Lobel* and others, the *Taraxacon majus* of *Lonicerus*, *Intubus secundus* of *Tragus* as it is thought, and *Hieracium Sonchites* or *Sonchi folio* of divers, but of *Lugdunensis Hieracium minus*, because he setteth forth the *Chondrilla prior Dioscoridis* for *Hieracium magnum*, as I shewed you in the last Chapter save one: the second *Gesner* and *Camerarius* onely make mention of, the one *in hortis Germaniæ*, the other *in horto Medico*, by the name of *Hieracium Creticum pro Endivia lutea missum*, and there sheweth why hee called it *Creticum*, even because he found the like seede among *Epithymum* that came from *Candy*: the third *Bauhinus* setteth forth by the name of *Dens leonis latifolius arborescens*, saying it came to him out of *Signor Contarinos* of *Padoa* his garden, by the name of *Hieracium Hispanicum*; and therefore I have so called it, and placed it here, and not among the Dandelions, as hee doth in his *Pinax*: the fourth *Lobel* in his *Dutch* Herball, and *Icones* calleth *Hieracium folijs & floribus dentis leonis bulbosi*, because being very like it, yet differeth in the long roote: the fift *Bauhinus* maketh of two sorts, calling them *Hieracium dentis leonis folio hirsutie asperum magis laciniatum*, and *minus laciniatum*, but I thinke they are both one, and therfore doe not distinguish them; *Columna* calleth it *Hieracium aletrum saxatile montanum*: the sixt *Bauhinus* calleth *Hieracium minus glabrum*; and the last *Clusius* describeth for his ninth *Hieracium*, but the figure he setteth for it, is much differing from the description thereof, but answereth well the description of the eleaventh, and it may be was but the Printers fault in transposing the letter I, being set

before

before the X, that ſhould have beene ſet after, thereby making it XI. when it is ſet IX.

The Vertues.

Hakeweede, ſaith *Dioſcorides* is cooling, ſomewhat drying and binding, and therefore is good for the heate of the ſtomacke, and for inflammations, and the hot fits of agues and gnawings of the ſtomacke: the quantitie of a ſcruple of the dried juice, ſaith *Pliny*, taken in *Poſca* Poſſet, that is vinegar and water mixed purgeth the belly, yet he ſaith in another place, that a ſmall quantitie bindeth the belly: the ſaid juyce taken in wine helpeth digeſtion, diſcuſſeth winde, and hindereth any crudities to abide in the ſtomacke, it helpeth alſo the difficultie in making water: the ſame likewiſe taken in wine helpeth the bitings of venemous Serpents, and of the *Phalangium*, and the ſting of the Scorpion, if the herbe alſo be outwardly applied to the place; and helpeth alſo all other poyſons, except that of *Ceruſſa*, or thoſe that hurt the bladders or that kill by ſtrangling: a ſcruple of the dried juyce given in wine and vinegar, is profitable for thoſe that have the dropſie: the decoction of the herbe taken with hony digeſteth thinne flegme in the cheſt or lungs, and with Hyſſope, doth helpe the cough: the decoction thereof, and of wilde Succory made in wine and taken, helpeth the wind collike, and thoſe that are melancholike or have hard ſpleenes: it procureth reſt and ſleepe, it hindereth venery and venereous dreames, cooleth heates, purgeth the ſtomacke, encreaſeth bloud, and helpeth the diſeaſes of the reines and bladder. Outwardly applied it is ſingular good for all the defects and diſeaſes of the eyes uſed with ſome womens milke: it is alſo uſed with good ſucceſſe in fretting or creeping ulcers, eſpecially in the beginning: the greene herbe bruiſed, and with a little ſalt applied to any place burnt with fire before bliſters doe ariſe, doth helpe them, as alſo inflammations, Saint *Anthonies* fire, and all puſhes and eruptions of heate and ſalt flegme: the ſame applied with meale and faire water in manner of a pultis to any place affected with convulſions, and the crampe, or ſuch as are out of joynt doth give helpe and eaſe. The diſtilled water is of good uſe in many of the diſeaſes aforeſaid, and the face waſhed therewith clenſeth the skinne, and taketh away freckles or ſpots, the morphew and other blemiſhes in the skin, and helpeth to take away wrinckles in the face alſo. The fift is by the relation of Mr. *Iohn Morrice* Gentleman of *Iſſellworth* beyond *Braindford* unto mē by good experiments from others, ſingular good to helpe the Pleuriſie, onely by taking the juyce thereof in drinke.

CHAP. XXX.

Hieracia Dentis leonis folio obtuſo. Dandelion-like Hawkēweede with blunt pointed leaves.

Ordo ſecundus. The ſecond rankē.

1. *Hieracium longius radicatum.* Long rooted Hawkewēde.

THe leavēs of this Hawkewee that lie upon the ground are long and narrow much torne and jagged on the edges ſomewhat like unto Dandelion, but cut into many ſhort round pointed peeces, and of a darke greene colour, the ſtalkes that riſe from among the leaves are ſmooth and blackiſh ſcarce a foote high, bare or without leaves on them unto the toppes, but at the upper joint, from whence ſpring ſundry flowers each ſtanding on a long foote ſtalke, which are yellow like unto other Hawkeweedes and turne into downe as they doe: the roote is white ſmall and long, running downe as deepe into the ground, ſaith *Lobel*, as the ſtalke is high, that which I and many others have taken for it, have more and ſhorter rootes.

1. *Hieracium longius radicatum.* Long rooted Hawkeweede.

2. *Hieracium dentis leonis folio obtuſo minus flore magno.*

Small Dandelion-like Hawkeweede with round pointed leaves.

This ſmall Hawkeweede hath ſixe or ſeven thicke rough leaves lying on the ground, about two inches long, and halfe an inch broad, round pointed and jagged about the edges, after the faſhion of the former, but not with ſuch deepe jagges, among which riſeth a bare hollow ſmooth ſtalke, whereon is ſet a large pale yellow flower, which turneth into downe, the roote is ſmall and fibrous.

3. *Hieracium tomentoſum Hiſpanicum.*

Spaniſh woolly Hawkeweede.

This Hawkeweede hath divers hoary ſoft woolly leaves lying on the ground, cut in on the ſides like Dandelion, every one ſtanding upon a ſmall long foote ſtalke, being of three or foure inches long, and halfe an inch broad, the ſtalke is hoary likewiſe, and branched about a ſpanne high having ſmaller leaves thereon, with ſmaller diviſions, at the tops ſtand very yellow flowers on very ſhort foote ſtalkes, ſhooting out of very fine hoary huskes pointed at the brimmes with many points: the roote is white on the outſide.

4. *Hieracium dentis leonis folio floribus parvis.*

Dandelion Hawkeweede with ſmall flowers.

Thē roote hereof is ſmall, white, wooddy and fibrous, the ſtalke is round, a foote high, and ſomewhat hoary, at the bottome whereof grow a few rough leaves, bitten in, as it were about the edges, about three inches long, and halfe an inch broad, having but few leaves thereon and thoſe about the middle, which are but only dented and compaſſe it at the bottome, bearing many very ſmall yellow flowers together, upon very ſhort ſtalkes at the toppes thēreof.

7. *Hieracium media nigrum.*
Small blacke ſpotted Hawkeweede.

8. *Hieracium aſperum Hypocheris ſive Porcellio dictum.*
Swines Hawkeweede with rough leaves.

9. *Hieracium minimum Cluſij.*
Cluſius his leaſt Hawkeweede.

10. *Hieracium parvum Creticum.*
Small Hawkeweede of *Candy*.

5. *Hieracium dentis leonis folio bulboſum. Aſphodill* rooted Hawkeweede.

This Hawkeweede hath for the roote a few long clogges, like the *Aſphodill* roote, the ſtalke that riſeth from thence is about a cubite high, bare of leaves from the bottome to the middle, ſmooth and creſted, about the middle ſeparated into one or two branches, of a foote long apeece, each whereof ſuſtaineth a ſmall yellow flower like the others in this kinde, which paſſe away in like manner; the leaves that lie upon the ground are rough on the upperſide, and ſmooth with a certaine wollineſſe underneath, cut or torne on the edges very like unto Dandelion, being about three inches long and one broad.

6. *Hieracium medio nigrum Bœticum majus.* The greater blacke ſpotted Hawkeweede of *Spaine.*

This hath foure or five ſmall, long, and narrow ſmooth whitiſh greene leaves lying on the ground, bluntly cut in on the ſides, but not very deepe, the midde ribbe being whitiſh all the length thereof, from theſe ſpringeth up uſually but one ſmall ſtiffe whitiſh greene ſtraked ſtalke branched into ſundry parts, about a foote and a halfe high, with a few ſmaller leaves thereon at the joynts, and few or no dents upon them: the flowers grow at the toppes and from the joynts of the branches thicke and very double, but one on a head or joynt like a ſmall Hawkeweede, of a very pale yellow colour, with a blackiſh purple ſpot in the middle, which turne into very ſhort downe, that with the ſmall browne ſeede flieth away: the roote is ſhort and woddy periſhing every yeare that it ſeedeth.

7. *Hieracium medio nigrum Bœticum minus.* The ſmaller blacke ſpotted Hawkeweede of *Spaine.*

This is altogether like the laſt, both in ſtalkes, leaves, and flowers, with the like purple ſpot in the middle, but they are in every part three times ſmaller.

8. *Hieracium aſperum Hypocheris ſive Porcellia dictum.* Swines Hakeweede with rough leaves.

This ſmall Hawkeweede (rather than Succory, as *Gerard* calleth it, and his Corrector ſo letteth it paſſe) hath divers ſomewhat long and rough leaves lying on the ground, ſmaller at the bottome, and broader towards the end, unevenly waven at the edges: the ſtalkes are ſomewhat rough, ſlender, and bare of leaves branching into ſundry long ſtalkes, about halfe a foote high, bearing every one a large yellow flower like unto Hawkeweede: the roote is ſmall and long. There is another of this ſort, whoſe leaves are ſmooth and narrower, differing little in any thing elſe.

Hieracium glabrũ ſive Porcellia anguſtifolia.

9. *Hieracium Cluſij, Hyoſeris Tabermontani & Gerardi. Cluſius* his leaſt Hawkeweede.

This ſmall Hawkeweede of *Cluſius* hath divers ſmall leaves upon the ground, ſomewhat like unto Dayſie leaves but longer, and unevenly dented or waved about the edges, from whom riſeth up a ſtalke or two, or ſometimes more, halfe a foote high, naked, hollow, and reddiſh at the bottome, and ſometimes branched towards the toppe, reddiſh alſo at the joints, which grow bigger above than they are below, contrary herein to all, or moſt other plants, bearing on each of them a ſmall yellow flower like others, and turning into downe that is blowne away as the reſt. *Cluſius* maketh mention of another ſort hereof, was brought him by *Gulielmus de Mera*, a Phyſitian, whoſe flowers paſſed not into downe, but the ſeede being long and ſomewhat blackiſh, did ſtill abide in the heads.

Minimum alterum.

10. *Hieracium parvum Creticum.* Small hawkeweede of *Candy.*

This *Candy* Hawkeweede being an other ſort of the laſt deſcribed, hath divers leaves ſpread upon the ground, ſmaller at the bottome, and growing broader to the ends, cut in with a deepe cut or two where it is broadeſt, and all the reſt of the edges unevenly waved, the middle ribbe being reddiſh, from among which riſe two or three ſlender bare ſtalkes, about a foote high, branching forth into two parts, with a ſmaller leafe at the joynt, more divided than any below, bearing on each of them a larger flower than anſwereth well the proportion of the plant in forme like other Hawkeweedes, but pure white on the upper ſide, and of a bluſh colour underneath: the roote is long and ſmall with ſome fibres thereat.

The Place.

Divers of theſe Hawkeweedes grow abroad in the fields, waſt grounds, and lanes in divers places of our owne country, as well as in other; but the ſixth and ſeventh came to me from *Spaine.*

The Time.

They all flower and fall in the Summer time, and ſome abide untill the Autumne coldes cauſe them to periſh, and will riſe againe of their owne fallen ſeede.

The Names.

The firſt is called by *Lobel Hieracium longius radicatum*, and *microphyllon* by *Tabermontanus*; *Dodonæus* in his *French* Booke calleth it *Hieracium minus primum*, and *Lugdunenſis Apargia Dalechampij*, whereof *Theophraſtus* ſpeaketh, *l.* 7 *c.* 9 *inter* ἐπιφύλλια *ad terram folioſas plantas*; and *Bauhinus Hieracium dentis leonis folio obtuſo majus*: the ſecond *Bauhinus* calleth, as it is in the title, *Hieracium dentis leonis folio obtuſo minus flore magno*: the third he calleth *Hieracium tomentoſum Hiſpanicum* in his *Prodromus*, which hee omitted in his *Pinax*: the fourth hee doth likewiſe call *Hieracium dentis leonis folio floribus parvis*: the fift he calleth *Hieracium dentis leonis folio bulboſum*: the ſixt and ſeventh are as I ſaid *Hieracia* raiſed from the *Spaniſh* ſeede I received, and are the ſame that *Cluſius* mentioneth in his *Curæ poſteriores* without deſcription: the eight is the *Hypocharis ſive Porcellia* of *Tabermontanus*, & *Gerard*, which he putteth among the *Chondrillas*, & calleth it in *Engliſh* Swines Succory, as he doth the next hereunto Male Swines Succory, they being both certainely kindes of *Hieracium*, *Bauhinus* calleth it *Hieracium minus dentis leonis folio ſubaſpero* (and maketh ſome doubt or queſtion whether it ſhould not be the *Hieracium minimum* of *Columna*) and the other of this kinde *Hieracium minus dentis leonis folio oblongo glabro*, and is the *Hyoſeris altera vel anguſtifolia* of *Tabermontanus*: the ninth is the *Hieracium minimum* of *Cluſius*, the figure whereof is falſely quoted IX. for XI. and is the *Hyoſeris latifolia vel maſcula* of *Tabermontanus* and *Gerard*, which *Bauhinus* calleth *Hieracium minus folio ſubrotundo*: the laſt *Cluſius* ſetteth forth in his firſt *Appendix* that is joyned to his Hiſtory of plants, and is the laſt there by the name *Hieracium parvum Creticum*, which *Bauhinus* calleth *Hieracium minus flore albo carneo*. *Pona* in his *Italian* Booke of *Mount Baldus*, calleth it *Hieracium intubaceum non ramoſum.*

The Vertues.

All theſe ſmall Hawkeweedes, or the moſt of them, being of the like bitter qualitie to the former, doe no doubt performe the ſame effects, although peradventure in a weaker manner: but becauſe I have not any peculiar propertie

properties to relate of any of them, I referre you to the former Chapter to be informed of their qualities, and to what diſeaſes they may be conducible.

CHAP. XXXI.

Hieracia Chondrillæ foliis. Gumme Succory-like Hawkeweedes.

Tertius Ordo. The third Ranke.

1. *Hieracium maximum aſperum Chondrillæ folio.*
The greateſt Gumme Succory-like Hawkeweede.

1. *Hieracium maximum aſperum Chondrillæ folio.*
The greateſt Gumme Succory-like Hawkeweede.

THis great Hawkeweede hath a great round rough ſtraked ſtalke, bigger in one place than another, almoſt three foote high, branched towards the toppe into ſhort branches, with great long leaves ſet there-on one above another, much torne in on both ſides, to the middle ribbe almoſt, about three inches long, very hairy and rough in handling: the flowers are great and yellow like unto other Hawkeweedes.

2. *Hieracium folijs & facia Chondrillæ Lobelij.*
Lobel his Gumme Succory-like Hawkeweede.

This kinde groweth not ſo high as the former, and hath the leaves thicker jagged, but not ſo large, each jagge ſomewhat dented alſo and ſomewhat hairy: thē flowers are yellow, but not ſo thicke or double, but more growing in a tuft together, which being ripe and turned into downe, are blowne away with the winde as others are.

3. *Hieracium Chondrillæ folio glabrum.*
Deepe jagged Hawkeweede.

This Hawkeweede differeth not much from the laſt, but that the leaves hereof are ſmooth, very much, and very deepely gaſhed even to the middle ribbe, each jagge being ſmall, narrow, and pointed; the ſtalkes and flowers, &c. are like thereunto.

4. *Hieracium minus præmorſa radice.*
Small Hawkeweede with bitten rootes.

The leaves of this Hawkeweede are many that lie nēxt the ground ſomewhat long and narrow cut in on the edges, into ſmall and ſhort pointed gaſhes: the ſtalkes are ſmall and grow to be ſcarce a foote high, parted into a few branches with ſome leaves here and there upon them that have no diviſion on the ſide: at the toppes whereof ſtand the flowers much ſeparate in ſunder each upo n a long ſtalke, and doe conſiſt of fewer leaves or leſſe double, of a gold yellow colour which turne into downe, &c. the roote is made of many ſtringes like a Plantane roote, but the middlemoſt that is greateſt, is ſhort, as if it had bēene bitten off like the Devills bit: the whole plant, and every part thereof, is very bitter rather more than any other.

The Place.

All theſe but the firſt grow plentifully enough in our Land in many placēs, and that about *Mompelier.*

The Time.

They flower with the reſt, that is in *Iune* and *Iuly.*

The Names.

The firſt is callēd by *Bauhinus*, who onely doth make mention of it, *Hieracium maximum æſperum Chondrillæ folio*: the ſecond is called by *Lobel Hieracium folijs & facie Chondrillæ*: the third *Bauhinus* calleth as it is in the title, and ſaith it is *Tabermontanus* his fift *Hieracium* which he called *Aphaca*: the laſt is the *Hieracium minus* of *Matthiolus*, *Tragus*, *Fuchſius*, *Geſner*, *Tabermontanus* and others; *Lobel* calleth it *Hieracium minus præmorſa radice*, and is *Tragus* his *Succiſa tertia*; and *Lactuca leporina*: *Lugdunenſis* calleth it *Picris Dalechampij*, becauſe of the bitterneſſe, and *Bauhinus Hieracium Chondrillæ folio ſucciſæ radice*, whereof he maketh a *majus* and a *minus*, yet ſaith hee himſelfe, that they may well be accounted but as one, differing onely in the greatneſſe and ſmoothneſſe of the leaves, and therefore I include them both in one.

The Vertues.

Theſe Hawkeweedes are no doubt as effectuall as the greater ſorts in every degree, and therefore whatſoever hath beene ſaid of them, may ſafely be applied to theſe, and therefore to avoid a tautologie, I referre you to them.

2. *Hieracium folijs & facie Choudrillæ Lobelij.*
Lobel his Gumme Succory-like Hawkeweede.

4. *Hieracium minus præmorsa radice.*
Small Hawkeweede with bitten rootes.

CHAP. XXXII.

Hieracia intubaceis folijs.
Garden Succory-like Hawkeweedes.

Quartus Ordo. The fourth Ranke.

1. *Hieracium intubaceum flore luteo.*
Yellow garden Succory-like Hawkeweede.

THis kinde of Succory Hawkeweede riſeth up with a ſlender ſmooth ſtalke about a foote high, yet ſomewhat leaning downewards, ſpread into many branches, at the foote whereof grow ſmooth long darke greene leaves, about foure inches in length, and one and a halfe in breadth, ſome of them without diviſions, and others eſpecially, thoſe that grow upwards very much, each of the ſtalkes and branches, being about an hand breadth bare unto the toppes, where eachof them carrieth a yellow flower of a middle ſize which turne into downe, and is carried away at the will of thewinde.

2. *Hieracium intubaceum flore magno albido medio luteo.*
White garden Succory-like Hawke-weeke.

This other Hawkeweeke is very like unto the former, but that the leaves are ſomewhat larger and broader, and more cut in or jagged on the ſides: the flowers alſo are whitiſh and more yellow in the middle, and ſomewhat reddiſh underneath.

3. *Hieracium intubaceum flore carneo.*
Bluſh garden Succory-like Hawkeweede.

The bluſh Hawkeweede hath divers long and ſomewhat narrow rough leaves lying next the ground, very much torne in on the edges, from among which riſe five or ſixe, or more ſlender ſhort browne and hairy ſtalkes, about a foote high or more, ſpreading a branch or two, with leſſer,

3. *Hieracium Intubaceum flore carneo.*
Bluſh garden Succory-like Hawkeweede.

and

and leſſe divided leaves thereon up to the toppes, where there are ſeverall large flowers, conſiſting of two or three rowes of leaves, of a deepe bluſh colour, of ſomewhat a ſtrong Opium-like ſent, broade pointed and nicked at the ends, the outermoſt row being larger than the inner, ſtanding in rough ſcaly huskes, wherein afterwards the ſlender long browne ſeede is contained, which lying among much downe, are carried away together with the winde: the roote is compoſed of a downeright ſtring, with other fibres thereat, which periſheth after ſeede time.

The Place

All theſe Hawkeweedes have come to us from *Italy*, where it is likely they are naturall.

The Time.

They flower from the middle of Summer to the end of *Auguſt*, and the ſeede ripeneth in the meane time.

The Names.

The firſt is called by *Bauhinus Hieracium Intubaceum flore luteo*, which he quoteth in his *Pinax* to be the eight in his *Prodromus*, miſtaken for the tenth; and the ſecond *Hieracium Intubaceum flore magno albido*, this is there alſo miſtaken for the eleventh: they have both come from *Italy*, and *Boel* likewiſe from *Liſhbone*, by the name of *Hieracium Aphacoides*, and *Sonchus Hierachitides*: the laſt is called by all Writers of it *Hieracium Intubaceum*, and *flore carneo*, and *ramoſum* by *Pona* in his *Italian Mount Baldus*, for he accounteth the *Hieracium parvum Creticum* of *Cluſius*, to be *Hieracium Intubaceum non ramoſum*, as I ſhewed you in the Chapter next ſave one before this: it is alſo aſſuredly the *Hieracium Apulum flore ſuaverubente* of *Columna*.

The Vertues.

Theſe kindes of Hawkeweeds are of the like temperature with the former, and may performe as much in their operation as they, and therefore I will referre you unto them to be informed of their qualities which may ſafely be transferred to theſe.

CHAP. XXXIII.

Hieracia Cichoriacea. Wilde Succory-like Hawkeweedes.

Quintus Ordo. The fift Ranke.

1. *Hieracio folio Hedypnoidis.* Yellow Succory-like Hawkeweede.

THis Hawkeweede hath a few leaves next the ground, ſomewhat long and narrow, wavēd or unevenly dented about the edges, in ſome more, in other leſſe, and ſometimes hairie withall, yet planted in Gardens hath little or none at all: it ſendeth forth a great many ſlender ſtalkes, with a few leaves ſet diſperſedly upon them, ſmaller than thoſe below, and branching at the toppes whereat ſtand ſeverall greene ſcaly huskes with yellow flowers in them, hanging downe their heads before they are blowen, wherein grow crooked ſeede lying in the downe, and are ſcattered where it pleaſeth the winde: the roote is long and white, with ſome ſmall fibres faſtened thereto.

2. *Hieracium falcatum ſive ſtellatum.* Starre-likē Hawkēweede.

The lower leaves of this Hawkeweede are ſomewhat long and narrow, with but three or foure dents on the ſides ending in a point: the ſtalkes are branched from the middle upwards, and at every joint a leafe under it bearing at the joynts and toppes ſeverall pale yellow ſmall flowers, which turne into heads of divers crooked ſeede like ſmall round and hard hornes or hookes, ſet all moſt round and ſtarre faſhion, ſome of the ſeedes being longer by halfe than others: the roote is milkie ſmall and ſtringy periſhing every yeare after ſeede time.

3. *Hieracium falcatum barbatum.* Herbe Impious-like Hawkeweede.

This impious Hawkweede (not that it hath any hurtfull qualitie therin, but becauſe the ſide branches riſe higher than the middlemoſt, like the herbe *Impia* or *Impious* Cottenweede) hath the lower leaves of two or three inches long, and one and a halfe broad, of a darke greene colour, and with but few dents on the edges: the ſtalkes are ſmall not a foote high, bearing but few leaves on them, and at the tops one ſmall flower, of a pale yellow colour, ſomewhat browner in the middle, compaſſed about with divers rough hornes which grow hairy or bearded and

1. *Hieracium facie Hedypnoidis.* Yellow Succory-like Hawkeweede.

sharpe pointed when they are ripe, from the bottome of this head riseth one and sometimes two small branches, about foure inches long with very narrow greene leaves set on them, and a flower at the toppe made after the same manner, and having sometimes a small branch or two rising from the head thereof in like manner as the other.

4. *Hieracium minimum sive marinum falcatum.*
The little sea Hawkeweede.

This little Hawkeweede riseth not a above halfe a foote high, and from a small long reddish roote, sendeth forth verie small thread like stalkes spreading into branches, bearing very small pale yellow flowers, which are compassed about with such like crooked hornes, sharpe pointed as are in the last: the leaves at the bottome are as small and narrow as they, but a little more dented about the edges.

The Place.

The first and second grow naturally both at *Mompelier* in *France* and in *Italy* also: the third at *Naples*, and in the wood *Gramuntium* which is hard by *Mompelier*: the last by the sea shore not farre from *Mompelier*.

The Time.

They keepe the same time that the rest doe.

The Names.

The first is called by *Cæsalpinus Rhagadiolus*, and by *Clusius Hieracium folio Hedypnoidis*: the second is called by *Lobel* and *Lugdunensis Hieracium Narbonense falcata siliqua*, by *Cæsalpinus Rhagadiolus alter*, by *Tabermontanus Hieracium Monspeliacum*, and *Narbonense*, of some *Italians Sonchus stellatus*, by others *Chondrilla stellata Hieracium falcatum* and *Hieracium Calthæ semine*: the third is called by *Columna Hieracium calyce barbato*, & by *Bauhinus Hieracium proliferum falcatum*, who thinketh it may be the *Hieracium minimum altreum* of *Clusius*: the fourth is remembred onely by *Bauhinus* by the name of *Hieracium minimum falcatum*.

The Vertues.

The Vertues of these Hawkweedes are alike unto the former sorts, and therefore there needeth not the same things to be spoken againe here which are there set downe

2. *Hieracium falcatum sive stellatum.*
Starrelike Hawkeweede.

CHAP. XXXIV.

Hieracia Montana glabra.
Smooth Mountaine Hawkeweedes.

Sextus Ordo. The sixt Ranke.

1. *Hieracium Montanum latifolium glabrum majus.*
Great smooth Mountaine Hawkeweede.

THis mountaine Hawkeweede hath divers faire great leaves, somewhat narrow at the lower ends, and broader to the middle where it is broadest, and ending in a point unevenly dented or waved about the edges, and compassing the stalkes as they rise up, which branching themselves beare three or foure flowers, as it were in an umbell together, which seldome appeare open, but when they doe they are yellow like unto others passing into downe, and then into the winde as others doe.

2. *Hieracium Montanum latifolium glabrum minus.*
Small smooth Mountaine Hawkeweede.

This other Mountaine Hawkeweede hath his leaves and flowers in all things like the last but smaller, and the whole plant lower and lesser, in other things it doth not differre.

3. *Hieracium Alpinum pumilum Chondrillæ folio.*
Small Mountaine Hawkeweede with Gumme Succory leaves.

This small Hawkeweede hath a few leaves next the ground about foure inches long of a pale greene colour, and scarcely dented or divided on the edges at all, every

1. *Hieracium latifolium montanum glabrum majus.*
Great smooth mountaine Hawkeweede.

one

one upon a long footeſtalke: but thoſe that grow up higher are of an inch long a peece upon the ſtalke which is not above an handbreadth high, and divided at the toppes into two or three ſmall branches, bearing every one a reaſonable large yellow flower like the others, and are more divided on the edges like unto the leaves of Garden Succory: the roote is ſmall, blackiſh without, white within, and abiding after ſeedetime.

4. *Hieracium Alpinum anguſtifolium.* The narroweſt mountaine Hawkeweede.

From the roote of this Hawkeweede which is reddiſh and ſomewhat wooddy ſpring forth divers very long and narrow graſſe like leaves being about an handbreadth long, ſmooth and of a darke greene colour, among which riſeth up a ſmooth round ſtraked ſtalke about a foote high or more bearing a few ſmall and ſhorter leaves thereon, and divided from the middle upward into ſundry branches having on each of them a ſmall yellow flower which paſſe into downe and then into the winde.

5. *Hieratium Tragopogonis folio.* Goates-beard Hawkeweede.

This mountaine Hawkeweede hath for his roote divers white ſtrings iſſuing from a ſmall blackiſh roote, and from it ſendeth forth divers long and narrow leaves like unto thoſe of Goates-beard, each of them of a fingers length guttured or halfe hollow all the length, of a grayiſh greene colour giving a bitter milke as others do, from among which riſeth a ſmall tender ſtalke not a foote high, with ſome few leaves ſparſedly ſet thereon ſmaller then the others, divided into ſome branches bearing ſmall yellow flowers like the others, out of ſcaly greene huskes paſſing into downe, that when it is ripe is with the ſmall ſeede carried away with the winde.

The Place.

All theſe ſorts of Hawkeweedes grow upon the Alpes, mount *Baldus* and others in *Germany* from whence they have beene brought to furniſh the gardens of the curious.

The Time.

They keepe the ſame time of flowring and ſeeding that the reſt doe.

The Names.

The firſt is the *Hieracium montanum majus latifolium* of *Tabermontanus*, whoſe true figure *Gerard* hath ſet forth under the name of *Chondrilla Hiſpanica*, but the deſcription pertaining thereunto is not anſwerable: the ſecond both *Tabermontanus* and *Gerard* from him ſet forth by the name of *Hieracium montanum latifolium minus*: the third *Bauhinus* hath ſet forth in his *Pinax* and *Prodromus* (but hath miſtaken the numbers in his *Pinax* in ſetting downe the ſeventh for the ninth in his *Prodromus* and ſo almoſt in all the reſt of the numbers following) by the name of *Hieracium Alpinum pumilum Chondrillæ folio*: the fourth is not numbred by *Bauhinus* in his *Pinax* but in his *Prodromus* by the name of *Hieracium Alpinum anguſtiſſimo oblongoque folio*, which I therefore here quote that the reader be not miſtaken therein: the fift or laſt *Cluſius* in his *Pannonicke* obſervations formerly ſet forth under the title of *Scorſonera quarta*, but better conſidering that the roote anſwered not to a *Scorſonera* altered the title in his hiſtory and maketh it his ſeventh *Hieracium humile*.

The Vertues.

You may likewiſe referre the vertues of the former to theſe ſorts of Hawkeweeds for they are thought to bee no leſſe effectuall then they in all the qualities and properties pertaining to them, for of any other particular qualitie in any of them I have not yet heard or read.

CHAP. XXXV.

Hieracia montana hirſuta. Hairy mountaine Hawkeweede.

Septimus ordo. The ſeventh ranke.

1. *Hieracium montanum Rapifolium.* Turnep leafed Hawkeweede

THis Hawkeweede ſendeth forth a few leaves ſtanding upon long and rough reddiſh footſtalkes next the ground ſomewhat like unto Turnep leaves being rough and torne in very much on the ſides into round pointed jagges, among whom riſeth up a rough reddiſh ſtraked ſtalke more then a cubit high, with one or two ſmall ſhort leaves thereon, divided toward the toppe into many ſmall branches, on every one whereof ſtandeth one flower for the moſt part, or ſometimes two, of a meane bigneſſe and yellow which turne into downe as the reſt: the roote is ſomewhat long and ſtringy of a reddiſh yellow colour.

2. *Hieracium montanum folijs dentatis flore magno.* Dented Hawkeweede.

The leaves of this Hawkweede lye for the moſt part all on the ground, being foure or five inches long, and one broad, a little woolly, and finely dented about the edges, of a ſad greene colour: the ſtalke that riſeth up to be a foote high is in a manner bare of leaves, rough and hollow, bearing one reaſonable large, deepe yellow flower at the top, ſtanding in a fine ſcaly huske which turneth into downe as the reſt.

3 *Hieracium ramoſum magno flore.* Great flowred Hawkeweede.

This large Hawkeweede hath a round rough ſtalke two cubits high parted into many branches, on every one whereof ſtandeth a large gold yellow flower like unto Dandelion; the leaves are an handbreadth long and three inches broad with a great ribbe in the middle, and many veines running through it, of a pale greene colour, and ſomewhat rough, waved about the edges, and ſet thereabout with ſmall haires, and many veines running from it.

4. *Hieracium Alpinum non laciniatum flore fuſco.*
Mountaine Hawkeweede with darke red flowers.

This mountaine Hawkeweede riſeth up with an hairy ſtalke two foote high bare of leaves from the middle upwards, and with a few hairy darke greene leaves at the bottome an hand breadth long, and three inches broad, pointed at the ends, and with a little freeſe about the edges: the flowers are of a red colour ſet many together which being ripe are turned into downe, and with the ſeede are blowne away: this is very like the *Piloſella major* ſet forth in my former booke, but is not the ſame.

5. *Hieracium pumilum Alpinum præmorsa radice.*
Dwarfe mountaine Hawkeweede.

8. *Hieracium montanum hirsutum minus.*
Small hairy Hawkeweede.

9. *Hieracium Alpinum latifolium villosum magno flore.*
Broad leafed mountaine Hawkeweede with a large flower.

10. *Hieracium montanum Dentis leonis folio incano.*
Mountaine hoary Dandelion like Hawkeweede.

5. *Hieracium pumilum Alpinum præmorsa radice.* Dwarfe mountaine Hawkeweede.

This dwarfe mountaine Hawkeweede hath a ſhort blackiſh roote, bitten as it were halfe off with ſome other ſtrings ſet thereat likewiſe, ſending forth ſundry hairy long leaves about three or foure inches long and halfe an inch broad, with long footeſtalkes under them, cut in on the edges in three or foure places on each ſide, among which riſe up divers hairy ſlender ſtalkes, not above an handbreadth high without any leafe thereon except it be one or two at the moſt bearing one flower a peece, of a pale yellow colour.

There is ſome varietie obſerved in this ſort, one bearing ſhorter and rounder leaves without any footeſtalkes under them: another that hath the ſtalke branched forth diverſly. *Altera*

6. *Hieracium montanum lanuginoſum laciniatum parvo flore.* Mountaine woolly Hawkeweede.

This mountaine woolly Hawkeweede hath from a long darke red roote many thicke woolly long leaves of a darke greene colour, as it were ſpotted, and deepely torne in on the edges about three inches long, and one and a halfe broad, yet ſome narrower, each of them upon a footeſtalke, among which riſeth up a ſmall ſoft ſtalke of an handbreadth high, bearing a few ſmall yellow flowers at the toppes.

7. *Hieracium Alpinum pumilum lanuginoſum.* Small mountaine woolly Hawkeweede.

This is ſmaller then the laſt and hath more hairy or woolly leaves of a fingers length and halfe the breadth: the ſtalke is about foure inches long, bearing a yellow flower like unto the reſt, the roote is thicke and hath blackiſh ſtrings.

8. *Hieracium montanum hirſutum minus.* Small hairy Hawkeweede.

This ſmall Hawkeweede hath a few ſmall leaves about an inch long and ſomewhat hairy, cut in or waved on the edges, the ſtalke is without branch or leafe, or ſeldome any appearing (and ſomet me by the aboundance of nouriſhment it receiveth growing bigger in the middle) bearing a ſmall pale yellow flower like unto a Sowthiſtle and with ſuch a greene huske under it.

9. *Hieracium Alpinum latifolium villoſum magno flore.*
Broad leafed mountaine Hawkeweede with a large flower.

This broad leafed Hawkeweede hath the lower leaves long and ſomewhat narrow covered with a long hairy downe almoſt hoary, but thoſe that grow up higher upon the hairy ſtalke which is about a foote high are ſomewhat ſhorter but three times broader then they, pointed at the ends and leſſe hairy: the ſtalke is branched into two or three parts, every one bearing one flower uſually, yet ſometimes two or three out of woolly huskes of the forme and colour of other Hawkeweedes.

10. *Hieracium montanum Dentis leonis folio incano.* Mountaine hoary Dandelion like Hawkeweede.

The rootes of this Hawkeweede lye longwiſe under ground with divers fibres ſhooting downewards, and ſending divers heads of leaves upwards, which are not all of an equall length, but ſome longer and ſhorter then others as of one two or more inches long, and halfe an inch broad, with a great or thicke middle ribbe, covered over with a ſoft hairy downe or cotten, the lower part of them being narrower & much torne in on the ſides, and the upper part broader and but onely dented: from among which riſe two or three ſtalkes of a foote long, with-

12. *Hieracium montanum anguſtifolium.*
Cluſius his narrow leafed mountaine Hawkeweede.

13. *Hieracium latifolium Pannonicum.*
Broad leafed Hawkeweede of *Hungary*.

out

out any leaves, and bearing one large flower at the toppe, of a deeper yellow colour then in many others.

11. *Hieracium Britanicum Cluſii Conyzæfolio.* Fleabane like Hawkeweede.

This Hawkeweede riſeth up with round ſtraked reddiſh greene ſtalkes halfe a yard high, ſet with ſomewhat large rough leaves like unto thoſe of Fleabane without order, but not ſo fat or thicke and dented about the edges, compaſſing them at the bottome, and pointed at the ends: the flowers are yellow like other Hawkeweedes, ſet in hairy huskes upon long footeſtalkes which turne into downe, and with the whitiſh long ſeede is blowne away with the winde: the roote is compoſed of many blackiſh ſtrings which periſh not but abide many yeares.

12. *Hieracium montanum anguſtifolium ſive ſextum Cluſii.*

Cluſius his narrow leafed mountaine Hawkeweede.

The narrow leafed mountaine Hawkeweede of *Cluſius*, yeeldeth from the long and thicke blackiſh roote, divers heads of long and narrow ſharpe pointed leaves ſomewhat hoary upon the greene, from among the leaves of every head ſtart up naked hard ſtalkes about halfe a foote long, bearing one large yellow flower at the toppe like unto others, and flying away in downe in the ſame manner.

Alterum. This kind is found to vary ſometimes, having the leaves a little waved about the edges, and ſometimes leſſe hoary, and of a darke greene colour.

13. *Hieracium latifolium Pannonicum ſive primum Cluſii.*

Broad leafed Hawkeweede of *Hungary*.

This Hawkeweede of *Hungary* hath divers large hoary leaves lying next the ground ſometimes a little waved other whiles torne on the edges, ſometimes with blacke ſpots on them and ſometimes without any, among which riſeth up an hairy ſtalke with very few leaves thereon, parted at the toppe into two or three other branches, with every of them a large yellow flower like the great Hawkeweedes.

Vnto this ranke or order is alſo to be referred the *Bugloſſum luteum vulgare* of *Camerarius* and *Gerard*, which is our *Laugdebeefe* called by *Lobel Bugloſſum Echioides luteum Hieracio cognatum*, and by *Tabermontanus Hieracium Echioides luteum*, and by *Bauhinus Hieracium Echioides capitulis Cardui Benedicti*, but that I have expreſſed it in my former booke.

The Place.

All theſe ſorts of Hawkeweedes are growing upon hills and mountaines in ſeverall places of *Italy* and *Germany*, *&c.* and are alſo found many of them in divers places of our owne Land.

The Time.

They doe all flower in the Summer when the other ſorts doe.

The Names.

The firſt three ſorts and the ſixt *Bauhinus* onely hath made mention of by the ſeverall names are in their titles: the fourth *Columna* calleth *Hieracium Germanicum fratris Gregorii*, and the fift *Hieracium pumilum quintum ejuſdem (ſc. fratris) Bauhinus* maketh them the 17. and 19. in his *Prodromus* by the titles here expreſſed; the ſixt is his twentieth; the ſeaventh is likewiſe called by *Columna Hieracium pumilum ſecundum*, and the eighth *Hieracium montanum aſperum*: the ninth is called by *Cluſius Hieracium quintum villoſum*, and by *Tabermontanus Hieracium latifolium montanum*: the tenth is the eighth *Hieracium folio Hedypnoides* of *Cluſius*, which *Tabermontanus* calleth *Hieracium montanum anguſtifolium foliis Cichoraceis*: the eleventh is called by *Cluſius Hieracium Britanicum*, and is his fourth kind: the twelfth is as is ſaid in the title; the ſixt ſort of *Cluſius* called by *Tabermontanus Hieracium montanum anguſtifolium ſecundum*: the laſt is the firſt *Hieracium latifolium* of *Cluſius* called by *Camerarius Hieracium latifolium Pannonicum*, and as he ſaith by ſome *Italians Coſta*, or *Herba Coſta*, and by others *Ingraſſia di porci*, and by *Tabermontanus Hieracium Phlomoides*.

The Vertues.

There is no doubt but that theſe ſort of Hawkeweedes are as effectuall as any of the former, both their formē and bitter taſte expreſſing their qualities, yet the laſt hath beene found by many in our Land to have a particular propertie, but ſet downe by no other Author then *Camerarius*, who ſaith concerning it, that it is ſingular good for the Tiſſicke or conſumuption of the Lungs, to be taken either made into a Syrupe or Conſerve, or the powther of the dryed herbe taken with hony, or as he ſaith they doe in *Myſia*, put it into their Sallets, broths and meates for the ſame purpoſe, and is availeable for the pluriſie alſo without any helpe of blood letting as it is affirmed by many credible perſons.

CHAP. XXXVI.

Hieracia pratenſia. Medow Hawkeweedes.

Octavus ordo. The eight ranke.

1. *Hieracium profunde ſinuatum pubeſcens.* Medow Hawkeweede with deepe cut leaves.

THis Hawkeweede hath divers long and narrow leaves next the ground deepely cut in or torne on the edges, and pointed at the ends with long footeſtalkes under them, and covered with a ſoft downy hairineſſe as all the plant elſe is: the ſtalke is hollow, round and three foote high, having a few ſuch like deepe cut leaves thereon and branched diverſly, whereon ſtand gold yellow flowers on ſeverall long footeſtalkes which paſſe into downe like the reſt: the roote is blackiſh and wooddy.

2. *Hieracium pratenſe non ſinuatum majus.* The greater uncut medow Hawkeweede.

The many and divers rough leaves that lye about the roote of this Hawkeweede upon the ground are of five inches long a peece, and one and a halfe broad, without any gaſh or dent on the edges being very greene, and ending in a round point, from among which riſeth up one ſingle ſtraight and creſted ſtalke about a cubit high, wholly naked or deſtitute of leaves, bearing at the toppe a number of ſmall yellow flowers, ſet cloſe together as it were in a tuft every one upon a ſhort footeſtalke, which doe as the reſt turne into downe and then into the wind: the roote is ſmall and blacke with divers long ſtrings faſtned thereto.

3. *Hiera-*

3. *Hieracium pratenſe non ſinuatum minus.* The leſſer uncut Medow Hawkeweede.

This other and leſſer Hawkeweede hath many leſſer leaves & uncut next the ground, of an inch and a halfe long, and one broade, being almoſt round and rough: the ſtalke that riſeth from the middle of them ſtandeth upright, and is creſted, bearing at the toppe a few ſuch like flowers as the former turning into downe: the roote is ſomewhat long and of a meane ſiſe.

The Place.

Theſe doe grow in the fields and medowes, and by woodes ſides that lie open to the Sunne.

The Time.

They flower and ſeede when the former doe.

The Names.

Bauhinus giveth the name of the firſt, as it is in the title: the ſecond and third *Thalius* maketh his ninth and tenth *Intubus*, calling them *Intubus ἀφυλλόκαυλος major* and *minor*, and *Bauhinus Hieracium pratenſe non ſimiatum majus* and *minus*.

The Vertues.

Theſe being Hawkeweedes as their face and outward forme ſheweth them to be, the vertues of the Hawkoweedes may be in ſome ſort appropriated unto them.

CHAP. XXXVII.

Hieracia fruticoſa. Buſhie Hawkeweedes.

Novus Ordo. The ninth Ranke.

1. *Hieracium fruticoſum latifolium glabrum.* Buſhie Hawkeweede with ſmooth broad leaves.

THis firſt buſhie Hawkeweede ſendeth forth from a blackiſh fibrous roote ſome round ſtraight hairie ſtalkes three foote high, ſet here and there without any order, with ſoft hairie or woolly leaves dented, or as it were bearded about the edges, foure or five inches long, and one and a halfe broad, of a darke greene colour and pointed at the ends: the toppes of the ſtalkes runne into ſhort ſprayes bearing every one a ſmall pale yellow flower.

4. *Hieracium fruticoſum anguſtifolium majus.* The great buſhie Hawkeweede with narrow leaves.

Heiracium murorum Bauhini quod eſt Pulmonaria Gallorum Lobelij. *Bauhinus* his more hairy Hawkeweede of the walls, which is *Lobels French Pulmonaria.*

2. *Hieracium*

2. *Hieracium fruticosum folio subrotundo.* Round leafed bushie Hawkeweede.

The stalke hereof is about a cubit long, straked, round, and somewhat rough, divided at the toppes into sundry branches, three or foure inches long a peece, every one upholding a pale yellow flower, the leaves that compasse the stalke at the lower end are somewhat round, about an inch and a halfe broad, yet ending in a little point dented about the edges, and of a light greene colour somewhat hoarie.

3. *Hieracium fruticosum latifolium hirsutum.* Bushie Hawkeweede with rough broade leaves.

This broad leafed Hawkeweede hath divers broad and somewhat long hard rough darke greene leaves, lying on the ground without any incismes or dents on the edges; the stalke that riseth up among them is two or three foote high, thicke set with such leaves but lesse unto the toppe, where stand a few yellow flowers consisting of fewer leaves than in others, being but of one row of leaves bordering a middle thrumme which turneth into downe: the roote is wholly composed of strings and small fibres, which yeeldeth milke as most of the Hawkeweedes doe: sometimes this is found to varie with lesse rough, or rather with soft leaves, and sometimes with broader and shorter.

Varietas.

4. *Hieracium fruticosum angustifolium majus.*

The greater Bushie Hawkeweede with narrow leaves.

This other bushie Hawkeweede groweth very like the last, but hath longer and narrower leaves, somewhat rough and dented or waved about the edges: the stalke is more branched at the toppe where the flowers are more and thicker, of faire yellow leaves, the roote is whitish very long and deepely spreading into the ground possessing a great deale of ground quickly, for every little peece will grow being broken, and not easie to be rid out againe.

5. *Hieracium fruticosum minus.*

The lesser bushie Hawkeweede.

This lesser buskie Hawkeweede riseth up with a single single stalke halfe a yeard high, set about with diver shorts and smooth leaves in some places, and with almost round rough leaves in others, dented about the edges, bearing divers yellow flowers upon short footestalkes, at the toppe like unto the last: the roote is short, and as it were bitten off without any fibres at it.

6. *Hieracium Murorum angustifolium.*

Narrow leafed Hawkeweede of the walles.

6. Hieracium murorum angustifolium.
Narrow leafed Hawkeweede of the walls.

From a thicke reddish roote riseth up a round rough stalke almost two foote high, set with a few short and narrow leaves dispersed thereon, at the toppe whereof stand many small yellow flowers as it were in a tuft or umbell close set together, every one on a small long foote stalke: the leaves that grow at the foote hereof, and next to the ground, are many long and narrow of sixe inches long, and scarce halfe an inch broad, covered with a soft downe or freese, which grow shorter as they rise higher on the stalke: this is found much smaller about *Padoa* as *Bauhinus* saith.

The Place.

Although these are set downe by *Bauhinus* and others to grow in severall places in *Germany*, *&c.* yet some of them have beene found in our owne Land, as I have oftentimes gathethered in the way to *Hampstead-Heath*, and backe againe, especially the third and the fourth.

The Time.

These keepe the same time of flowring and seeding or rather later.

The Names.

The first is called by *Bauhinus* as it is in the title, & is the second *Hieracium latifolium* of *Clusius*: the second is so called also by *Bauhinus*, as I have here downe: the third is taken to be the *Erinus Matthioli*, yet no way answering to his figure as *Lobel* saith, being much bigger than it, and as it is thought by divers that the figure is but a figment, for it is not certainly knowne what herbe among all we have should be the right *Erinus* of *Dioscorides*, in that none doth answer it in all points: *Lobel* in his *Adversaria*, would referre both the *Esula dulcis Tragi* hereunto, and his *Esula sylvestris* also, because they give milke, and their leaves doe neareſt resemble *Basill* whereunto *Dioscorides* compareth the leaves of *Erinus*, and therefore as it should seeme *Castor Durantes* calleth *Erinus Mattholi Basilicum aquaticum*: *Guilandinus* calleth this *Hieracium Militaris Galeni*, and *Lactaris Plinij*, who being demanded what herbe *Matthiolus* his *Erinus* should be, shewed this *Hieracium*, *Hortus Eystetensis*, calleth it *Hieracium fruticosum latifolium polyanthos*, & called also by some *Hieracium Sabaudum latifolium*, as the fourth is called by *Lobel Hieracium Sabaudum angustifolium*, and *Hieracium alterum grandius*, for he maketh them to be both one, although the description of their leaves be much differing, it is the third *Hieracium* of *Clusius*, for as he saith himself it hath great affinitie unto *Lobels*, if it be not the same, *Dodonæus* maketh it his first *Hieracium*, *Gerard* maketh it his *Hieracium Intubacium*, and *Bauhinus* calleth it *Hieracium fruticosum angustifolium majus*, as he doth the fift *Hieracium fruticosum minus*: the last is added to this ranke not having any other of that sort to ranke with it, (for *Bauhinus* his other sorts of *Hieracium murorum*, the one is our *Pilosella major*, called *Auricula muris major Tragi*, of some *Chondrilla aurea* and *Palmonaria Gallorum*, or *Gallica* which *Lugdunensis* very unfitly calleth *Corchorus Dalechampij*, but is not *Costa Camerarij*, as *Bauhinus* seemeth to suppose, for *Camerarius* referreth it to the *Hieracium latifolium Pannonicum* of *Clusius*, as I said before in the last Chapter save one, and his other is the *Palmonaria Gallica fœmina* of *Tabermontanus* if they be severall (being noted to be *Laciniatum*) and not one and is called by *Bauhinus Hieracium murorum angustifolium non sinuatum*. I have given you that figure here of *Lobel* which hath narrower leaves to be compared with this of *Bauhinus*.

The

The Vertues.

There is none of these Hawkeweedes inferiour to any of the former in their qualities as farre as may be judged by their taste for we have no further experience set downe by any, and therefore if yee will so take them yee neede not a repetition of the same things againe that have beene delivered, but I will referre you to the first ranke of Hawkeweedes, to peruse the vertues there appropriated to them and transferre them if you please hereunto. And so much shall serve to have spoken of the whole family of the Hawkeweedes.

CHAP. XXXVIII.

Sonchus. Sow-thistle.

DIoscorides and the other ancient writers have set downe but two sorts of Sow-thistles, dividing them into rough or prickly and smooth, *Pliny* into blacke and white, *Theophrastus* mentioneth onely the rough kind: but since their time there have beene sundry other herbes found out, which doe so nearely resemble them, that they are therefore referred unto them as shall bee presently shewed: but because there are so many that beare that title I thinke good to avoid confusion to distribute them into sundry Chapters as you shall finde them mentioned.

Sonchi asperes. Prickly Sow-thistles.

Ordo primus. The first ranke.

1. *Sonchus asper major non laciniatus.* The greater prickly Sow-thistle with whole leaves.

This prickly Sow-thistle hath somewhat long and broad leaves of a whitish greene colour, unevenly dented, but not gashed or torne on the edges, and every dent set with a sharpe and short pricke somewhat hard, and sometimes prickly also along the middle ribbe on the under side, yeelding a more bitter milke in every part where it is broken then the smoother kind: the stalke is somewhat tender, and as it were winged with a filme running upon it, rough and sharpe, set with such like leaves as grow below, diversly branched with small pale yellow flowers at the toppes which turne into downe and are blowne away: the roote is long yellowish and somewhat hard when it is growen up with a stalke with a number of small fibres set thereat.

2. *Sonchus asper minor non laciniatus.* The lesser prickly Sow-thistle with whole leaves.

The lesser Sow-thistle is in all things like the other but lesser in every part, having a rounder stalke seldome above a foote high, somewhat firmer and not so tender, with smaller leaves but as sharpe and prickly as the former, some because this doth more usually grow in the fertile grounds, doe account it to be the cause that the leaves are whole and not rent, which is but an opinion with small reason therefore.

1. *Sonchus asper major non laciniatus.*
The greater prickly Sow-thistle with whole leaves.

4 *Sonchus asper laciniatus Creticus.*
Prickly Sow-thistle of *Candy*.

3. *Sonchus*

3. *Sonchus asper laciniatus.* Common prickly Sow-thistle.

This common Sow-thistle hath the leaves very much cut or torne on the edges into three or foure parts much separate asunder one from another, and smaller peeces of leaves set betweene them of a whitish greene colour like the former, and having prickles on the dented edges likewise: the stalke groweth very high sometimes, rough and prickly, with such leaves thereon as are below, branched at the toppe, where grow such like pale yellow flowers turning into downe: the roote is like the other.

4. *Sonchus asper laciniatus Creticus.* Prickly Sow-thistle of *Candy*.

This *Candy* Sow-thistle hath the first leaves little or nothing divided on the edges of an handbreadth long and more, but those that rise up with the stalke are very much torne on the edges into great and deepe gashes, set with some prickes likewise; the stalke is rough, straked and hollow, halfe a yard high, branched from the middle upwards, with such like leaves but smaller set at the joynts, at the toppes whereof stand large yellow flowers in rough greene huskes upon long footestalkes which turne into downe as the other.

5. *Sonchus asper subrotundo folio major.*

The greater round leafed prickly Sow-thistle.

The greater of these two round leafed prickly Sow-thistles riseth up with a round hollow stalke not a foote high, set with many short prickles at the bottome, whereabout grow a few leaves that are somewhat round and an inch and a halfe long, some whereof are waved about the edges, and all of them a little prickly as well on the edges as on the backes, the stalke is branched at the toppe into two or three parts, every one with a small pale yellow flower like unto an Hawkeweede, which afterwards is turned into downe and into the winde: the roote is small and long with fibres set thereat.

6. *Sonchus asper subrotundo folio minor.*

The lesser round leafed prickly Sow-thistle.

This is a smaller sort by many degrees having small threadlike rootes and two small stalkes about foure or six inches long, bearing onely one small yellow flower at the toppe, the leaves that lie on the ground being six or seven in number are small and round pointed, and dented about the edges.

7. *Sonchus fruticosus petræus Africanus spinosus.*
Thorny shrub Sow-thistle of *Africa*.

This kinde of Sow-thistle groweth somewhat high, with wooddy stalkes and branches much spread at the toppe, and every twigge ending in very sharpe prickes or thornes, the lower leaves are much jagged and prickly, the upper smaller and little or nothing jagged, the flowers are small, single, and pale yellow, whose seede succeeding is with the downe as the rest carried away with the winde.

The Place.

These Sow-thistles grow in unmanured as well as in manured soyles, some in Orchards and Gardens where the leaves are usually lesser and lesser divided then in the rough and unmanured grounds: the last as the title declareth among the rockes and stony grounds about *Tunis* and *Sapphi*, found by *Boel* and brought to us.

The Time.

They doe all flower and shed their seede from Midsommer or thereabout all the Sommer long, and sometime untill *August* be past, but the last hardly endureth a Winter with us.

The Names.

It is called in Greeke Σόγχος ἀπὸ τῦ σῶον χέειν, *quod salubrem fundat succum*: the Latines also call it *Sonchus*, and this kind is called *Asper*, *asperior* or *sylvestris* to put a difference betweene it and the next which is *lævis* or *lævior*. The first is called by *Tragus Intubus sylvestris seu erraticus acutis foliis*, and by *Cordus* in *historia Sonchus asper major*, by *Lobel Sonchus tenerior aculeis asperior aut horridiuscula*, by *Dodonæus* and *Lugdunensis Sonchus asperior*, by *Cæsalpinus Sonchus alter in ruderibus*, and by *Bauhinus Sonchus asper non laciniatus*: the second is called by *Cordus* in *historia*, *Sonchus asper minor*: the third is the *Sonchus asper* of *Matthiolus*, *Fuchsius*, *Gesner* and others, by *Ericius Cordus Cicerbita asperior*, by *Anguilara Sonchus spinosus* and by *Lugdunensis Andryala major*: the fourth *Bauhinus* onely mentioneth by the name of *Sonchus asper laciniatus Creticus* as it is in the title: the fift and the sixt hee likewise so calleth, *Sonchus asper subrotundo folio major & minor*: the last hath his name in his title as it is fittest for it.

The Vertues.

The properties of these rougher or more prickly Sow-thistles are alike with the next, which are the smoother, and therefore because they are more generally used I shall give you the vertues of these under them, and comprehend them both in one to bee the more succinct, and to avoid a tautologie, or needelesse repetion of one thing twise.

CHAP.

CHAP. XXXIX.

Sonchi læves vulgaris. Smooth Sow-thistles.

Ordo secundus. The second ranke.

1. *Sonchus lævis.* Common Sow-thistle.

THis common Sow-thistle is well knowne to rise up with a round hollow stalke three or foure foote high or more sometimes, if it grow in good grounds and in gardens as usually it doth, set with many long and much torne leaves of a whitish greene colour, not having that roughnesse or those sharpe prickles on them as are in the former kind, branching forth towards the toppe into divers branches bearing pale yellow flowers which passe away into downe & with the seed into the wind, the roote groweth downe right, and hath many fibres thereat perishing likewise every yeare, and raising it selfe of its owne sowing, and is as plentifull in giving milke as the former, which is somewhat pleasanter and not so bitter.

2. *Sonchus lævis alter parvis floribus.* The lesser smooth Sow-thistle.

This lesser Sow-thistle groweth not so high nor hath so many leaves set on the stalke, but are long and more torne on the edges, else not unlike to the former, the many branches of the stalke have fewer and smaller leaves on them, and the flowers are much smaller, yet of the same pale yellow colour in most, which passe away into downe as the rest, &c.

3. *Sonchus lævis latifolius flore albo.* Broad leafed Sow-thistle with white flowers.

The leaves of this are like the last but somewhat larger and broader and with fewer divisions on the edges: the flowers hereof are white, which with the forme of the leaves make the difference.

4. *Sonchus lævis angustifolius.* Narrow leafed Sow-thistle.

This Sow-thistle hath but few and those very long and narrow leaves whose lower parts are narrowest and have no incisure at all, but from the middle almost forwards they are broader and have divers gashes on both sides, some greater and deeper and others smaller especially towards the ends where they are broadest: the stalkes grow somewhat low and divided but into one or two branches, set sparingly with leaves, the uppermost whereof are long but not divided or very little compassing the stalke, at the foote bearing one large yellowish flower upon a long straked toppe branch, which being ripe flyeth away: the roote giveth milke as the whole plant else beside, and is long and slender with a few fibres.

5. *Sonchus lævis valde laciniatus.* Sow-thistle with fine cut leaves.

The leaves of this Sow-thistle that grow lowest are long and divided into many slender jaggēs, but those that

1. *Sonchus lævis vulgaris.*
Common Sow-thistle.

2. *Sonchus lævis alter parvis floribus.*
The lesser smooth Sow-thistle.

3. *Sonchus lævis latifolius flore albo.*
Broad leafed Sow-thistle with white flowers.

4. *Sonchus lævis augustifolius.*
Narrow leafed Sow-thistle.

are set at the joynts of the slender smooth greene and high stalke where it brancheth, are somewhat greater and not so finely cut in on the edges, at the toppes are yellowish flowers like the others, of a middle sise which grow into downe.

6. *Sonchus angustifolius maritimus.* Sea narrow leafed Sow-thistle.

This Sea Sow-thistle from a slender long roote wanting fibres rise many long darke greene leaves, some of foure and some of six inches long and scarse one inch broad, a little rough, with small prickles about the edges which give milke as the others doe, and among them one slender stalke about a foote or lesse high, with two or three leaves thereon which compasse it at the bottome, and beare one or seldome two yellow flowers at the top, of a reasonable bignesse, which passe away into downe, &c.

The Place.

The first, and second sometimes also, grow in Gardens and manured grounds, and sometimes by old walls the pathsides of fields, highwayes, but the third and the fourth in *Germany*: the fift about *Mompelier* and *Florence* also, where they eate it familiarly as the common: the last is found in the Iland of *Lio* in the Venetian teritory, and by *Mompelier* also.

The Time.

They doe flower quickly after they are sprung, for it is late before they rise out of the ground, and abide untill *August*.

The Names.

It is called *Sonchus lævis* in Latine to distinguish the one from the other as is sayd before: some call it *Cicerbita* as the *Italians* doe to this day. *Apuleius* calleth it *Lactuca leporina*, and the *Germans* thereafter, *Hasen Lattauwe*, some also *Hasen Koll*, that is, *Brassica leporina*: it may well be accounted as a kind of wilde Lettice it is so like it, others therefore call it *Lactucella* and *Lacterones* from the *French Laicterons*, *Tragus* calleth the first *Intybus sylvestris sive erratica tertia*, *Lonicerus Endivia sylvestris*, *Lugdunensis Andryala minor Dalechampij*, *Cordus in historia Sonchus lenis seu lævis*, all other authors *Sonchus lævis*, or *non aspera*, or *vulgaris*, or *laciniatis foliis*: the second *Matthiolus* calleth *Sonchus lævis alter*, and *Lobel Sonchus alter profundis lacinijs sinuato hederaceo*, *Clusius Sonchus lævis vulgaris secundus*, *Tabermontanus Sonchus sylvaticus quartus*; *Anguilara* calleth it *Scariola sylvestris Lactucæ species Galeni*, *Gesner in hortis Germaniæ Lactuca sylvestris flore luteo*, which although it doth in the outward face resemble somewhat, yet it is much more bitter, and never eaten as the other sorts of sallet herbes; and *Cæsalpinus Lactuca murorum*, *Bauhinus* calleth it *Sonchus lævis laciniatus muralis parvis floribus*: the third *Tabermontanus* and *Gerard* have set forth by the same name is in the title, and *Bauhinus Sonchus lævis minor paucioribus lacinijs*; the fourth *Lobel* setteth forth in his Dutch Herball by the name of *Sonchus lævis Matthioli*, *Gesner in Hortis* calleth it *Sonchi genus terra crispa*, and *Cæsalpinus* saith they call it *Terra crepola in Heotruria* or *Florence*, *Lugduuensis* setteth it forth for *Crepis Dalechampij*, and *Bauhinus* calleth it *Sonchus lævis angustifolius*: the fift and sixt are set forth onely by *Bauhinus* by the names of *Sonchus lævis in plurimas & tenuissimas lacinia divisus*

diviſus and *Sonchus anguſtifolius maritimus*: the *Italians* doe call it *Soncho liſcio*, and *Cicerbita gentile*; the *Spaniards Serraya* and *Sevalla*; the *French Lacterones*, and *Palais au lieure* from the *Latine Palatium leporis*, and as ſome have it *Leporum cubile*; the *Germans Gens diſtell*, *Sow-diſtel* and *Dudiſtell*; the *Dutch Ganſen diſteb* and *Melke weye*; and we in *Engliſh* generally Sow-thiſtle, and of ſome Hares-lettice.

The Vertues.

Theſe as well as the former Sow-thiſtles are cooling and ſomewhat binding, and are very fit to coole an hot ſtomacke, and to eaſe the gnawing paines thereof, they are uſually eaten as ſalet herbes in the Winter and Spring, while they are young and tender by thoſe beyond the ſeas familiarly, but the rootes are much more eſteemed by them being very tender and ſweete: the herbe boyled in wine is very helpefull to ſtay the diſſolutions of the ſtomacke, and the milke that is taken from the ſtalkes when they are broken given in drinke, is beneficiall to thoſe that are ſhort winded and have a wheeſing withall: *Eraſiſtratus*, ſaith *Pliny*, did therewith cauſe the gravell and ſtone to be voided by urine, and ſaith, that the eating thereof helpeth a ſtinking breath: the juyce thereof to the quantitie of three ſpoonfulls taken in white wine warmed, and ſome oyle put thereto, cauſeth women in travell of child to have ſo eaſie and ſpeedy delivery, that they may be able to walke preſently after: the ſaid juyce taken in warme drinke helpeth the ſtrangurie or piſſing by droppes, and paines in making water: the decoction of the leaves and ſtalkes given to Nourſes cavſeth abundance of milke, and their children to be well coloured, and is good for thoſe whoſe milke doe curdle in their breaſts: the juyce boyled or throughly heated with a little oyle of bitter Almonds in the pill of a Pomegranate and dropped into the eares, is a ſure remedy for deafeneſſe and ſingings and all other diſeaſes in the eares, it is ſaid that the herbe bruiſed and bound upon wartes will quickly take them away: the herbe bruiſed or the juyce is profitably applied to all hot inflammations in the eyes, or whereſoever elſe, and for puſtules, wheales, bliſters, or other the like eruptions of heate in the skinne, as alſo for the heate and itchings of the *hemorrhoides* or piles and the heate and ſharpeneſſe of humours hapning in the ſecret parts of man or woman; the diſtilled water of the herbe is not onely effectuall for all the diſeaſes aforeſaid, to be taken inwardly with a little Sugar, which medicine the daintieſt ſtomacke that is will not refuſe it, or outwardly by applying cloathes or ſpunges wetted therein: but is wonderfully good for women to waſh their faces to cleare the skinne and to give a luſtre thereunto.

CHAP. XL.

Sonchi Montani. Mountaine Sow-thiſtles.

Tertius Ordo. The third Ranke.

1. *Sonchus Alpinus cæruleus.* Blew flowred mountaine Sow-thiſtle.

THis mountaine Sow-thiſtle hath divers broad and long leaves much cut in to the midle ribbe, and dented alſo on the edges, the end peeces being the broadeſt, of a greene colour on the upper ſide, and grayiſh underneath, cõpaſſing the ſtalke at the bottome, which is round, rough, and ſet with hard reddiſh haires about three foote high branched at the toppe, with leſſer and leſſe divided leaves on them: the flowers ſtand many together in ſmall hairie greene tufts upon purpliſh hairie foote ſtalkes, everie one conſiſting of twentie and more ſmall narrow leaves, broad at the ends and nicked in of a purpliſh blew colour like unto Suecory, which turne into downe as other ſorts doe, & are blowne away; the maine roote is great, thicke, white and hard, very intricately foulded with long ſtrings faſtned ſtrongly in the earth, which periſheth not but abideth many yeares by the ſhew of the dry ſtalkes: this giveth milke in as plentifull manner as the others doe and is very bitter. There is another of this ſort, whoſe leaves are more divided into ſmaller parts, yet the end peece is longeſt like the other, and ſo are the flowers but more ſparſedly ſet at the toppes ſomewhat leſſer alſo, and of a fairer blew colour.

1. *Sonchus Alpinus cæruleus.*
Blew flowred Mountaine Sowt-thiſtle.

2. *Sonchus arboreſcens.* The greateſt Sow-thiſtle.

This Sow-thiſtle groweth to the height of any man, with a ſtrong ſtalke of the bigneſſe of a mans thumme, ſmooth ſtraked and without any pricke whereabout are ſet many leaves, parted into foure and ſometimes into five diviſions placed on each ſide one againſt another, and compaſſing it about at the lower end, where they have ſmall peeces ſticking forth beyond the ſtalke, the upper leaves have no diviſions nor prickles on the backes but on the edges upon the dents, and are greene on the upperſide, and grayiſh underneath and full of milke: the ſtalke is parted at the toppe into ſundry branches, bearing at the toppes many flowers ſet together, as it were in an umbell, all of them being ſet to an even height, ſmall in compariſon of the tallneſſe of the plant, elſe not much unlike thoſe of

1. *Sonchus Alpinus cæruleus alter.*
Another blew flhvvred Mountaine Sow-thistle.

2. *Sonchus arboreſcens.*
The greateſt Sow-thiſtle.

3. *Sonchus Dendroides Dalechampij.*
Tall Sow-thiſtle without branches.

4. *Sonchus montanus laciniatus minor.*
The leſſer Mountaine Sowthiſtle.

the common Sow-thiſtle, compoſed of many yellow leaves cut in at the ends, compaſſing a middle thrumme which is more yellow, which when they are ripe paſſe into downe with grayiſh ſtriped ſeede therein, both which are carried away with the winde: the roote is great and whitiſh ſet with many great fibres, and periſheth not, but yearely encreaſeth.

3. *Sonchus Dendroides Dalechampij.* Tall Sow-thiſtle without branches.

This other tall Sow-thiſtle which *Dalechampius* found, and *Lugdunenſis* hath ſet forth, hath a great blackiſh root with divers ſtrings faſtened thereto, from whence riſe divers ſtrong, tall, round ſtalkes, two cubits high or more without any branches at all, but thicke ſet with broad leaves from the bottome to the toppes on both ſides, waved or cut in on the edges, ſmaller at the bottomes and broader toward the ends which are pointed: from the toppes of the ſtalkes, and likewiſe from the joynts with the leaves come forth ſhort foote ſtalkes, with three or foure ſmall Lettice or Sow-thiſtle-like flowers on them, which turne into downe, and ſo into the winde as others doe.

4. *Sonchus Montanus laciniatus minor.* The leſſer Mountaine Sow-thiſtle

This leſſer Mountaine Sow-thiſtle hath the ſtalke next the ground for a ſmall ſpace ſmooth and round, ſomewhat thicke and wooddy, which then breaketh out into branches, and riſeth to the height of two foote or there abouts, ſet about with divers leaves farre in ſunder one from another of an inch and a halfe long, and cut in on the ſides into ſeverall peeces, and pointed at the ends, the flowers ſtand at the toppes of the ſtalkes and branches, many ſet one above another, as it were in a ſpike, being ſmall and yellowiſh, which being ripe is turned into downe, and carried away with the winde as all the reſt are; the roote is ſomewhat blacke

The Place.

All theſe (but the ſecond which groweth among Willowes and Reedes, and yet I have here inſerted for the tallneſſe thereof) grow upon the hills in *Auſtria* and other places, and for their raritie are nurſed up in Gardens.

The Time.

Theſe in their naturall places flower ſomewhat late, but tranſplanted are in flower about *July*, and their ſeede ripeneth as they flower.

The Names.

The firſt is called by *Camerarius* upon *Matthiolus Sonchus cæruleus* and *Sonchocichorum*, by *Thalius Sonchus πλατοφύλλος Harcynica*, the other of this ſorts is *Cluſius* his *Sonchus lævior Auſtriacus cæruleo flore*: the ſecond is the fifth *Sonchus* of *Cluſius*, which he calleth *Sonchus lævior Auſtriacus altiſſimus*; the third is, as I ſaid, called by *Lugdunenſis Sonchus Dendroides Dalechampij*: the fourth *Bauhinus* ſetteth forth by the name of *Sonchus montanus lævis laciniatus minor.*

The Vertues.

Theſe Sow-thiſtles are of the like qualitie and operation with the former, and therefore whatſoever hath beene ſaid of the other before may be transferred to theſe to ſave a repetition of the ſame things.

CHAP. XLI.

Sonchi hirſuti ſive villoſi.
Hairy or woolly Sow-thiſtles.

Ordo quartus. The fourth ranke.

1. *Sonchus villoſus luteus major.*
The greater woolly Sow-thiſtle.

THe greater woolly Sow-thiſtle hath divers very woolly long rough and ſomewhat narrow leaves lying on the ground pointed at the ends, and unevenly waved at large diſtances on the edges, with a white middle ribbe in them, from among which riſeth up a woolly cornered ſtalke a cubit high ſet with ſuch like woolly leaves thereon but leſſer and leſſer up to the toppe where it breaketh forth into ſome few branches, with ſoft woolly heads on them, out of which come gold yellow flowers, like in forme unto the ordinary Sow-thiſtle, and like it alſo, is blowne away being ripe: the whole plant yeeldeth milke as the Succories doe, and is almoſt as bitter: the roote is very long, white and ſlender, with divers ſmall fibres thereat.

2. *Sonchus villoſus luteus minor.*
The leſſer woolly Sow-thiſtle.

This leſſer ſort hath from a ſmall reddiſh long roote almoſt without fibres, two or three round woolly ſtalkes halfe a foote high, parted at the toppe into two or three branches, whereon grow very narrow leaves about an inch long, little or nothing divided on the edges, but thoſe that grow lower and at the ground are narrow and about foure inches long, with ſome rents or diviſions upon them ſet farre a ſunder one from another, the flowers are of a deepe gold yellow colour ſtanding in ſmall huskes, covered with a very ſoft and woolly downe which paſſe into downe, and are blowne away with the winde.

1. *Sonchus villoſus luteus major.*
The greater woolly Sow-thiſtle.

The place.

Both theſe plants are found in the woods about *Mompelier* in *France*, and in ſome other places of *Spaine* and *Italy*.

The Time.

They flower in the moneth of *Iune* and *Iuly*, and the ſeede ripeneth quickly after, even with the other flowers.

The Names.

The firſt is called by *Lugdunenſis Sonchus lanatus* becauſe of the whiteneſſe, like unto wooll, and ſome as hee ſaith did call it alſo *Mollugo* from the ſoft woollineſſe thereof, but yet is not the *Mollugo Plinij*. *Bauhinus* calleth it *Sonchus villoſus luteus major* or as he doth the other *Sonchus villoſus luteus minor*, and is called alſo by ſome *Hieracium tomentoſum*, and therefore might be referred to that family, but that I follow my author herein:

The Vertues.

Theſe alſo are ſomewhat bitter more like Hawkeweede then Sow-thiſtles, and therefore may be applyed accordingly, for there is no author hath written any thing more particularly hereof.

CHAP. XLII.

Lampſana. Nipplewort.

I Was almoſt indifferent whether I ſhould ſet this plant next after the Hawkeweedes and before the Sow-thiſtles or after, in regard it commeth ſo neare unto both of them: but let it take place here now, as partaking more with thoſe than theſe in my opinion, yet whereas all former writers have made but one ſort thereof, *Bauhinus* hath added thereunto another that commeth very neare it, as you ſhall heare by and by; and I am bold to adde a third, which in my opinion may well be accounted as one of them.

1. *Lampſana vulgaris.* The ordinary Nipplewort.

This herbe *Lampſana* (which I have entituled Nipplewort for the reaſons hereafter declared) ſendeth forth ſundry hard upright ſtalkes, whereon grow darke greene leaves from the bottome to the toppes, but leſſer ſtill the higher, in ſome places whole without any dents on the edges, and in others with a few uneven cuts therein ſomewhat like a kinde of Hawkeweede: the toppes of the ſtalkes have ſome ſmall long branches which beare many ſmall ſtarrelike yellowiſh flowers on them which turne into ſmall ſeede: the roote is ſmall and threddy, this yeeldeth a bitter milke as the others doe.

2. *Lampſana Auſtriaca.* Nipplewort of *Auſtria.*

This other herbe (which I hold may be accounted as one of this kinde) hath ſlender ſmooth and ſolid ſtalkes not eaſie to breake, a cubit high or more, whereon are ſet without order ſomewhat long and narrow leaves broadeſt in the middle and ſharpe at the ends, waved a little about the edges and compaſſing them at the bottome, yeelding a little milke: from the upper joynts with the leaves grow forth ſmall firme branches, yet a little bending bea-

1. *Lampſana vulgaris.*
The ordinary Nipplewort.

2. *Lampſana Auſtriaca.*
Nipplewort of *Auſtria.*

ring

ring each of them foure or five long greene huskes and in them ſmall purpliſh flowers of five leaves a peece nicked in at the broad ends, with ſome ſmall threds in the middle, which turne into downe and ſo into the winde: the roote is ſmall and fibrous laſting many yeares.

3. *Soncho affinis Lampſana ſylvatica.* Wilde or wood baſtard Nipplewort.

This wilde or wood kinde is like into the firſt ſort, but with ſomewhat broader leaves, and more ſtore of branches, elſe in flowers and other parts not ſo much differing.

The Place.

The firſt groweth upon the bankes of ditches and the borders of fields almoſt every where: the other *Cluſius* ſaith hee found in *Hungarie* and in *Saxonies Harcynia ſylva* and other places: the laſt is found neare woods ſides and hedges rowes.

The Time.

They flower in the Sommer, and their ſeede ripeneth ſoone after.

The Names.

The firſt is taken by many to be the λαμψάνη of *Dioſcorides* ἀπὸ τοῦ λάπτω *quod lambere ſignificat, quia foliorum mollitie caduca decubituve in humum eam lambere videatur*, and thereupon ſome call it *Lapſana*: but I ſee no reaſon of this difinition: the Latines keepe the ſame name of *Lampſana* or as ſome have it *Lapſana*, but I make ſome doubt thereof, for although *Dioſcorides* giveth no deſcription thereof as being well enough knowne in his time yet hee maketh it to be a ſallet or potherbe whereon the poorer ſort of people did feede, as being the meaneſt and cheapeſt of all others (which out of *Pliny lib.* 19. *c.* 8. may alſo be gathered, when as *Iulius Cæſars* Souldiers at *Dirrhachium* complained of the parcimony of their allowance in diet for their ſervice by feeding on *Lampſana*, and ſang verſes thereof in ſport: the ſame *Pliny* alſo ſaith it was of the old *Romans* called *Napium quaſi Napum ſylveſtre*, which was the cauſe of *Matthiolus*, *Anguilara*, *Geſner*, *Lobel* and *Lugdunenſis*, their opinion that tooke for it a kinde of *Rapiſtrum* or *Charlocke* with pods, as all their figures expreſſe it, and as ſhall be ſhewed more amply in the proper place where I ſhall entreate of their kinde) but this herbe hath no probabilitie to be the right, being never received by any that we can heare of to be as foode to feede upon: *Gerard* hath foulely faulted in a double manner firſt in ſetting forth a falſe figure to that *Lampſana*, which he uſually ſhewed to all that went in company with him abroad in Simpling, which even this that is here ſet forth and generally with all Herbariſts in theſe times called *Lampſana* which differeth much from a Charlock that hath long pods: and then in giving it the name of *Dock Creſſes* as though it were ſome wilde kind of *Creſſes*, when as more truly as *Lobel* in *Adverſarijs* ſaith it may be referred to an *Hieracium* or as I ſay to a *Sonchus*. The firſt is called *Lampſana* by *Lobel* and *Dodonæus* in his laſt Edition (for in his former he tooke it to bee *Eryſimum*) and *Lugdunenſis* who all give one and the ſame true figure of this herbe as alſo by *Thalius* and *Camerarius* who ſaith that in *Pruſſia* they call it *Papillaria*, becauſe it is good to heale the Vlcers of the Nipples of womens breaſts, and thereupon I have entituled it Nipplewort in *Engliſh*: by *Geſner in hortis* it is called *Sonchis cognatum* and *in bello de collectione ſtirpium Cichorium vel Sonchi genus*. *Gerard* his Figure of *Sonchus ſylvaticus* doth more truly repreſent this *Lampſana* then his Figure he giveth for it. The ſecond is called by *Cluſius Sonchus lævior Pannonicus quartus purpureo flore*, but I have entituled it *Lampſana Auſtriaca*, ſuppoſing it may more fitly agree thereunto, then unto a wilde Lettice as *Bauhinus* doth, who calleth it *Lactuca montana purpureo flore*: *Columna* as I ſayd before ſaith that this of *Cluſius* was like his *Sonchus montanus purpureus* but differed in ſome things and ſo doe I alſo, as firſt in the roote, *Columna* his not being ſo ſtringie as this of *Cluſius*, and the flowers hereof having five leaves and his but foure, and therefore I take them to be divers plants: If I have erred herein I referre me to his cenſure that can confute mee by proofe: the laſt is *Tabermontanus Sonchus ſylvaticus ſecundus*, which *Bauhinus* calleth *Soncho affinis Lampſana ſylvatica*.

The Vertues.

We have no properties to ſhew you of this *Lampſana*, more then what *Camerarius* as I ſayd before hath given us to underſtand, which is that they in *Pruſſia* from the vertues to heale womens breaſts, and their nipples when they are ſore or exulcerated call it *Papillaris* which may induce us to thinke that it hath an eſpeciall healing qualitie therein, and that it is temperate in heate and drineſſe, with ſome tenuitie of parts able to digeſt the virulency of thoſe ſharpe humors that breake out into thoſe parts.

CHAP. XLIII.

Lactuca Sativa. Manured or Garden Lettice.

THere are two kinds of Lettice, the one of the Garden, the other wilde. Of the Garden kinds I have in my former booke given you the knowledge of ſo many ſorts, that it might ſeeme there had beene no more to have beene ſet forth, for I there ſhewed you eleven ſeverall ſorts beſides that ſmall Sallet herbe called Lambes Lettice or Corne Sallet, which although it be no kind of Lettice as all know well enough, yet performeth the office of Lettice in a Sallet, whoſe Figure I here give you, and the ordinary Garden kinde alſo, but upon further ſearch I have two other ſorts to bring to your conſideration which ſhall bee declared in this Chapter, and the wilde kinds in the next to cloſe up this Claſſis.

1. *Lactuca folio oblongo acuto.* Sharpe pointed Garden Lettice.

This Lettice differeth not in ſtalkes, or flowers, or manner of growing from other ſorts of open Lettice that doe not cabbage, but in the leaves onely, which are about foure inches long and two inches broad, dented about the edges and ending in a ſmall point, the middle ribbe being great that runneth through the leafe.

2. *Lactuca Italica laciniatis foliis.* *Italian* jagged Lettice.

This *Italian* Lettice alſo differeth not from the ordinary ſort but in the leaves which are cut into many ſmall parts, of a pale greene colour, very tender and pleaſant to eate.

The Place.

Theſe ſorts come from *Italy* and are there nourſed up in the Gardens of the curious, but ſcarſe knowne to us as yet.

The

Lactuca ſativa.
Garden Lettice.

The Time.

Their time of flowring, ſeeding, and ſpending is thē ſame with the common ſort.

The Names.

Lettice is called θρίδαξ *Thridax* in Greeke, and in Latinē *Lactuca a lactis copia.* The firſt is taken by *Bauhinus* to bee the *Lactuca Gallica* of *Caſtor Durantes*, and calleth it himſelfe *Lactuca folio oblongo acuto*, the other alſo is called by him *Lactuca Italica laciniata*, and we in *Engliſh* thereafter *Italian* jagged Lettice, the *Arabians* call Lettice *Chas* and *Cherbas*, the *Italians Lattuga*, the *Spaniards Lechuga* and *Alfalſa*, the *French Laittue*, the *Germans Lattik*, the *Dutch Lattouwe*, and we in *Engliſh* Lettice.

The Vertues.

Although theſe ſorts of Lettice doe differ in forme from the other, & each of them alſo one from another in the forme oftheir leaves, yet in qualitie they are alike, and acceptable to an hot ſtomacke troubled with choller, yeelding good nouriſhment to the body, as both *Serapio* and *Galen* teſtifie of the experience thereof on themſelves, and *Pliny* alſo ſheweth that the learned Phyſition *Muſa* did by Lettice eaſe *Auguſtus* of the violence of his diſeaſe. *Galen* ſheweth that the eating of boyled Lettice at night when hee went to bed procured him reſt and ſleepe, who ſhould have had none if hee had beene without it, having uſed himſelfe to watching from his yonger dayes: the ſame is found effectuall alſo with divers, or the juice thereof mixed or boyled with oyle of Roſes and applied to the forehead and temples, both to procure reſt and ſleepe and to eaſe the headach of any hot cauſe: being eaten raw or boyled it helpeth to looſen the belly, and the boyled more then the raw, which eaten laſt performeth it the better and was generally ſo uſed in ancient dayes which made the Poet *Martiall* move this queſtion ſeeing the contrary courſe held in his time.

1. *Lactuca oblongo folio acuto.*
Sharpe pointed Garden Lettice.

Lactuca agnina.
Lambes Lettice or Corne Sallet.

Clandere

Claudere quæ cœnas Lactuca ſolebat avorum,
Dic mihi cur noſtras inchoat illa dapes. Which may be thus,

Lettice that earſt our Grandſires meales did cloſe,
Why it begins, pray tell me whence it growes.

It helpeth digeſtion, quẽcheth thirſt, helpeth to encrẽaſe milke in Nourſes, and eaſeth all griping paines of the ſtomacke or bowels that come of Choller: it abateth bodily luſt, and therefore both it and Rue are commended for Monkes, Nunnes and the like ſort of people to eate, and uſe to keepe them the chaſter: it repreſſeth alſo venerous dreames, and applyed outwardly to the Cods with a little Camfire, abateth the pride and heate of luſt which ſome call the Coltes evill; applyed alſo in the ſame manner to the region of the Heart, Liver, or Reynes, or by bathing the ſaid place with the juice or diſtilled water, wherein ſome white Saunders and red Roſes are put alſo, is not onely a repercuſſive medicine to ſtay and repreſſe the heate and inflammations therein, but doth alſo comfort and ſtrengthen thoſe parts: the ſame alſo tempereth the heate of Vrine, *Galen* adviſeth old men to uſe it with ſpices to conſerve the radicall moyſture, and that where ſpices are wanting to adde Mintes, Rocket, and ſuch like hot Sallet herbes, or elſe Citron, Lemon, or Orrenge ſeedes, or the young ſhootes of them, to abate the cold of the one and the heate of the other. The ſeede and the diſtilled water of the Lettice worke the like effects in all things: but the uſe of the Lettice is chiefly forbidden thoſe that are ſhort winded or have any imperfection in their Lungs or doe uſe to ſpit blood; *Galen* ſaith it did hurt his teeth and ſome ſay it hurteth the ſight.

CHAP. XLIIII.

Lactuca ſylveſtris. Wilde Lettice.

OF the wilde Lettice there are two or three ſorts to bee declared in this Chapter, wherewith I ſhall cloſe and finiſh this Claſſis of cooling herbes.

1. *Lactuca ſylveſtris Endiviæ folijs odore viroſo.* Broad leafed wilde Lettice.

This wilde Lettice riſeth up with foure or five ſomewhat long and large leaves, ſmaller at the bottome and broader at the ends being round pointed, unevenly dented about the edges but not cut in or torne at all, of a pale or whitiſh greene colour, and very like unto the Garden Lettice, or Garden Endive leaves, ſo that it will ſoone deceive one that never ſaw it before, which doe ſoe abide the firſt winter after the ſowing, whether in the Spring or Autumne of the ſhed ſeede: but in *May* following it beginneth to riſe up to a ſtalke, and then thoſe lower leaves will have the middle ribbe on the backe ſide ſet full of ſmall ſharpe prickes: the ſtalke hath riſen in my Garden to be eight foote high at the leaſt, and as bigge as the thumbe of any mans hand at the lower joynt, ſomewhat browne and ſpreading into divers very long branches, whereon are ſet large leaves like the other but more crumpled, the lower and ſo to the middle of the ſtalke ſet with prickes in the manner of the bottome leaves, but leſſer, and higher, ſomewhat more jagged or divided on the edges, all and every part yeelding plenty of milke being broken, which ſmelleth ſtrong, very like unto Opium or bitter in taſte: the flowers are very ſmall and ſingle ſomewhat like unto Lettice, but ſmaller and paler yellow, ſcarſe opening themſelves, and ſcarſe abiding alſo halfe a day open, but turne into downe with ſmall blacke ſeede therewith very like unto blacke Lettice ſeede, and is carryed away with the winde: the roote is white long and wooddy when it beareth ſeede and periſheth preſently after.

2. *Lactuca ſylveſtris laciniata.* Wilde Lettice with jagged leaves.

This other wilde Lettice groweth like the laſt but not ſo high or great, the firſt leaves are of a grayer greene colour, ſmaller and narrower then the other, which ſo abide and afterwards gaine thornes or prickes on their backſides as the other hath: thoſe that follow are much more jagged then the others, and ſet with ſharpe prickes alſo, yelding milke as plentifull being broken and as bitter as the former, but doth ſmell as ſtrongly of Poppie or Opium as the other: the flowers and ſeede are like it flying away with the winde, but the roote hereof abideth after ſeede when as the other doth not.

1. *Lactuca ſylveſtris Endiviæ folijs odore viroſo.* Broad leafed wilde Lettice.

3. *Lactuca ſylveſtris purpureo flore.* Wilde Lettice with purple flowers.

This great plant ſometimes in moyſt grounds riſeth up to be foure or five cubits high but uſually two or three with a ſtrong great ſtalke ſet on each ſide with leaves ſmalleſt at the bottome, and larger as they riſe up higher, being largeſt about the middle of the ſtalke, and then grow ſmaller againe up to the toppe, all of them unevenly waved about the edges, and compaſſing it at the bottome, of a darke blewiſh greene colour on the upper ſide and grayiſh underneath yeelding a milke when it is broken: the flowers ſtand upon ſmall long ſtalkes iſſuing from the joynts with the leaves from the middle upwards, with many flowers on them, conſiſting of foure darke purple coloured leaves with divers threds in the middle, tipt with a yellow duſt & a three forked ſtile in the midſt, which ſtandeth in long purpliſh greene huskes hanging downe their heads and turne into

Downe

2. *Lactuca sylvestris laciniata.*
Wilde Lettice with jagged leaves.

3. *Lactuca sylvestris purpureo flore.*
Wild Lettice with purple flowers.

Downe with ſmooth grayiſh ſeede among it flying away with the winde: the root is thicke and ſet with nodes in divers places not growing downewards, but ſpreading forwards, and having long fibres ſhooting from it which periſh not.

The Place.

The two firſt grow in divers places of our owne Land as well as beyond Sea, the firſt in the borders of fields and by the hedges and lanes ſides of *Buckinghamſhire*, the other on a high banke by the footeway going downe *Grayes-Inne-lane* unto *Bradford* bridge and in many other places, the laſt is found upon hills and mountaines in divers parts of *Germany* mentioned both by *Geſner*, *Thalius* and others, and in *Naples* alſo as *Columna* ſaith.

The Time.

They doe all flower about *Iuly*, and their ſeede ripeneth and is blowne away while it is in flower and hath young buds on it.

The Names.

It is called in Greeke Θριδακινη *Thridacine*, and θριδαξ ἀγελα by *Dioſcorides* derived as it is thought παρὰ τὰ θεῖα *quæ uti folio ficulneo lactis non expertia ſunt*, ſome ſaith *Pliny*, *lib.* 19. *cap.* 8. called it *Endochion*, in Latine *Lactuca agreſtis* and *ſylveſtris a lactis copia*, becauſe it giveth more ſtore of milke then any of the Endives or Succory doe, or becauſe it cauſeth milke in women. There is a controverſie among our moderne writers what plant ſhould be the true *Lactuca ſylveſtris* of *Dioſcorides*, *Theophraſtus* and *Galen*, ſome allowing of one that others diſprove, for that which *Matthiolus* ſetteth forth, *Lobel* findeth fault withall, calling it *Seris domeſtica*. The firſt is called by *Tragus Endivia major*, as hee calleth the other *Endivia vulgaris*, yet hee calleth the ſame plants in another place of his booke *Lactuca ſylveſtris prior* and *altera*, his later ſort being the firſt here, and his *Prima* the other. *Bauhinus* in my minde hath erred in miſſetting *Tragus* his *Endivia major*, both making it a Garden Lettice, calling it *Lactuca Endiviæ folio*, and a *Lactuca ſylveſtris* alſo, but how can it be both a Garden and a wilde Lettice, the one not having any bitterneſſe therein nor prickles on the leaves, and the other having both. *Lobel* calleth it *Lactuca ſylveſtris Scariolæ hortenſis folio lactucæ flore Opij odore*, *Lugdunenſis* ſetteth it downe in the Chapter of Lettice for *Lactuca ſylveſtris vera Dalechampij*, and in the 14. Chapter of the ſame Booke calleth this firſt *Theſion Dalechampij*, whereof *Pliny* out of *Theophraſtus* maketh mention. *Camerarius* calleth it *Lactuca ſylveſtris Anglica odore Opij*. The ſecond is called *Lactuca ſylveſtris* by *Matthiolus*, *Fuchſius Dodonæus*, *Cæſalpinus*, *Thalius* and others, *Brunfelſius* and *Tragus* as I ſayd call it *Endivia vulgaris*, becauſe generally in all *Germane* Apothecaries ſhops it was ſo accounted and uſed, taken from the *Italians*, whoſe Phiſitions not knowing any other permitted the errour, *Lobel* calleth it *Seris domeſtica altera lactucina Dioſcoridis*, and *Ericius Cordus Scarriola* and *Serriola* according to the received opinion thereof in their time to be Endive. The laſt is called by *Geſner in Hortis Lactuca ſylveſtris flore purpureo*, and *Sonchus arboreſcens puniceo flore*, *Thalius Lactuca ſylveſtris* ἐξυδενδρος

and

and *Columna*, *Sonchus montanus purpureus πτεροφόρος*, *Tabermontanus* maketh it his third *Sonchus*, and taketh it to be the *Libanotis sterilis* of *Theophrastus* which *Gerard* setteth forth under the title of *Eryſimum ſylveſtre*, and *Bauhinus* calleth it *Lactuca montana purpuro cærulea major*, becauſe he maketh that to be the *minor* hereof which I call *Lampſana Auſtriaca*. The *Italians* call this wild kind *Lattuga ſalvatica*, the *Spaniards Lechuga ſalvaja* and *Alfalſa ſalvaja*, the *French Laittue ſauuage*, the *Germans Wilder Lettick*, the *Dutch* wilde *Lattouwe*, and wee in *Engliſh* Wilde Lettice.

The Vertues.

The wilde Lettice is neare the ſame propertie of cooling that the Garden kinde is, although the bitterneſſe therein maketh it the more opening, but not heating even as it is in Succory, Poppie, Opium & the like, whoſe bitterneſſe doth rather open a way for the qualities to worke the better, no cold qualitie being powerfull of it ſelfe, and therefore as Succory, Poppie, or Opium it is more availeable to procure ſleepe then the Garden kinde, and to eaſe them that are given to much watching, which by the ſeede, the juice or the diſtilled water drunke or outwardly applyed performeth well, the milke of the wilde Lettice gathered and dryed in the Sunne and given in Vinegar diſtilled is ſayd to purge the water of the Dropſie, to provoke womens courſes, and to helpe the ſting or poyſon of the Scorpion and Spider *Phalangium*: the diſtilled water of the whole herbe is ſingular good to quench the thirſt in any burning or peſtilentiall fever: the ſaid juice diſſolved in white wine and a little hony mixed therewith being dropped into the eyes doth wonderfully ſtrengthen the ſight, and cleareth them from miſtes, clouds filmes or skins growing over them. And as ſome are of opinion that it may bē uſed in ſtead of the Garden kinde for any the phyſicall purpoſes before mentioned.

PLAN-

PLANTÆ CALLIDÆ ET ACRES.
HOT AND SHARPE BITING PLANTS.
CLASSIS SEPTIMA, *THE SEVENTH TRIBE.*

CHAP. I.

Eruca. Rocket.

FRom the cooling herbes I am now come to those that are hot, sharpe, and biting upon the tongue, especially such as are not umbelliferous or more properly belong to another Classis.

There are divers sorts of Rocket, some growing in gardens, whereof I have set forth one in my former booke, which is the most common with us, and called by *Camerarius in horto Eruca tertia Anglica*, as I take it: some wilde growing in divers differing places, others that grow neare the sea side: to speake of them severally in divers Chapters is the best way, and not to cloy one Chapter with too many sorts.

1. *Eruca sativa alba.* White or *Romane* garden Rocket with white seede.

The *Romane* Rocket is a smaller plant than our garden kinde, having somewhat broad leaves cut in on the edges, but not so much nor so deepe, each part being rounder, and round at the end, nothing so hot also or sharpe in taste: the stalke hath some leaves thereon, lesser, and lesse jagged, and beareth white flowers at the toppes, made of foure somewhat long and round pointed leaves, after which come short pods somewhat long and round with a small peece at the end, wherein is contained whitish round seede: the roote is small & perisheth presently after the seede is ripe. We have an other very like in leaves unto the former, whose stalke riseth three or foure foote high, branched into many parts with the like leaves on them, and large whitish flowers at the toppes of foure leaves apeece, also round pointed, with a blackish line in the middle, of each leafe having slender long pods with small blackish browne seede therein: the roote perishing in like manner.

Altera semine nigrescente.

2. *Eruca latifolia.* Great Garden Rocket.

This large Rocket hath broader and larger divisions at the leaves, and smaller at the ends than our ordinarie garden Rocket, and each part more unevenly dented about the edges, the flowers hereof are more yellow and enclining to a gold colour, and the seedē smaller and darker in smaller and longer pods.

3. *Eruca maxima Americana.* Great Rocket of *America*.

This fruitfull herbe riseth up to a mans height, with a number of rough hairy stalkes branching forth on all sides, and set with divers long and pointed leaves unevenly dented about the edges, somewhat like unto those of *Lysimachia* Loose strife, but having a small downy hairinesse upon them tasting somewhat sweete at the first but sharpe afterwards, the flowers are many that stand at the ends of the stalkes and branches, consisting of foure yellow leaves apeece, which turne into slender long pods, containing small seede that are sweetish, and therefore I have rather placed it here for the mildnesse than with the wilde sorts.

The Place.

Both these former kindes of Rockets are nursed up in gardens in all places and countries, their naturall place being not well knowne, yet it is thought that the first is originally from the sea side in some country: the other of that sort came to us from *Boel* by the name of *Eruca Aragonica*: the last from that part of *America* which the *French* possesse called *Canada*.

The Time.

They doe flower about *Iune* and *Iuly*, and their seede is ripe in *August*.

The Names.

It is called in Greeke ἔρυζωμον *obsuavitatem in condiendis obsonijs*, and *Eruca* in *Latine*, *quod vellicando linguam quasi erodat*: the *Arabians* call it *Jergir* and *Ergir*: the *Italians Ruchetta* and *Rucola gentile*: the *Spaniards*: *Oruga*

and

Eruca ſativa alba. Garden Rocket with white ſeede.

3. *Eruca maxima Americana.* Great Rocket of *America.*

and *Aruga*: the *French Roquette*: the *Germans Rauken* and *Rockelen*: the *Dutch Rukette*: and we in *Engliſh* Garden Rocket, *Romane* Rocket, Rocket gentle, and white Muſtrad ſeede. The firſt is called by *Tragus Eruca ſive Rucula marina major*, by *Cordus in hiſtoria Erucula major*, yet he giveth thereunto long blacke ſeedes which cannot agree to this, and quoteth *Tragus* to agree with his, which hath yellowiſh ſeede; of *Lugdunenſis Sinapi hortenſe & album*; and *Lobel Sinapi ſativum ſemine albo duplo quam Thlaſpi vulgaris majore*: there is no other that I know hath expreſſed this ſort, for *Matthiolus* and others have ſet forth a garden kinde that beareth yellow flowers, and ſmall browne ſeede in ſlender long pods, which *Camerarius* calleth *Eruca Anglica*: we doe uſually call this *Eruca flore & ſemine albo*, to put a difference betweene it and the other: the ſecond is called by *Bauhinus Eruca latifolia*, and mentioned by no other: the laſt is ſet forth by *Cornutus* among his *Canada* plants.

The Vertues.

This Rocket gentle ſo called from the *Italians* who by that title of Gentle, underſtand any thing that maketh one quicke and ready to jeſt, to play, or to Venery as this herbe doth, or that it is more pleaſant and gentle in taſte, than the wilde kinde; it is ſeldome eaten alone but among Lettice, Purſlaine, or ſome other cold herbes to temper each others cold and heate: for as it is ſaid by *Galen* it procureth head-ach if it be taken alone: it is in a manner wholly ſpent as a ſawſe or condiment to meate, to quicken the appetite and to pleaſe the palate, or to encreaſe ſperme and Venerous effects, for which purpoſes *Martiall* ſheweth the effects in theſe Verſes.

Et Venerem revocans Eruca morantem.

And *Columella* thus, *Iamque Eruca ſalax fœcundo provenit horto.*

And *Ovid* *Nec minus Erucas jubeo vitare ſalaces.*

But as for any Phyſicall qualitie I know not any it is employed upon, for that the wilde Rockets, as you ſhall heare by and by, are uſed for all ſuch purpoſes, except in the want of the one the other may be taken, but as it is more milde and gentle in taſte, ſo it is alſo in operation.

CHAP. II.

Eruca ſylveſtris. Wilde Rocket.

OF the wilde Rockets that are more ſeldome uſed for ſallets or ſawſe except unto churliſh ſtomackes, and are moſt ſpent in Phyſicall uſes, there are divers ſorts, as ſhall be here declared in this Chapter, and the other three that follow.

1. *Eruca ſylveſtris vulgatior.* The more common wilde Rocket.

This common wilde Rocket hath longer and narrower leaves much more divided, and into ſlenderer cuts and jagges on both ſides of the middle ribbe, of a ſad over-worne greene colour, from among which ri-

seth up divers stiffe stalkes two or three foote high, sometimes set with the like leaves but smaller, and smaller upwards, branched from the middle into divers stiffe stalkes, bearing sundry yellow flowers on them made of foure leaves a peece as the others are, which afterwards yeeld small reddish seede in small long pods, of a more bitter and hot biting taste than the other, as the leaves are also.

2. *Eruca sylvestris minor parvo flore.*
Small ill smelling wilde Rocket.

This small wilde Rocket doth not much differ from the last but in the smellnesse of the leaves, branches, flowers, and pods, for in all it is lesser, and the leaves, although as much divided, yet into smaller parts, and smelleth nothing well.

3. *Eruca sylvestris minor Bursæ pastoris folio.*
Small wilde Rocket of *Mompelier*.

This is a very small Rocket, the stalke not growing much above an hand breadth high, and somewhat rough withall parted into small and short branches with a few leaves upon them at the joynts, which are little or nothing divided, but those that grow at the foote of the stalke next the ground, are somewhat long and more cut in on the edges into divers parts, much like the leaves of Shepherdes purse, and rough likewise; the flowers are somewhat large and yellow standing upon long foote stalkes, after which come small seede in small and short pods.

4. *Eruca sylvestris minor incana.*
Small hoary wilde Rocket.

The hoarie wilde Rocket riseth up with divers hoarie or whitish greene stalkes halfe a foote high, and sometimes lower, branching forth at the toppes into short sprigges of an inch long, bearing many small yellow flowers which turne into very slender and short pods with seede: the leaves at the bottome are many very small cut and jagged, and hoarie over the whitish greene, as those upon the stalkes growing on each side one above another are also.

1. *Eruca sylvestris vulgatior.*
The more common wilde Rocket.

5. *Eruca cærulea.* Blew flowred Rocket.

6. *Eruca sylvestris angustifolia.* Narrow leafed wilde Rocket.

5. *Eru*

5. *Eruca cærulea.* Blew flowred Rocket.

This kinde of Rocket hath the loweſt leaves cut in on both ſides ſomewhat like a Rocket, but more like Groundſell in my mind, from among which riſe up divers hairy ſtraked ſtalkes ſcarce a foote high, bearing rough hairy leaves on them, leſſe jagged, and ſome not at all, ſhorter alſo and narrower: at the toppes ſtand the flowers one above another of an excellent purpliſh blew colour made of foure leaves, after which come ſmall long ſmooth pods with ſmall reddiſh ſharpe ſeedes therein: the roote is long ſlender and reddiſh with ſome fibres thereat.

6. *Eruca ſylveſtris anguſtifolia.* Narrow leafed wilde Rocket.

This plant is doubtfull whereunto it might be referred, in that it participateth of divers plants, namely of the leaves of Tarragon long and narrow of the colour of Rocket; the yellow flowers of wilde Rocket upon ſtalkes a cubite high with cods of Muſtard or Creſſes and hot ſharpe ſeede, and the whole face of *Eryſimum* Bancke Creſſes, yet the taſte of Rocket.

The Place.

Many of theſe are found wilde in divers places of our Land, although they are recorded by divers Authors to grow in others, yet ſome of them are ſtrangers to us, and therefore imparted to furniſh the gardens of the curious.

The Time.

They keepe the ſame time to flower and ſeede that the others doe.

The Names.

The firſt is called *Eruca ſylveſtris* by *Matthiolus*, *Lobel*, *Dodonæus* and others: the ſecond is called by *Geſner in collectione ſtirpium Eruca ſylveſtris fœtida*, by *Tabermontanus Eruca paluſtris minor*, by *Lugdunenſis Eruca ſylveſtris*, and *Eryſimum verum*, and by *Gerard Sinapi paluſtre*: the third and fourth *Bauhinus* hath ſet forth by the ſame names are in the titles: the fift *Bauhinus* hath ſet forth in his *Matthiolus* and *Phytopinax* by the name of *Eruca paluſtris cærulea*, and in his *Pinax* by the name of *Eruca cærulea in arenoſis creſcens*: the laſt is the *Eruca ſylveſtris anguſtifolia* of *Lobel* which *Bauhinus* calleth *Eruca anguſtifolia Auſtriaca*.

The Vertues.

The wilde Rockets are hotter and dryer than thoſe of the garden, more ſtrong and effectuall alſo to encreaſe ſperme and Venerous qualities whereunto the ſeede is no leſſe effectualll than the herbe; it ſerveth alſo to helpe digeſtion, and to provoke urine exceedingly: the ſeede is uſed to cure the bitings of Serpents, the Scorpion, and the Shrew-mouſe, and other poyſons, and expelleth wormes and other noyſome creatures that engender in the body. *Pliny* writeth (but that it is too ſuperſtitious to relate) that if one gather three leaves of Rocket with their left hand, and bruiſe them, and drinke them in mede or honied water, it ſhall cure the jaundiſe, and that he that ſhould ſuffer whipping or beating, by drinking hereof in wine, ſhall not have any ſence thereof or feele any paine, but I wiſh that *Pliny* had beene a true relator hereof by his owne experience firſt, that others might have beleeved him the better: the herbe boyled or ſtewed, and ſome Suger put thereto helpeth the cough in children being taken often: the ſeede alſo taken in drinke taketh away the evill ſmell of the arme-holes or pits, and of the reſt of the body, and encreaſeth milke in Nurſes breaſts, and waſteth the ſpleene: the ſeede of wilde Rocket mixed with hony and uſed on the face clenſeth the skinne from ſpots, morphew, and other diſcolourings therein, and uſed with Vinegar taketh away freckles and other redneſſe hapning in the face or other parts, and uſed with the gall of an Oxe it amendeth foule ſcarres, blacke and blew ſpots, and the markes of the ſmall poxe reſtoring the skinne to its owne colour againe. As both theſe Rockets, and the former are forbidden to be uſed alone, in regard their ſharpneſſe doth fume into the head, there cauſing each and paine, ſo they are no leſſe hurtfull to hot and cholericke perſons, and to be forbidden them for feare of inflamming their bloud, and therefore for ſuch we may ſay a little doth but a little harme.

CHAP. III.

Barbarea. Winter Creſſes, or rather Winter Rocket.

UNto the Rocket (and not unto the Creſſes as the name hereof commonly giveth doth import) by the judgement of the beſt Herbariſts in theſe dayes pertaineth this *Barbarea*, whereof there are two ſorts more, although untill very lately one onely was knowne.

1. *Barbarea ſimplici flore.* Common Winter Rocket or Creſſes.

The Winter Creſſes or Rocket whether he will, hath divers ſomewhat large ſad greene leaves lying upon the ground torne or cut into divers parts ſomewhat like unto Rocket or Turnep leaves, & nothing like, Creſſes with ſmaller peeces next the bottome, and broade at the ends which ſo abide all the Winter (if it ſpring up in *Autumne* when it is uſed to be eaten either greene or ſtewed) from among which riſeth up divers ſmall round ſtalkes full of branches, bearing many ſmall yellow flowers of foure leaves apeece, after which come ſmall long pods with reddiſh ſeede in them: the roote is ſomewhat ſtringie, and periſheth ever after the ſeede is ripe.

2. *Barbarea flore pleno.* Double flowred Winter Creſſes.

The double flowred Winter Creſſes differeth not from the former but in the greatneſſe of the ſtalkes which are bigger and creſted, yet ſhorter in the leaves being an inch long cut in on the edges in the ſame manner, and in the flowers which are double and ſomewhat larger but yellow as the ſingle, and in the roote which periſheth not but abideth many yeares.

3. *Barbarea minor.* Small Winter Creſſes.

This ſmaller ſort hath blackiſh greene leaves ſomewhat jagged or torne on the ſides reſembling Moth-Mullein, the flowers are yellow and leſſe than the former, and ſo are the cods likewiſe: the roote hereof periſheth like the firſt.

The Place.

The firſt groweth oftentimes of its owne accord in gardens and in the fields alſo by the pathes and wayes ſide

in divers places, and by name in the next Paſture to the Conduit head behind *Grayes-Inne* that bringeth water to Mr. *Lambes* Conduit in *Holborne*: that with double flowers was found in the province of *Berne* among the *Switzers*, and the laſt in Gardens onely both with us and in *Germany*.

The Time.

They doe all flower in *May* and the ſingle ones doe ſeede in *Iune* and then periſh, but the double abideth greene both Sommer and Winter.

The Names.

It hath no Greeke name that I know except it ſhould be the Ψευδοβούνιον *Pſeudobunium* of *Dioſcorides* which *Lobel* thinketh ſhould rather be *Pſeudobunias*, for having ſhewed the difference betweene *Bunium* and *Bunias*, the one that is *Bunium* to bee *Bulbocaſtanum*, Earth Nuts, or Earth Cheſnuts, and *Bunias* the Navew: this herbe in the forme of the leaves flowers and ſeede is like unto the Turnip or the Navew, which is called Βούνιας *Bunias* or the wilde kindes of eyther: the Latines call it *Barbarea*, *Sanctæ Barbaræ herba*, *Naſturtium Barbaricum*, and of ſome *Naſturtium hybernum* from whence came our *Engliſh* name of Winter Creſſes, but as I ſaid being nearer both in forme and qualitie unto a Rocket then unto Creſſes, the moſt judicious have hereunto referred it. *Geſner in hortis* calleth it *Naſturtium paluſtre*, and *Lugdunenſis Eruca paluſtris*, *Camerarius Bunium adulterinum*, *Dodoneus Pſeudobunias*, *Anguilara Scopa regia*, and *Fuchſius Sideritis latiſſima*, *Tragus* maketh it his *Sinapi* 5. *genus*, and *Bauhinus* calleth it *Eruca lutea latifolia ſive Barbarea*: the ſecond *Bauhinus* onely hath written of and calleth it *Eruca lutea ſive Barbarea flore pleno*: the laſt *Lobel* calleth *Barbarea minor Herba Sancti Alberti Bononienſium*, and ſo doth *Cæſalpinius* alſo. *Bauhinus* putteth it among his ſorts of *Eryſimum* and calleth it *Eryſimo ſimilis lævis laciniata floribus luteis*. The *Italians* and *Spaniards* are ſcarſe aquainted herewith being more peculiar to theſe colder climates, The *French*, high and low *Dutch* and we doe follow the Latine names, ſome of Saint Barbary and ſome of Winter Creſſes, or as I ſayd before more properly to be called Winter Rocket.

1. *Barbarea ſimplex.*
Common winter Rocket or Creſſes.

The Vertues.

This is ſomewhat ſharpe in taſte and withall ſomewhat binding, whereby it may eaſily be knowne to bee hot and dry, and is profitable to provoke urine, and helpeth the ſtrangury and to expell gravell and the ſtone: it is alſo of good effect in the Scorbute or Scurvey, and may be uſed for it to very good purpoſe: it is alſo found by good experience to be a ſingular good wound herbe both to clenſe inward wounds, the juice or decoction of the herbe to be drunke, or outwardly applied to waſh fowle ulcers and ſores, clenſing them by the ſharpeneſſe and abating the dead fleſh growing therein, or hindering it from growing therein, and healing them by the drying qualitie: It is uſed as Rocket or Creſſes eaten in Winter when varietie of Sallets are not to be had with as great deſire and content as any other for that time.

CHAP. IIII.

Eruca marina. Sea Rocket.

OF the Sea Rockets there are three or foure ſorts, with notable differences as you may perceive in the ſucceeding Chapter.

1. *Eruca marina Anglica. Engliſh* Sea Rocket.

The *Engliſh* Sea Rocket (for ſo I call it for diſtinctions ſake, and that this ſort and none of the other groweth on our coaſts, although it grow in other countries alſo) hath divers ſtalkes, ſome trayling upon the ground others ſtanding more upright (but brought into Gardens it ſomewhat varieth the face both in ſtalkes and leaves) ſcatteringly ſet with ſmall long leaves thereon waved as it were on the edges like Groundſell or Rocket (but longer and leſſer in the Garden) at the toppes of the ſtalkes grow the flowers, of a pale purpliſh colour of the faſhion of the flowers of Raddiſh compoſed of foure leaves, after which come ſeede faſhioned like a wheate Corne (ſuch alſo it beareth in the Garden) but greater, which are ſomewhat ſpongie and not ſolid, not two joyned together as it is ſet downe to have by the Sea ſide, but every ſeede ſingle by it ſelfe.

2. *Eruca maritima Cretica. Candy* Sea Rocket.

The Sea Rocket of *Candy* hath divers ſhort and narrow rough greene leaves next the roote, cut and divided on the edges into ſmall parts: the ſtalkes are ſtraked and crooked about halfe a foote long bearing flowers at the toppes (which *Bauhinus* who giveth us the knowledge thereof hath not ſet downe) but if it be the ſame that *Lugduvenſis* ſetteth forth by the name of *Eruca maritima*, which as he ſaith *Myconus* ſent out of *Spaine* as I am verily perſwaded it is, it hath purpliſh flowers, and three ſquare pods with ſeede, and after them divers rough crooked and joynted pods three or foure inches long, containing ſmall reddiſh ſeede: the plant is hoary all over both ſtalkes and leaves.

3. *Eruca*

1. *Eruca marina Anglica.*
English Sea Rocket.

3. *Eruca Monſpeliaca ſiliqua quadrangula.*
Square codded Rocket.

3. *Eruca Monſpeliaca ſiliqua quadrangula.*
Square codded Rocket.

This ſquare codded Rocket hath the lower leaves ſmall, long and narrow, hairy, rough and waved or cut in on the edges like Groundſell or Rocket, from whence riſe two or three ſtalkes that are round, rough and reddiſh at the bottome ſet with ſome leſſer leaves, leſſe divided then thoſe below, and when it is full of flowers almoſt not at all: the ſtalkes are branched at the toppes bearing many ſmall yellow flowers of foure leaves a peece after which ſucceede ſmall ſquare ſmooth pods, hard when they are ripe, with a rough ſharpe point at the end, and open into two parts, with one browniſh ſeede lying in each part or ſide, and is turned like a ſnaile pointed at the ends, and ſharpe in taſte upon the tongue: the roote is ſomewhat thicke and white, with ſome fibres faſtned thereto.

4. *Eruca maritima Italica.* *Italian* Sea Rocket.

The *Italian* Sea Rocket hath ſome long and narrow leaves growing next to the roote, very much and finely cut into divers ſmall parts, having the ſtalke branched diverſly, and ſet with the like leaves but leſſer and leſſe divided ſtill up to the toppes, where the flowers being purpliſh conſiſting of foure leaves, ſtand one above another in ſmall huskes, with two points a peece wherein when the flowers are faded and gone ſtand ſmall pointed heads faſhioned like a Speares point wherein is contained a white kernell: the roote creepeth under ground with ſome ſtrings but periſheth after it hath borne ſeede.

The Place.

The firſt groweth on our owne Sea coaſts in many places both of *Kent* and *Suſſex* eſpecially, yet it is not proper onely to our coaſts but is found in the like places in divers Countries: the ſecond was ſent by *Honorius Bellus* from *Candy* unto *Bauhinus* as hee ſaith the dryed plant with ſeede thereto but no flowers, and therefore I could not expreſſe them but as I ſayd in the deſcription it is very probable to be the ſame that *Lugdunenſis* ſaith *Myconus* ſent from *Catalonia* in *Spaine* where it grew, to *Lyons*:

4. *Eruca maritima Italica.*
Italian Sea Rocket.

the third groweth about *Mompelier*: and the laſt about the Sea coaſts of *Italy*, both *Venice* and other places.

The Time.

They doe all flower and ſeede in the Sommer moneths, for they are all but annuall plants and are to be ſowen in Gardens in the ſpring of the yeare.

The Names.

The firſt is called by *Lobel Eruca marina Kakile Serapionis*, and ſo it is alſo by *Anguilara*, *Camerarius*, *Columna* and *Lugdunenſis*; the ſecond is called by *Bauhinus Eruca maritima cretica ſiliqua articulata*, and is likely as I ſaid to bee the ſame of *Myconus*, which *Lugduenſis* calleth *Eruca maritima* having three ſquare cods of ſeede which is a manifeſt difference from the former: the third is called alſo by *Bauhinus Eruca Monſpeliaca ſiliqua quadrangula echinata* which *Lugdunenſius* calleth *Sinapi echinatum*: the fourth is called by *Bauhinus Eruca maritima Italica haſtæ cuſpidi ſimile*, and withall maketh the *Kakile Serapionis*, the *Eruca maritima* of *Lugdunenſis*, and his *Naſturtium maritimum* to be all one with it, for which I can ſee no reaſon, in that having given the figure thereof in his *Prodromus*, every one may plainely ſee it to differ very much in the forme of the leaves from the other, it may well be his *Naſturtium maritimum* for thereunto it anſwereth very well as alſo unto his *Eruca cinerea* in ſome part that is in the leaves.

The Vertues.

The Sea Rocket is in the ſame degree of heate and dryneſſe with the wilde kinds but ſaltiſh and are effectuall for the ſame diſeaſes: moreover *Anguilara* ſaith that *Kakile* (which I call the *Engliſh* Sea Rocket) purgeth exceedingly, and *Myconus* affirmeth that his *Eruca Maritima* doth wonderfully helpe thoſe that are troubled with the Collick, and thoſe that are grieved with the ſtone or gravell in the Kidnies or Bladder, if they drinke the quantitie of foure ounces of the diſtilled water warme at a time.

CHAP. V.

Reſeda. Baſe wild Rocket.

BEſides the two ſorts of this kind of Rocket the greater and the leſſer ſet forth by ſundry Authors wee have ſome others which for their neare affinitie and likeneſſe are fit to be joyned and entreated of together.

1. *Reſeda major.* The greater baſe wilde Rocket.

This greater kind riſeth up with divers creſted bending ſtalkes about two foot high, ſet with many and much divided leaves thereon ſomewhat like unto the loweſt leaves of Rocket, of a piercing ſharpe ſent and taſte like unto Creſſes and many ſuch like leaves alſo buſhing together at the foot of them: at the toppes of the ſtalkes grow yellow flowers in long ſpikes thicke buſhing together, which opening by degrees at the bottome, ſpread themſelves farther in ſunder, and afterwards upon the ſaid ſhort footeſtalkes come ſmall skinnie cornered ſwollen cods turning downewards, wherein are contained very ſmall ſeede: the roote is long and wooddy with divers fibres thereat, and abideth many yeares.

1. *Reſeda major.*
The greater baſe wilde Rocket.

2. *Reſeda minor ſeu vulgaris.*
Common baſe wilde Rocket.

This other *Reſeda* groweth more upright and not ſo high, with whiter greene leaves, deepely cut in or torne on the edges, but each diviſion is broader then the former, the flowers are ſmall and yellow growing on ſuch ſpikes but ſhorter.

3. *Reſeda Linariæ foliis.* Narrow leafed baſe wild Rocket.

The ſtalke of this *Reſeda* is ſtraight and round, about a cubit high, parted into ſundry branches, compaſſed about with long and narrow greene leaves like thoſe of *Linaria* or Tode Flax: the flowers grow at the toppes of the branches ſpike faſhion, of a yellow colour, after which come cornered ſeede veſſels double forked at the toppes, full ſtored with pale coloured ſeedes.

4. *Reſeda alba minor.* Small white baſe wilde Rocket.

This ſmall *Reſeda* ſhooteth forth divers whitiſh greene ſtalkes not fully a foote high, bearing divers long and narrow hoary leaves leſſer then thoſe grow neare the ground, or at the foote of the ſtalke, which are ſomewhat broader but not leſſe hoary: the flowers are white growing on the like ſpikes many cluſtering together, with ſmall greene heads in the middle of every one, wherein afterwards there is ſmall blackiſh ſeede conteined: the roote is ſmall long and white with fibres adjoyning unto it.

5. *Reſeda affinis Phyteuma Monſpelienſium dicta.*
Loves plant of *Mompelier*.

The loweſt leaves of this ſmall plant are ſmall long and ſomewhat narrow, of a whitiſh greene colour, and very like to thoſe of Lambes Lettice, the others that grow afterwards and upon the ſtalks which are weake and tender, about halfe a

foote

2. *Reseda minor seu vulgaris.*
Common base wilde Rocket.

5. *Resedæ affinis Phyteuma Monspelienſium.*
Loves plant of *Mompelier.*

foote high and doe almoſt lie on the ground are cut in, ſome on the ſides a little, and others more divided at the ends reſembling a ſmall *Valerian* leafe; the flowers grow towards the toppes of the ſtalkes one above another, but not in any ſpike with a ſmall leafe at the bottome of every one, and are compoſed of divers white narrow leaves like threads, with many ſmall threds alſo in the middle ſet in greene full huskes, the heads of ſeede are cornered, broad above and ſmaller below, wherein is contained whitiſh ſeede with a ſhew of a hole or dent in every one of them: the roote is white and ſomewhat long, divided into ſundry ſmall ſtringes which die every yeare, and raiſing it ſelfe againe from the ſhed ſeede.

The Place.

The two firſt are commonly growing in our owne Land in divers waſte grounds, both neare *London* and further of: the others grow on the *Pyrenean* hills and about *Mompelier.*

The Time.

They doe all flower about *Iune*, and ſome of them all the Sommer long.

The Names.

Reſeda in *Latine a ſedandis doloribus collectiones & inflammationes diſcutere nomen traxit*: for it hath no Greeke name that I know: yet is thought by moſt to be that *Reſeda* of *Pliny* which he ſaith grew about *Ariminum*, for as *Camerarius in horto* ſaith, both the two former ſorts grow there now frequently: the firſt is called by *Lobel Reſeda maxima*, and *Reſeda major* by *Thalius* and *Tabermontanus*, *Reſeda lutea* by *Lugdunenſis*, by *Camerarius Reſeda recta*, by *Geſner in hortis Reſeda quæ Seſamoides majus Ghino*, *Seſamoides magnum*, by *Lacuna*, and *Seſamoides alterum* by *Cæſalpinus*, and *Pycnocomon* by *Anguilara*: the ſecond is called by *Lobel Reſeda Pliny Neotericorum Eruca peregrina Italica* and *Cantabrica*, by *Camerarius Reſeda ſupina*, by *Tabermontanus Reſeda latifolia*, by *Cæſalpinus Seſamoides primum*, and by *Columna Erucago vulgaris*: the third is deſcribed by *Bauhinus* by the name of *Reſeda linariæ folijs*, and by him thought to agree with the *Reſeda candida* of *Lugdunenſis*, and with the *Seſamoides Salmanticum alterum* of *Cluſius*: the fourth is called by *Bauhinus Reſeda alba minor*; and by him ſaid to be *Cluſius* his *Seſamoides parvum Salmanticum*, and ſo doe *Lobel*, *Tabermontanus* and *Lugdunenſis*; but as I noted before in the 77. Chapter of the Claſſis of Vulnerary herbes which is of the *Lychnides viſcoſæ*: *Bauhinus* hath much forgotten himſelfe in ſetting downe theſe ſmall *Seſamoides* of *Cluſius* making them there to be *Lychnides*, and here to be *Reſedas*, and therefore I have referred them to theſe, to whom in my judgement they better agree: the laſt is called by *Lobel Phyteuma Monſpelienſium*, and *Narbonenſium* by *Lugdunenſis*, *Seſamoides parvum* by *Lacuna*, and *Seſamoides tertium*, by *Cæſalpinus*, and as *Bauhinus* ſaith *Erucago Apula Columnæ*, but the deſcription thereof in *Columna* doth not fitly agree thereto in my opinion. *Gerard* calleth the two firſt ſorts (for he knew none of the reſt) in *Engliſh*, *Italian*, Rocket and Crambling Rocket, but I thinke it better to call them baſe wilde Rockets, in that being referred to the Rockets they are baſe and wilde herbes but clammer not.

The Vertues.

None of our later authours have mentioned any knowne properties, theſe plants are endued withall more than what may be gathered from the definition of the name which is to eaſe paines, and to diſcuſſe ſwellings and inflammations for *Pliny* his old wives ſpell or charme wee daine it not worthy the reciting, but the taſte thereof comming ſomewhat neare Rocket may induce ſome ſuch like propertie.

CHAP.

Chap. VI.

Naſturtium. Creſſes.

OF Creſſes there are divers kindes, and divers ſorts of every kinde, ſome are of the Gardens, ſome of the Fields or Medowes, ſome of the Water, ſome of the Hills or Mountaines. I ſhall forbeare to ſpeake in this place of thoſe that grow in the Water, having a Claſſis of water herbes among whom they ſhall be expreſſed: I will beginne with thoſe of the Garden, and make them the ſubject of this Chapter, yet I have in my former Booke given you the knowledge of that which is moſt common and beſt knowne, whoſe figure notwithſtanding I thinke not amiſſe to exhibite here againe to beare his fellowes company, and that thereunder the properties of the reſt may be comprehended.

1. *Naſturtium hortenſe latifolium Hiſpanicum.*
Great *Spaniſh* Creſſes.

The great *Spaniſh* Creſſes hath the firſt leaves ſmall like Baſill, among which riſeth up a ſtalke about a foote and a halfe high, ſet with larger leaves thereon without diviſion, but ſmally dented about the edges and pointed at the ends, every one ſtanding upon a long foote ſtalke, branched from the middle to the toppe with leſſer and narrower leaves, like to the toppe leaves of Garden Creſſes, from whence breake forth many white flowers ſet in ſpikes one above another, after which come browniſh ſeede in pouches like the other Creſſes, but much more bitter, and not ſo fiery ſharpe: the roote is ſmall and long periſhing every yeare, and therefore muſt be ſowen in the Spring, for although it will ſpring up quickly from the ſhed ſeed, yet it will not abide the cold of our Winters.

2. *Naſturtium hortenſe criſpum latifolium & anguſtifolium:*
Curl'd Creſſes with larger and leſſer leaves.

Curl'd Creſſes groweth like the ordinary Garden Creſſes, and differeth there from onely in the leaves which are of two ſorts, the one with broad leavs cut and roundly dented and curl'd about the edges, every one by it ſelfe on a long ſtalke: the other conſiſting of many ſmaller leaves ſet one againſt another upon a middle ribbe each part whereof is in the ſame manner cut in and curl'd as the other: the flowers are white like the common garden kinde, and ſo is the reddiſh ſeede likewiſe, and periſheth yearely after ſeede time as the others.

The Place.

The firſt as the title ſheweth came firſt out of *Spaine*, but the others are not knowne from whence their originals are.

The Time.

They doe neare follow the time that the other garden kinde doth, that is in *Iune* and *July*, and ſometimes later.

The Names.

The Greekes call it κάρδαμον ἀπὸ τῆς καρδίας *Cardamon quod cordatos faciat vel quod cor foveat*, and *in ſincope cardiaca plurimum valet*; others thinke it to be called κάρδαμον *quaſi* καρήδαμον *quod acrimonia & ignea vi præditum caput tentat*, and thereupon the Greekes had this proverbe ἔσθιε κάρδαμον, *ede Naſturtium quod in ſocordem ignavum, & hebetem dicebatur, propterea quod Naſturtio ineſſe credebant animi vigorem excitandi*, that is, Eate Creſſes to ſtirre up the ſpirits of thoſe that are dull and heavie: the *Latines* call it *Naſturtium a narium tormento*, as *Pliny* ſaith, ſome after the *Italians* call it *Creſſio hortenſis*: the *Arabians* call it *Naſ alchaf* or *Narf*; the *Italians Creſſione*, *Naſturtio*, and *Aigretto*: the *Spaniards Maſtuercos* and *Malpica*: the *French Creſſon de jardin*, *Creſſon alemois* and *Naſitort*: the *Germans Kerſſ* and *Kreſſicke*: the *Dutch Kerſen*; and we in *Engliſh* Creſſes. The firſt is ſet forth by *Tabermontanus* and *Gerard* who deſcribeth it untowardly enough, but by *Bauhinus* more fully and plainely giving a truer figure thereof likewiſe; it is uſually called with us *Naſturtium latifolium Hiſpanicum*: the other *Bauhinus* hath ſet forth and the figures of both ſorts, which are not extant in any other author.

Naſturtium hortenſe. Garden Creſſes.

The Vertues.

The common Garden Creſſes (in declaring the vertues whereof theſe other here ſpecified are included, being of the ſame propertie or very neare thereunto) is hot and dry in the fourth degree, eſpecially the ſeede, for the greene herbe by reaſon of the humiditie therein is more qualified, and therefore the people in many countries doe eate it either alone with butter or with Lettice and Purſlane in ſallets or otherwiſe, but the dried herbe commeth neare to the force of the ſeede, as *Galen* ſaith, who maketh it of the like faculitie and operation with Muſtard, both for the head and lungs to cut groſſe flegme and to expectorate it, as alſo in all other the properties of Rocket and Muſtard, both to provoake urine and to clenſe the raines and the bladder, to procure womens courſes, and to kill the birth and to ſtirre up Venery; yet *Pliny* ſaith it hindereth, but he was therein either much miſtaken, or the bookes are much falſified that ſo relate it. It is an enemy to the ſtomacke and troubleth the belly; ſome ſay it looſeneth the belly and purgeth it from viſcous humours; it helpeth the obſtructions of the liver and ſplene, and healeth all inward wounds, it driveth forth venome and poiſon; being taken with oyle it is beneficiall for the cough and ſhortneſſe of winde and the paines of the breaſt or cheſt: being chewed in the mouth it helpeth the

tooth-ach

1. *Naſturtium hortenſe latifolium Hiſpanicum.* Great Spaniſh Creſſes.

2. *Naſturtium hortenſe criſpum latifolium & anguſtifolium.* Curl'd Creſſes with broader and narrower leaves.

tooth-ach: the leaves bruiſed and applied take away all ſpots and markes of the body, helpeth the itch, and eaſeth the paines of the *Sciatica*, and of the loynes, draweth forth bones, ſplinters and thornes, ſtayeth the corroding and creeping ulcers: the ſeede chewed in the mouth helpeth the palſie in the tongue provoketh ſneeſing, raiſeth lethargicke perſons and ſuch as are drouſie and heavie by quickning their bloud and ſpirits: being boyled with vineger and applied to the kernells of the throate healeth the Kings evill, and healeth alſo the ſcabbes and ſores of the head if they be anointed with it and Gooſe greaſe mixed together: it ripeneth alſo plague ſores, and breaketh them, and taketh away the deformities of the nayles.

CHAP. VII.

Naſturtia pratenſia ſive Cardamines. Ladies ſmockes or Cuckow flowers.

UNto the kindes of Creſſes muſt of neceſſitie theſe herbes appertaine called Ladies Smockes, or Cuckow flowers, both for the neareneſſe in name in forme and qualitie whereof there are ſome varieties as ſhall be ſhewed here, yet that ſort which beareth double flowers, I have ſet forth in my former booke, which ſhall not be further entreated of here more than the figure, nor thoſe of the water, which are reſerved for another place.

1. *Naſturtium pratenſe majus ſive Cardamine latifolia.* Great Ladies Smockes.

The great Cardamine or Lady Smocks ſhooteth forth divers long ſtalks of winged leaves, that is many together, ſomewhat broad and round tender darke greene leaves ſet one againſt another upon a middle ribbe, the greateſt being at the ends, among which riſe up divers tender weake round greene ſtalkes ſomewhat ſtraked, with much ſmaller and longer leaves thereon, very like the ſmalleſt divided leaves of Garden Creſſes, at the toppes whereof ſtand divers flowers made of foure leaves apeece, ſomewhat large, and almoſt like a Stocke gilloflower, but rounder and not ſo long neither, whitiſh or ſomewhat daſht over with bluſh, and many times but at the edges onely, each of them ſtanding in a greene huske, after which come ſmall powches containing reddiſh ſeede ſomewhat ſharpe and biting in taſte as the herbe it ſelfe is alſo, comming neare to Creſſes: the roote is compoſed of many white threads or fibres.

2. *Cardamine altera minor.* Small Ladies Smockes.

This is in all things like the former but ſmaller in every part not buſhing with ſo many leaves or ſtalkes, the poddes of ſeede being ſomewhat longer, than in the former.

3. *Cardamine altera parvo flore.* Small flowred Ladies Smockes.

The leaves of this *Cardamine* are moſt uſually ſmaller and longer, and yet round ſometimes alſo, growing in the

Cardamine flore pleneo.
Double flowred Ladies Smocks.

2. *Cardamine altera minor.*
Small Ladies Smocks.

the same manner that the others doe: the flowers also are like them but smaller, and the pods of seede some what longer.

4. *Cardamine odorata granulosa,* Tuberous rooted sweete Ladies Smockes.

The greatest difference in this from the second sort here expressed consisteth first in the rootes, which among the small fibres have many small kernelly rootes growing, and then the flowers, which although they bee white or blush like them in colour and forme, yet smell sweeter then they all together or any of the rest.

5. *Cardamine minor laciniatis foliis.* Small jgged Ladies Smockes.

The chiefest difference in this from the third sort resteth in the leaves which are more jagged then any of the former comming somewhat neare unto the forme of the lower leaves of the Garden Cresses the flowers are white and small like that sort.

The Place.

The three first are found in divers places of our Land in moist Medowes, and neare unto brookes sides or the small Rilles of water that passe through the low grounds, the others are of *Germany*.

The Time.

They flower somewhat early in the Spring about *Aprill* or *May* at the farthest, and abide with the lower leaves all the Winter.

The Names.

They are called by divers writers *Cardamine* as deduced from *Cardamon Cresses* (as *Helleborine* from *Helleboras*) because they are like thereunto, some also call it *Sium alterum* and *Nasturtium aquaticum*, but there are other herbes more properly so called, and therefore others call them *Nasturtium pratense*, as *Tragus* and *Gesner*, *Fuchsius* calleth it *Nasturtium agreste*, and *Lonicerus Sylvestre*, *Cordus* upon *Dioscorides Lepidium minus*, *Brunfelsius* and *Dodonæus Flos cuculi*: from the *Germans Gauch blumen*, whereby they so call them, *Matthiolus Sysimbrium aquaticum alterum*, and so doth *Tabermontanus*: *Lacuna* and *Lugdunensis* call them *Sysimbrium Cardamine*, *Fuchsius Hiberis*, and *Thalius Iberis*, and *Agriocardamum sive Cardamantica Nasturtij folio*, *Clusius Cardamine altera* and so doth *Lobel*, *Besler in Horto Eystetensi* calleth it *Nasturtium aquaticum simplici flore*, and *Bauhinus Nasturtium pratense magno flore*; Of the third and of the last *Bauhinus* onely doth make mention, and of the fourth *Lugdunensis*. The *French* call them *Passerage sauuage*, the *Germanes* as I said *Gauch blumen* (yet both they and we have another *Flos cuculi*, Cuckowflower differing from this, accounted among the Campions as I have declared in my former Booke) the *Dutch Winter Kersse* and *Cockoecks bloemen*, and we in *English* Cuckow flowers and Ladies Smockes.

The Vertues.

These herbes are seldome used eyther as sawce, or sallet, or in Physick, but more for pleasure and to decke up the Garlands of the country people, yet divers have reported them to be as affectuall in the Scorbute or Scurvey, as the Water Cresses, and may serve in stead of them where they are wanting and not to be had.

CHAP.

CHAP. VIII.

Naſturtia Montana ſive Cardamine Alpina. Mountaine Ladies Smockes.

THere is another kinde of Creſſes to be entreated of which grow upon mountaines, hills, and dryer grounds which ſhall follow here, yet one of them I have declared in my former book called *Cardamine Alpina trifolia*, which ſhall not be deſcribed here againe although I will give you the Figure thereof.

1. *Cardamine tenuifolia montana.* Thin leafed mountaine Ladies Smocks.

This mountaine *Cardamine* or Ladies Smocks hath divers long winged ſtalkes of ſmaller and narrower leaves then in the former, a little dented about the edges, from whence ſpring up ſundry ſtalkes with ſmaller leaves on them to the toppes, where ſtand many ſmall yellow flowers in cluſters, and afterwards ſmall long pods with ſmall yellowiſh ſeede in them, which opening themſelves fall out: the roote is ſmall and fibrous creeping upon the ground.

2. *Cardamine Alpina minor Reſedæ folijs.* Small mountaine Ladies Smockes.

This ſmall *Cardamine* ſendeth forth from a ſmall long white roote divers weake and leaning ſtalkes, ſome a little branched and others not at all, ſet in many places with long ſtalkes of leaves divided into three foure or five parts or round leaves, ſomewhat like unto thoſe of *Reſeda*, the baſe wild Rocket, the flowers that ſtand at the toppes are ſmall and white, and afterwards give long and ſlender round pods an inch and a halfe long.

3. *Cardamine Alpina midia Cluſii.* *Cluſius* middle ſiſed Ladies Smockes.

The leaves of this mountaine kind lye in a round compaſſe upon the ground, very formally being two inches long, made of divers ſmall leaves like unto the other Ladies Smockes, but of a middle ſiſe and more rough and hairy then the other, of a grayiſh colour on the upper ſide and greene underneath, the ſtalke riſeth to bee halfe a foote or more high, bearing many white flowers like the others at the toppes, where afterwards ſtand long pods with ſeede in them; the roote is white and fibrous.

4. *Cardamine Alpina minima.* The ſmalleſt mountaine Ladies Smockes.

This is a very ſmall and tender plant whoſe ſtalkes are not much above an inch long, bearing umbells or tufts of ſmall white flowers on them of foure leaves a peece, the greene leaves are very ſmall, five or ſeven, ſet upon a ſmall footeſtalke on both ſides of a middle ribbe as in the reſt, very ſharpe in taſte.

5. *Cardamine Alpina inſipida.* Vnſavory Ladies Smockes.

This hath ſmall long leaves rough and hairy and jagged like the field Muſtard, but without any ſharpeneſſe or taſte at all in them: the ſtalke is ſmall and hairy bearing ſmall white flowers, and afterwards ſmall cornered and prickly huskes with very ſmall ſeede therein: the roote is ſmall and long with few fibres thereat.

6. *Plantula Cardamines alterius æmula Cluſii.* The Ladies Smocke-like plant.

This ſmall plant hath ſix or ſeven ſmall leaves lying upon the ground, not much unlike the leaves of the ſmall wilde Daiſie, but much more tender, having a little ſharpeneſſe in them: from the middle whereof riſeth up a ſmall tender ſtalke an hand breadth high or little more, with very few and they ſmaller leaves and ſmall

Cardamine Alpina trifolia.
Mountaine three leafed Ladies Smocks.

2. *Cardamine Alpina minor Reſedæ folijs.*
Small mountaine Ladies Smocks.

white

6. *Plantula Cardamines alterius æmula Clusij.* The Ladies Smocks-like plant.

7. *Nasturtium petræum.* Rocke Cresses.

white flowers at the toppes, after which commeth pods which are somewhat larger and greater then the smalnesse of the plant might seeme to give, with small reddish seede therein somewhat sharpe in taste: the roote creepeth under ground shooting forth in sundry places.

7. *Nasturtium petræum bursæ pastoris folio.* Rocke Cresses.

In the leaves of this Cresse consisteth the greatest difference from the others which is small and jagged or cut in on the edges like the leaves of Shepherds purse, for the flowers are small and white, and the seede vessells small and flat like to *Thlaspi* or Treakle Mustard.

8. *Nasturtium pumilum vernum.* Small Cresses of the Spring.

The first leaves of this small plant are somewhat round, two or three being set one against another about a middle ribbe as the others are, but those that follow are somewhat longer and more in number: the stalke is scarse an handbreadth long, bearing such small white flowers that they are scarse discerned, after which come very small short and round pods with very small yellowish seede, the roote is small and fibrous: the whole plant is sharpe in taste.

9. *Nasturtium Alpinum capsula Nasturtij hortensis.* Mountaine Crēsses.

This mountaine Cresses hath small and narrow thicke leaves smaller then the nayle of ones hand, and stalkēs not above two inches high, with such small white flowers on them, and somewhat large powches like to those of Garden Cresses: the roote is somewhat wooddy and fibrous.

10. *Nasturtium Alpinum Bellidis folio majus.* Daisie leafed mountaine Cresses.

The stalke hereof is smooth and round about a cubit high, branched from the very bottome, the leaves are very thin but of foure inches long, somewhat like to Daisie leaves, those on the stalkes are somewhat waved about the edges and without footestalkes compassing the branches at the bottomes, the flowers are white and stand on a long spike one above another of six inches long, after whom succeede long and slender pods three inches long, containing within them flat round reddish seede.

11. *Nasturtium foliis Barbaræ.* Winter Rocket-like Cresses.

The stalkes of this Cresse are very small, tender and bowing downewards somewhat hairy and divided into some branches of an handbreadth long, some twise that length, and some a cubit high, having many very small and slender greene leaves lying at the bottome of them, divided after the manner of the Winter Cresses or Winter Rocket as I called it before, but with fewer divisions, those on the stalkes are fewer, smaller and lesse divided; the flowers are very small and white, and the pods very slender and long: the roote is small white and threddy.

The Place.

Most of these plants grow upon the Alpes and other hills and mountaines in *Germany*, yet some of them in *Naples* as *Columna* hath made mention.

The Time.

Some of them flower earlier in the Sping then others, and some later.

The Names.

Columna of *Naples* calleth the first *Sium alterum aquaticum luteum sive Cardamine tenuifolium montanum*, and *Bauhinus Nasturtium montanum luteum*: the second is called by *Bauhinus Nasturtium Alpinum minus Resedæ folio*: the third *Clusius* calleth *Cardamine Alpina media*, and *Bauhinus Nasturtium Alpinum minus foliis in orbem sparsis*: the fourth is called by *Clusius Cardamine Alpina minima*, by *Gesner in Epistolis* as *Clusius* mentioneth it *Nasturtiolum* and *Lugdunensis Thlaspi montanum minimum*, by *Columna Cardamine pusilla saxatilis montana discoides*, and by *Bauhinus Nasturtium Alpinum tenuissime divisum*: the fift is called by *Columna Cardamine Alpina insipida*, and

and by *Bauhinus Naſturtium Alpinum inſipidum*: the ſixt is called by *Cluſius Plantula Cardamines alterius æmula & Sinapi pumilum Alpinum*, and by *Bauhinus Naſturtium Bellidis folio minus*; the ſeventh is called by *Tabermontanus* and *Gerard Naſturtium petræum*, and by *Bauhinus Naſturtium petræum foliis burſæ paſtoris*: the eight is called by *Bauhinus Naſturtium pumilum vernum*: the ninth is called by *Bauhinus Naſturtium Alpinum capſulæ Naſturtij hortenſis*: the tenth and laſt he alſo calleth as they are in their titles.

The Vertues.

There hath not beene any eſpeciall triall made of any of theſe herbes that I know, but moſt of them being ſomewhat ſharpe in taſte, they are adjudged to be neare of the ſame qualitie with the former, or rather ſtronger in that they are mountainous plants, but I have nothing to affirme for certaine, and therefore let this ſuffice untill wee can ſay more of them.

CHAP. IX.

Naſturtia ſylveſtria. Wilde Creſſes.

THere is a wilde kinde of Creſſes yet to be handled whereof there are not many ſorts, one of them is to be found almoſt in every field, which although it be accounted a very foule weede in a garden, yet it is not amiſſe as I thinke to place it with the reſt.

1. *Naſturtium ſylveſtre Oſyridis folio.* Narrow leafed white Creſſes.

This wilde Creſſe bringeth forth many ſmall round and hard ſtalkes, with divers ſmall round and narrow leaves ſet without order thereon, branched from the middle upward into many parts, at the toppes come forth a number of ſmall white flowers (yet ſome have beene found with yellow flowers) one ſtanding above another ſpike faſhion, after which appeare huskes containing ſmall ſeede: the roote is wooddy and periſheth after ſeede time.

1. *Naſturtium ſylveſtre Oſyridis folio.*
Narrow leafed wilde Creſſes.

2. *Naſturtium ſylveſtre Valentinum.*
Spaniſh wilde Creſſes.

Spaniſh wilde Creſſes groweth up with a round greene, rough, and hairy ſtalke about a foote high ſpreading into branches from the very ground at every joynt whereof ſtand long winged leaves very much divided like unto the ordinary garden Creſſes but yet more ſmally parted and ſharpe in taſte like Creſſes: the flowers are many, and of a pale whitiſh yellow colour ſtanding in long ſpikes at the toppes, and afterwards ſmall ſhort powches divided into two parts which ſtand not upright but hang downewards wherein is contained ſmall reddiſh ſeede like unto Creſſes: the roote is long and ſlender, and periſheth every yeare.

3. *Sophia Chirurgorum ſive Pſeudonaſturtium ſylveſtre.*
Flixe weede.

There is no doubt but that this herbe pertaineth to the family of wilde Creſſes, although a baſtard ſort of them riſing up with a round upright hard ſtalke foure or five foote high ſpread into ſundry branches, wherein grow many grayiſh greene leaves very finely cut and ſevered into a number of ſhort and almoſt round parts, the flowers are very ſmall and yellow growing ſpike faſhion, after which come very ſmall long pods, with verie ſmall yellowiſh ſeede in them: the roote is long and wooddy periſhing every yeare.

Whereof there is an other ſort with ſomewhat broader leaves and in no other thing differing: they have a ſtrong evill ſavour being ſmelt unto, and are of a drying taſte.

The Place.

The firſt and the laſt grow wilde in the fields by hedge ſides and wayes, and among rubbiſh and many other places: the ſecond was found onely in the kingdome of *Valentia* in *Spaine*.

The Time.

They flower and ſeede quickly after, namely in *Iune* and *Iuly*.

The Names.

The firſt is *Thlaſpidij genus*, and *Naſturtium 5. Tragi*, *Thlaſpi anguſtifol.* of *Fuchſius* and *Lugd.* *Thlaſpi minus hort. vulg. Oſyridis folio acerrimũ album & luteum* of *Lobel*, *Naſturtiũ ſyl.* of *Thalius*, *Burſa paſtoris minor* of *Brunfelſius*, and *Naſturtium ſylveſtre Oſyridis folio* of *Bauhinus*, and may in my minde be accounted a *Thlaſpi* much better yet participateth of both: the ſecond is called by *Cluſius Naſturtium ſylveſtre Valentinum*, and ſo doth *Lugdunenſis* in following him; but *Lobel* in altering that title called it *Eruca Naſturtio cognata tenuifolia*, and is reprehended by *Cluſius* for ſo doing; by *Lugdunenſis* alſo *Eruca cinerea*, as *Bauhinus* thinketh, who maketh it alſo to be the *Iacobæa marina*, as is before ſaid, and called this *Naſturtium ſylveſtris Erucæ folio*: the laſt is called by ſome *Pſeudonaſturtium ſylveſtre*, by *Fuchſius* and *Geſner in hortis Naſturtium ſylveſtre*, by *Tragus Seriphium Germanicum*, and by *Lonicerus Seriphium abſinthium* (but very erroniouſly not having any affinitie with Wormewood) by *Dodonæus* in his *French* Booke, by *Geſner in hortis*, by *Cordus*, *Lugdunenſis*, *Thalius* and *Tabermontanus Thalietrum* or *Thaliſtrum* but not truely: but by *Dodonæus* in his Latine Booke, by *Lobel* and *Gerard Sophia Chirurgorum*, by

2. *Naſturtium ſylveſtre Valentinum.*
Spaniſh wilde Creſſes.

3. *Sophia Chirurgorum.*
Flixeweede.

which name it is now generally called and knowne, by *Cæſalpinus Accipitrina*, who maketh two ſorts thereof, as *Tabermontanus* doth of his *Thalictrum*, *viz. latifolium* and *anguſtifolium*, *Bauhinus* calleth it *Naſturtium ſylveſtre tenuifolium diviſum*. *Lobel* putteth a doubt whether it be not the *Eruca Gelatina* of the *Italians*: the *Germanes* call it *Wellſamen* as they doe Wormeſeed, and *Sophiakraut* after the *Latine*; the *Dutch Fiecrayt*, and wee in *Engliſh* Flaxeweede from the effect.

The Vertues.

The two ſorts of wilde Creſſes are neare the qualities of the other Creſſes; but both the herbe and the ſeede of Flixeweede is of excellent uſe to ſtay the fluxe or laske of the belly being drunke in water, or water wherein ſome gads of ſteele being heated have beene oftenquenched, and is found alſo no leſſe effectuall than Plantane or Comfrye for the ſaid purpoſe, and to reſtraine any other fluxe of bloud in man or woman, to conſolidate alſo broken bones, or out of joynt; the juyce thereof drunke in wine, or the decoction of the herbe drunke doth kill the wormes in the ſtomacke or belly, as alſo the wormes that grow in putride and filthy ulcers, and made into ſalves doth quickly heale all old ſores how foule or malignant ſoever they be: the diſtilled water of the herbe worketh the ſame effect although ſomewhat weaker yet is a faire medicine, and more acceptable to be taken.

CHAP. X.

Sinapi. Muſtard.

THere be divers that make ſome of the Rockets to be kind of Muſtard as you have heard before, and there be many alſo that make ſome kindes of Muſtard to be Rocket: I will endeavour as neare as I can to give each their due title and place, yet of theſe kindes I have in my former Booke ſet forth that which is moſt frequently uſed to make ſawſe in this Land, whereof I ſhall not neede to ſpeake againe.

1. *Sinapi ſativum Rapi folio.* Broad leafed Muſtard.

This Muſtard hath large and broad rough leaves very much jagged with uneven and unorderly gaſhes, ſomewhat like a Turneppe leafe but leſſer and rougher; the ſtalke riſeth to be more than a foote high and ſometimes two, being round, rough, and branched at the toppe, bearing ſuch like leaves thereon as grow below, but leſſer and leſſe divided, and divers yellow flowers one above another at the toppes, after which come ſmall rough pods with ſmall lancke flat ends, wherein is contained round yellowiſh ſeede greater than Turneppe ſeede, ſharpe, hot, and biting upon the tongue: the roote is ſmall, long and woody when it beareth ſtalkes and periſheth every yeare.

2. *Sinapi ſylveſtre minus.* Small wilde Muſtarde.

This Muſtard is ſomewhat leſſer than the former not riſing above a foote high with ſmall jagged leaves more

more orderly placed somewhat like those of the Shepheards purse, but more smally gashed, the flowers are yellow and the seede browniſh like the former but not ſo ſharpe.

3. *Sinapi parvum Monſpelienſe.* Small Muſtard of *Mompelier.*

This ſmall Muſtard is the leaſt of them all growing not above a ſpanne high, with ſmall bending branched ſtalkes and ſmall pale yellowiſh flowers at the toppes, which afterwards give ſmall long and ſlender rough pods winged on the ſides or edges, with very ſmall ſeede therein: the lower leaves are ſomewhat broad, cut into many parts, but thoſe on the ſtalkes have very ſmall cuts leſſer than the ſmalleſt leaves of Rocket ſomewhat hot and ſharpe in taſte.

1. *Sinapi ſativum Rapifolio.*
Broad leafed Muſtard.

2. *Sinapi ſylveſtre minus.*
Small wilde Muſtard.

4. *Sinapi agreſte Neapolitanum.*
Wilde Muſtard of *Naples.*

This *Neopolitane* Muſtard from a ſmall whitiſh fibrous roote ſhooteth forth many rough greene leaves cut into divers parts, ſomewhat like unto the leaves of the greater Celandine, but leſſer and more pointed at the ends: the ſquare ſtalke is divided into ſundry branches, bearing at the toppes divers ſmall purpliſh flowers conſiſting of foure leaves apeece ſet together as it were in an umbell or tuft, after which riſe ſmall pods of two inches long a peece, with yellowiſh ſeede within them, which quickly breake their veſſells and ſpill, not onely by ones touch, but by the ſhaking of the winde, ſo that it is hard to gather the ripe ſeede.

5. *Sinapi marinum Egyptium.*
Sea Muſtard of *Egypt.*

I call this a Muſtard (ſaith mine Author) becauſe it hath larger leaves than Rocket, and might ſeeme to be the *Eruca maxima Miconi* of *Lugdunenſis*, but hath not any bitterneſſe therein as his hath: nor is it the *Kakile Serapionis* commonly called *Eruca marina* which hath a nitrous taſte in it when as this hath a very ſharpe taſte: the roote hereof is long, white, ſlender and wooddy; having one or two reddiſh round ſtalkes, not ſtanding upright but a little bending, branching forth into other, with a few winged leaves thereon, that is made of many fine long ſappie leaves on a ſide, a little dented about the edges, in both colour and ſmell, comming neareſt to Rocket; at the toppes of the ſtalke come forth blewiſh flowers in faſhion of Stocke-Gillowflowers which turne into ſmall long pointed pods,

5. *Sinapi marinum Ægyptium.*
Egyptian Sea Muſtard.

contai-

containing ſmall ſmooth round ſeede of a very ſharpe taſte and ſmelling like Rue. This is very like the *Eruca cærulea* ſet forth before.

The Place.

The firſt is not found wilde with us but in Gardens onely, but the ſecond, as well as that which is ſpoken of in my other booke, are found often in the borders of fields, as alſo in the low rilles and furrowes of them; the other three are ſtrangers to us, the one being of *Mompelier*, the other of *Naples*, and the laſt of *Egypt*.

The Time.

All theſe Muſtardes are but annuall plants flowring in *July*, and their ſeede ripe in *Auguſt*.

The Names.

It is called in Greeke νᾶπυ *Sinapi*, and ſo doe the *Latines* call it alſo, and *Sinapis*: but *Athenæus* ſaith that the *Athenians* called it νᾶπυ, and *Ariſtophanes* in *Equiti* ſaith of *Cleomenes* when he was angry,

Κάβλεψε νᾶπυ, κ᾽ μέτωπ᾽ ἀνέσπασεν.
Conſpexit Sinapi & frontem contraxit.

The *Arabians* call it *Cardel*, the *Italians Senape*, the *Spaniards Moſtarde* and *Moſtaza*, the *French Senue* and *Mouſtarde*, the *Germanes Seneff* and *Senff*, the *Dutch Moſtaerte*, and we in *Engliſh* Muſtard. The firſt is called of *Lobel Sinapi ſativum Erucæ aut Rapifolio*, of *Cordus* upon *Dioſcorides*, and of *Lugdunenſis Sinapi hortenſe*, of *Dodonæus Sinapi ſativum prius*, of *Camerarius Sinapi album* differing from *Eruca ſemine albo*, of *Bauhinus Sinapi rapifolio*, *Sinapi Dioſcoridis & Theophraſti*, *Sinapi alterum Plinij*: the ſecondis called by *Lobel Sinapi ſylveſtre minus burſæ paſtoris folio*, by *Dodonæus* and *Lugdunenſis Sinapi ſylveſtre*, and is the third *Sinapi* of *Matthiolus*, *Durantes*, and *Cæſalpinus*, *Tragus* calleth it *Eruca ſive Rucula marina minor*, and *Sinapi novum*; *Fuchſius Eruca ſativa*, *Turner Eruca hortenſis*, and *Geſner in hortis Eruca ſylveſtris*: the third is called by *Bauhinus Sinapi parvum ſiliqua aſpera*: and the fourth *Columna* calleth *Sinapi alterum agreſte noſtras*: and *Bauhinus Sinapi umbella purpurea*: the laſt is ſo ſo called by *Alpinus* as is in the title.

The Vertues.

Muſtard ſeede eſpecially the common ſort is hot and drie in the fourth degree (but the white ſeede and the other ſmall ſorts are not ſo hot) and hath the vertue of heating, diſcuſſing, rarefying and drawing forth ſplinters of bones or other things out of the fleſh. The condiment or ſawce is of great uſe, for in a manner the whole encreaſe of the ground is ſpent thereabout to ſeaſon or ſharpen the meats, both of fiſh and fleſh that are eaten either by the rich or poore: the ſaid Muſtard is of good effect to bring downe womens courſes, and for other hyſtericall diſeaſes, and for thoſe that are Epilepticke or Lethargicke, that is troubled with the falling ſickneſſe or lethargie, drouſie, forgetfull, evill, to uſe both inwardly and outwardly to rubbe the noſtrills, the forehead and temples, to warme & quicken thoſe dull ſpirits that are as it were aſleepe or almoſt dead; for by the fierce ſharpeneſſe it pierceth to the braine and purgeth it by ſneeſing and drawing duwne rheume & other viſcous clammy humors which by their reſidence doe much offend, or by their diſtillation upon the lungs and cheſt procure coughing, and therefore with ſome honny added thereto doth much good therein. Our ancient, forefathers even the better ſort in the more ſimple, and as I may ſay the more healthfull age of the world, were not ſparing in the uſe hereof, for without doubt they found it much conducing to their health by warming the ſtomacke and helping digeſtion, by clenſing the braine, lungs and breaſt of rheume and flegme: but now adayes it is ſeldome uſed by their ſucceſſours being accounted the clownes ſawce, and therefore not fit for their tables; but is transferred either to the meany or meaner ſort, who therefore reape the benefit thereof. The decoction of the herbe, but the ſeede is the more uſuall and effectuall made in wine and driuke provoketh urine, reſiſteth the force of poiſon, the malignitie of Muſhromes, and the venome of the Scorpion or other venemous creatures, for it ſuffereth not the virulencie thereof to pierce to the heart, and vitall ſpirits, thereby to overthrow life, but maſtereth it in the way if it be taken in time: the ſame alſo taken before the fits of agues doth by warming the bloud and ſpirits, keepe backe and leſſen the cold fits, thereby altering the courſe and curing the diſeaſe: the ſeede alſo taken either by it ſelfe or with other things, either in an Electuary or drinke doth mightily prevaile to ſtirre up bodily luſt, being taken alſo in the ſame manner it helpeth the ſpleene and paines in the ſides and gnawings in the bowels, and uſed as a gargle, it helpeth the *Vvula* or pallate of the mouth when it is fallen downe and faſteneth it, and alſo diſſolveth the tumours & kernells about the throate in the Kings evill, eſpecially if it be alſo applied outwardly thereto: being chawed in the mouth it oftentimes helpeth the tooth-ach: the outward application hereof upon the pained place of the *Sciatica* doth much helpe to diſcuſſe the humours, and to eaſe or leſſen the paines, as alſo for the goute and other joynt-aches, and is much and often uſed to eaſe paines in the ſides or loynes, the ſhoulders or other parts of the body, upon the applying thereof to raiſe bliſters, and by drawing the paines to the place from the inward or more remote, cureth the diſeaſe or diverteth it to thoſe outward places where locall medicines may helpe: it is alſo uſed to helpe the falling of the haire: the ſeede bruiſed mixed with hony and applied, or made up with waxe, taketh away the markes and blacke and blew ſpots and bruiſes of beatings or the like, the roughneſſe or ſcabbedneſſe of the skin in any place, as alſo the leproſie, and lowſie evill: it helpeth alſo the cricke in the necke, or that diſeaſe when one cannot turne their heads, but they muſt turne their whole body with it. The diſtilled water of the herbe when it is in flower, is much uſed both inwardly to drinke to helpe in any the diſeaſes aforeſaid, or to waſh the mouth for the *Vvula*, or the kernells and tumours of the throate, but outwardly alſo for the ſcabbe, itch, or the like infirmities, and clenſeth the face and skinne from freckles, ſpots, morphew, or other deformities thereof. The *Italians* uſe to keepe a drie condiment or ſawce made of Muſtard ſeede to uſe upon all occaſions, ſuddenly made fit to be eaten, which it is likely they learned from *Dioſcorides* who taught his to keepe Rocket ſeede good for a long time, by beating it and making it up with vinegar and milke into balles to be dried: for they much after the ſame manner appoint two ounces of Muſtard ſeede to be taken, and halfe an ounce of good Cinamon well beaten to be made up into balles or cakes with hony and vinegar, which being dried in the Sunne are to be kept untill uſe be to be made thereof, which then relented with a little vineger is made into ſawce preſently, very delicate and pleaſing to the palate and ſtomacke.

CHAP.

CHAP. XI.

Irio sive Eryſimum. Hedge Muſtard.

HEre are divers ſorts of this Hedge Muſtard more knowne at this time then formerly hath bin, being found out by divers diligent and experienced ſearchers of herbes, as you may perceive in the ſucceeding diſcourſe.

1. *Irio ſive Eryſimum vulgare.* The common wilde Hedge Muſtard.

The common *Eryſimum* groweth up uſually but with one blackiſh greene ſtalke, tough or limber, eaſie to bend but not to breake, branched into divers parts, and ſometimes with divers ſtalkes, ſet full of branches whereon grow long rough or hard rugged leaves very much cut in or torne on the edges into many parts, ſome bigger and ſome leſſer, of a durtie greene colour: the flowers are ſmall and yellow that grow at the tops of the branches in long ſpikes flowring by degrees ſo that continuing long in flower, the ſtalkes will have ſmall round cods at the bottome, growing upright and cloſe to the ſtalke, while the toppe flowers yet ſhew themſelves, in which are contained ſmall yellow ſeede, ſharpe and ſtrong as the herbe it ſelfe is alſo: the roote groweth downe ſlender and wooddy, yet abiding and ſpringing therefrom every yeare.

2. *Eryſimum alterum ſiliquis Erucæ.* Broad leafed hedge Muſtard.

This hedge Muſtard riſeth up with two or three darke greene ſtalkes, ſomewhat like the former but not ſo much branched, ſet on all ſides with large darke greene leaves, cut into three or foure parts, with almoſt equall gaſhes on each ſide, but the end is the largeſt, ſomewhat unevenly waved or dented about the edges thereof: the flowers are ſmall and yellow, yet greater then the former, whoſe ſpikes are not ſo long, neither doe the long and round pods of yellow ſeede ſtand ſo cloſe to the ſtalkes, nor are ſo ſmall but ſhorter like to thoſe of Rocket: the roote is not ſo long or wooddy but more fibrous continuing but a yeare.

3. *Eryſimum verum ſive montanum.* The true hedge Muſtard.

The leaves of this *Eryſimum* are of a freſher greene colour then either of the former, ſmaller alſo, and cut in on both ſides into more but ſmaller parts, reſembling the diviſions on the leaves of Dandelion but very ſmall, each part or corner looking downewards, from among which riſe up ſometimes two or three ſtalkes, but more uſually but one, round, and about halfe a yard high, thicke ſet with ſuch leaves but ſmaller and full of branches to the toppes, all along which come forth very ſmall yellow flowers with ſmaller leaves with them, after which follow whitiſh yellow ſmall cods growing cloſe to the ſtalkes, conteining within them ſmall yellow ſeede, nothing ſo ſtrong or ſharpe as the firſt, yet ſomewhat quicke upon the tongue: the roote is ſmall and periſheth after ſeede-time, but by ſowing it ſelfe never miſſeth to be in the ground where it hath once ſeeded.

4. *Eryſimum latifolium Neapolitanum.* Broad leafed hedge Muſtard of *Naples.*

This *Neapolitane* hedge Muſtard hath many ſmall long and ſmooth greene leaves lying in a compaſſe upon the ground, divided or cut after the manner of the wilde Rocket (which we call our ordinary Garden Rocket) but with ſmaller and leſſer diviſions, the middle ribbes being white, the ſtalke that riſeth from among them, for it

1. *Irio ſive Eryſimum vulgare.*
The common wilde hedge Muſtard.

3. *Eryſimum verum ſive montanum.*
The true hedge Muſtard.

4. *Eryſimum latifolium Neapolitanum.*
Hedge Muſtard of *Naples.*

6. *Eryſimo ſimilis hirſuta planta.*
An hairy hedge Muſtard with uncut leaves.

ſeldome beareth more then one is about two foote high, ſet with the like leaves but leſſer and leſſe divided up to the toppe, and with longer ends more pointed, of a ſtrong ſent and bitter ſharpe taſte, the flowers are many ſet together, ſmall and yel ow, with longer ſpikes more like to Muſtard then Rocket, after which come longer and thicker cods about two inches long, ſmall and round not cloſing the ſtalke like the laſt, but ſpreading ſomewhat further off, wherein is ſmall yellow ſeede, nothing ſo ſharpe as the leaves: the roote is long and white, ſtronger and hotter then either leaves or ſeede and moſt neare unto Muſtard.

5. *Eryſimum anguſtifolium Neapolitanum.* Narrow leafed hedge Muſtard of *Naples.*

The lower leaves of this hedge Muſtard are long and narrow, ſomewhat hairy but ſoft, of a pale greene colour, cut in or torne on the edges, and pointed very like unto the common hedge Muſtard here firſt ſet downe, but thoſe that grow up higher upon the ſtalke, which is ſeldome more then one about a yard high and rough, are ſmaller and with fewer diviſions branched from the middle upwards, and ſometimes from the very bottome, bearing the ſmalleſt yellow flowers at the toppes of all the reſt, after which come ſmall long pods ſet on all ſides of the branches and ſtanding upright, thicke and blunt at the toppes with ſmall yellowiſh ſeede in them not very ſharpe.

6. *Eryſimo ſimilis hirſuta planta.* An hairy hedge Muſtard with uncut leaves.

This hairy hedge Muſtard-like plant hath many leaves lying on the ground cluſtering together, each whereof is rough, hairy, and whitiſh, an inch and a halfe long, unevenly dented about the edges, and ſome a little more deepely cut in, from whence riſe up ſometimes many ſtalkes, and ſometimes but one, rough, hairy and reddiſh at the bottome, with ſome few leſſer leaves ſet thereon compaſſing them at the bottomes: the flowers ſtand ſpike faſhion at the toppes of the ſtalkes, which are ſometimes branched made of foure ſmall white leaves, and after them riſe ſtraight long cods with ſmall ſeede in them.

The Place.

The firſt is very frequent in our Land by the wayes and hedge ſides and ſometimes in the open fields: the ſecond is more rare to meete with, yet is ſometimes found but ſtill in the better grounds which maketh it ſo large: the third is found wild in *Italy* as *Matthiolus* ſaith in the like places with the firſt: the fourth and fift are of *Naples* as *Columna* ſaith: the laſt groweth upon ſtones and rubbiſh, and upon old mudde walles at *Baſſil*, *Mompelier* and other places.

The Time.

Theſe doe flower ſometimes late and ſometimes earlier, but moſt uſually in *Iuly* or thereabouts.

The Names.

The Greeke name is ἐρύσιμον *Eryſimum* ἀπὸ τῦ ἐρέσθαι *a foliorum multiplici ſectione ſic dictum a quibuſdam putatur ab alijs* ἑρεπίμον *quaſi pretioſum*, neither of which ſeemeth ſo likely as ἀπὸ τῦ ἐρύδειν *quod ob ſuam caliditatem attrahendi facultate præditum eſt*: in Latine alſo *Eryſimum* and *Irio quod acrimonia ſua irruit in guſtum.* This is the *Eryſimum* of *Dioſcorides* and not of *Theophraſtus*, for hee placeth his *Eryſimum inter fruges* among the ſorts of Cornes or

Graynes

Graynes as ſhall be declared both when we come to ſpeak of them, & ſomewhat alſo in the Chapter of *Myagrium* following: *Galen* doth acknowledge both ſorts, for of this kind he ſpeaketh in 6. *ſimplicium medicamentorum*, and of the other in *primo de alimentorum facultatibus*: *Pliny* alſo ſpeaketh of them *Lib.* 18. *cap.* 7. and *lib.* 22. *cap.* 25. but in the end confoundeth them both together: for in the former place he ſaith *Eſtiva frumenta diximus Seſamum, Milium, Panicum*, and after *huic ſcilicet Seſamo ſimili eſt in Aſia Græciaque Eryſimum, idemq; erat niſi punguius eſſet, quod apud nos vocant Irionem, medicaminibus potius annumerandum quam frugibus.* And in the other place hee ſaith *Irionem inter fruges Seſamæ ſimilem eſſe diximus*, and *a Græcis Seſamum vocari: eſt autem fruticoſum folijs Erucæ anguſtioribus tamen, ſemine Naſturtij*, this being the deſcription of *Dioſcorides* his *Eryſimum* and the other of *Theophraſtus*. The firſt is called *Hierabotane fœmina* of *Brunfelſius*, *Verbena fœmina* and *Sinapi ſeptimum* of *Tragus*, *Sinapi alterum ſylveſtre* of *Fuchſius*, *Eryſimum Sinapi ſylveſtris ſpecies* of *Geſner in hortis*. *Irio* of *Matthiolus*, *Cordus in Dioſco. Lonicerus*, *Lugdunenſis* and *Cæſalpinus*, *Irio ſive Eryſimum* of *Lobel*: *Cleone Octavij Horatij* of *Anguilara*, and *Eryſimum vulgare* of *Bauhinus*: the ſecond is *Tabermontanus* his ſecond *Eryſimum* whoſe Figure *Gerard* hath placed for *Eruca ſativa*, *Bauhinus* calleth it *Eryſimum alterum Erucæ ſiliquis*: the third is the *Irio alter* of *Matthiolus*, *Lugdunenſis* and *Camerarius*, *Eryſimum verum* of *Anguilara*, *Dentillaria alia Irio aliquibus* of *Geſner in Hortis*, *Irionis tertia ſpecies* of *Cæſalpinus*, and *Saxifraga Romanorum* of *Lugdunenſis* according to his deſcription, but the figure is tranſpoſed to a contrary place under the other title of *Saxifragia aurea*, *Bauhinus* calleth it *Eryſimum polyceration vel corniculatum*, but is generally called by moſt *herbariſtes* with us *Eryſimum verum ſive montanum*: the fourth is called by *Columna Irio lævis Apulus Erucæ folijs*, and by *Bauhinus Eryſimum latifolium majus glabrum*, and was ſent him as he ſaith by the name of *Rapiſtrum Hiſpanicum non deſcriptum*, I have entituled it *Eryſimum latifolium Neapolitanum*: the fift is called by *Columna Rapiſtrum montanum Irionis folio*, but by *Bauhinus Eryſimum anguſtifolium majus*: but in this as in many other, *Bauhinus* doth much forget what he had written but two or three leaves before in his *Pinax*, for he ſetteth this for a *Rapiſtrum* among the other ſorts of *Rapiſtrum* but it cannot be an *Eryſimum* and a *Rapiſtrum* both, for ſo to doe were to make a confuſion unſufferable and too farre unfit ſo worthy a man as he was, or any other that would be accounted of any worth in his judgement. The laſt is called by *Bauhinus Eryſimo ſimilis hirſuta non laciniata alba*, and was called as he ſaith *Barbarea muralis* by his brother *Iohn Bauhinus*. The *Italians* call it *Eriſimo* and *Irione*, the *Spaniards Rinchaon*, the *French Velar* and *de la torteille*, the *Germans Hedericke* and *Wilder Senff*, the *Dutch Edel Rakette*, and in *Engliſh* by *Gerard* Banke Creſſes, but becauſe I finde the moſt judicious to make it a kind of wild Muſtard, I have thereupon entituled it wild Hedge Muſtard.

The Vertues.

The three firſt ſorts of *Eryſimum* as the moſt in uſe and effectuall doe temperately heate, conſiſting of a thinne ſubſtance, cutting and clenſing with ſome moyſt parts joyned therewith, whereby it doth not dry the thicke and viſcous flegme but maketh it eaſie to be ſpit forth, for it is ſingular good in all the diſeaſes of the Cheſt and Lungs, hoarſeneſſe of the voyce, and by the uſe of the decoction thereof for a little ſpace thoſe have beene recovered perfectly well, who had utterly loſt their voyce and therewith their ſpirits alſo almoſt: the juice thereof made into a Syrupe or Lohoc with hony or Sugar, is no leſſe effectuall for the ſaid purpoſe, and for all other coughes wheeſings and ſhortneſſe of breath: the ſame alſo is profitably taken of thoſe that have the Iaundies, the Pluriſie, paines in the backe and loynes, and for torments and wringings in the belly or in the Colon, which is called the Collicke being uſed alſo in Gliſters: the ſeede is held to bee a ſpeciall remedy againſt poyſon and venome. It is ſingular good for the paines in the hippes or huckle bones, called the hippe Goute or Sciatica, the Goute alſo and all joynt aches, as alſo for Fiſtulaes, hollow Vlcers, and eating or running Cankers, and for Apoſtums, ſores, and Cankers in the mouth or throate or behind the eares, and no leſſe alſo for the hardneſſe and ſwellings in womens breaſts or in the teſticles or ſtones.

CHAP. XII.

Thlaſpi. Treakle-Muſtard.

VNto the Creſſes, Rockets, and Muſtards perteine theſe herbes called *Thlaſpi*, Treakle-Muſtard as comming neareſt unto them both in forme and qualitie, whereof there are found at this day ſo many ſorts more then the former ages ever knew, that I muſt with theſe as I have done with many other ſuch herbes that yeeld a plentifull varietie, diſtribute them into ſundry rankes or orders, that ſo they may be both better deſcribed and apprehended.

Thlaſpi arvenſe. Treakle Muſtard of the Fields.

1. *Thlaſpi Drabæ folio.* Treakle Muſtard with broad flat Powches.

This kinde of *Thlaſpi* riſeth up with a hard round ſtalke about a foote high, parted into ſome branches, having divers ſoft greene leaves ſomewhat long and narrow ſet thereon, waved but not cut in on the edges, broadeſt towards the ends and ſomewhat round pointed: the flowers are white that grow at the toppes of the branches ſpike faſhion one above another, after which come large round powches, parted in the middle with a furrow, having one blackiſh browne ſeede in eyther ſide ſomewhat thicker and larger then in any other of the *Thlaſpies* that I know, ſomewhat ſharpe in taſte and ſmelling of Garlick, eſpecially in the fields where it is naturall, but in Gardens, neither ſo ſharpe nor ſmelling of Garlicke as others have expreſſed it, for any thing I could ever perceive by it my ſelfe: the rootes are ſmall and threddy periſhing every yeare.

2. *Thlaſpi Mithridaticum ſive vulgatiſſimum Vaccariæ folio.* Mithridate-Muſtard.

This *Thlaſpi* groweth higher then the former ſpreading more and longer branches, whoſe leaves are ſmaller and narrower ſometimes unevenly dented about the edges; the flowers are ſmall and white growing on long branches, with much ſmaller and rounder ſeede veſſells after them, and parted in the middle in the ſame manner with

1. *Thlaspi Drubæ folio.*
Treakle-Mustard with broad-flat powches.

2. *Thlaspi Vaccariæ folio.*
Mithridate-Mustard.

3. *Thlaspi majus.*
Great Treakle-Mustard.

6. *Thlaspi villosum capsulâ hirsutâ.*
Hairy Treakle-Mustard.

with ſmaller browne ſeedes therein then in the former, and much ſharper in taſte: the roote periſheth after ſeede time but abideth the firſt winter after the ſpringing.

3. *Thlaſpi majus.* Great Treakle-Muſtard.

The great Treakle-Muſtard hath larger, ſmoother and broader leaves then the laſt, ſomewhat pointed at the ends: the flowers are ſmall and white like the other, ſtanding at the toppes of the ſtalkes which are two or three foote high, with divers branches on them: the ſeede veſſells are round, and ſet with browne ſeene therein: the whole plant is of a ſtrong unpleaſant ſent and taſte.

4. *Thlaſpi Vaccariæ folio Monſpeliacum. French* Treakle-Muſtard.

The leaves hereof are ſomewhat like the leaves of the ſecond kind being ſmooth and of a darke greene colour, the flowers are ſmall and white alſo that grow on the ſtalkes which are about halfe a yard high: the ſeede veſſells are ſomewhat broad at the head like unto thoſe of Shephards-purſe but greater.

5. *Thlaſpi vaccariæ incano folio minus.* Small hoary *French* Treakle-Muſtard.

The creeping or bending branches of this *Thlaſpi* are all hoary over, ſcarſe riſing a handbreadth high, whoſe leaves are hoary alſo ſomewhat long and narrow without any footſtalke unto them but ſet thereon without order on each ſide, having ſmall white flowers on a ſhort ſpike and ſmall ſeede veſſells following.

6. *Thlaſpi villoſum capſulis hirſutis.* Hairy Treakle-Muſtard.

The ſtalke of this *Thlaſpi* is about a foote long round and hairy, at the bottome whereof grow divers hairy leaves ſomewhat long and broad ſet upon long footeſtalkes, but thoſe that are upon the ſtalke have no footeſtalke but compaſſe it at the bottome, being pointed at the ends and ſomewhat dented about the edges, the flowers ſtand at the toppe ſpike faſhion made of five white leaves a peece, after which ſucceede flat hairy powches parted as others are with reddiſh ſharpe ſeede within them.

7. *Thlaſpi arvenſe p rfoliatum majus.* The greater Treakle-Muſtard with Thoroughwax leaves.

The lower leaves hereof that lie upon the ground are ſmall and ſomewhat round like thoſe of *Baſſil*, but yet a little rent or torne on the edges at the bottomes, where they are ſmalleſt and a little dented about the other part, of a grayiſh greene colour, every one upon a ſmall footeſtalke, among which riſeth up a round ſtalke purpliſh at the bottome about a foote high ſometimes ſpotted, whereon grow ſingle leaves one above another at the joynts by certaine diſtances, which compaſſe it at the bottome in the manner of Thoroughwax leaves, and whereat likewiſe come forth other ſmaller leaves upon ſhort branches, whereon and at the toppes of the ſtalke ſtand divers ſmall white flowers that break forth out of reddiſh huskes, after which appeare ſmall flat powches like unto thoſe of Shepherds purſe parted in the middle, as is uſuall with moſt of the *Thlaſpies*, on each ſide whereof lye ſmall flat yellowiſh ſeede: the roote is long white and wooddy, the whole plant is more milde or leſſe ſharpe then others.

8. *Thlaſpi perfoliatum minus.* The ſmaller Treakle-Muſtard with Thoroughwax leaves.

This other *Thlaſpi* hath a few leaves lying on the ground, which are of a grayiſh greene colour, like both for

7. *Thlaſpi arvenſe perfoliatum majus.* The greater Treakle-Muſtard with Thoroughwax leaves.

8. *Thlaſpi perfoliatum minus.* The ſmaller Treakle-Muſtard with Thoroughwax leaves.

forme

9. *Thlaspi arvense minus luteum.*
Yellow field Treakle-mustard.

12. *Thlaspi incanum marinum Hispanicum, Eruca peregrina Clusii.*
Spanish hoary Treakle-Mustard.

formē and colour unto the leaves of *Brassica campestris* Codded Thoroughwax, but much lesser, those that grow up higher upon the stalke, which is scarse a foote high, and but a few set thereon are smaller, pointed at the ends, and broad at the bottomes compassing it like the last, the flowers are small and white and the seede vessells flat like the *Candy* kind, somewhat sharpe pointed.

9. *Thlaspi arvense minus luteum.* Yellow field Treakle-Mustard.

This hath sometimes but one stalke and at other times many set thicke with small long hoary and hard leaves, with a great long tuft of yellow flowers at the toppe, made of five leaves apeece, after which follow flat round yellowish powches, swelling in the middle, containing within them browne seede: the roote is small and long and dyeth every yeare.

10. *Thlaspi spanospermon Americanum.* The spare bearing *Thlaspi.*

This *Thlaspi* brancheth from the roote divers wayes somewhat thicke, set with long fat greene leaves somewhat like that of Mechlin: the toppes of the branches are without leaves, but stored infinitely with small yellowish flowers of foure leaves which endure onely one day, falling away for the most part without bearing fruit or seede or very sparingly, so that on the whole plant there will be scarse foure or five huskes of seeds gathered any yeare which are flat and a little long like to those of the manured Woade, with a sharpe tasted seede within, the root is hard with many fibres thereat, and tasteth sharpe like Cresses.

11. *Thlaspi incanum marinum Hispanicum, Eruca peregrina Clusio. Spanish* hoary Treakle-Mustard.

This small *Spanish* (or *Italian*) plant sendeth forth sundry slender round hoary stalkes about two foote high with many long and narrow leaves at the bottome, a little unevenly waved about the edges, narrowest at the bottome and broader to the ends, of a grayish greene colour or rather hoary, with a great ribbe in the middle of a sharpe taste, the upper leaves on the stalkes being smaller then the lower, with some pale yellow small flowers at the toppes, made of foure leaves a peece dented in the middle, after which succeede somewhat round and full seede vessells parted in the middle as many other sorts of *Thlaspi* are, with a small point at the end, containing therein many browne reddish flat shining sharpe seede: the roote is white and somewhat long, thick at the toppe with many fibres downewards.

The Place.

Divers of these sorts of Mustard have beene found in sundry places of our owne Land, especially the first and second, as halfe a mile from *Hatfield* by the river side under an hedge as you travell to *Hatfield*, and in the streete of *Peckam* on *Surrey* side, &c. the other sorts grow some in *Germany*, some at *Mompelier*.

The Time.

They flower and seede some earlier and later then others, even from *May* unto *August*.

The Names.

The Græcians call it Θλάσπι and Θλάσπη *Thlaspi* and *Thlaspe, quod fructus quasi infractus*, and also Θλάσπιδιον *Thlaspidion*

ſpidion quaſi fructum clypeatum and *ἄγριον ἄγειον Sinapi agreſte quod Sinapi acrimonia refert* : the *Latines* keepe the *Greeke* name for the moſt part and call it *Thlaſpi*, yet ſome do call it *Capſella* and *Scandulaceum*, *Naſturtium tectorũ* and *Sinapi ruſticum*: the *Italians* call it *Thlaſpi*: the *French Seneve Savage*: the *Germans* wilde *Kerſe*; the *Dutch Boerens Kerſe*; and we in *Engliſh* Treakle-Muſtard, or Mithridate-Muſtard, becauſe the ſecond ſort, eſpecially above any other is that *Thlaſpi* that the beſt do allow for the trueſt *Thlaſpi* to be uſed in Treakle and Mithridate. The firſt is called by *Lobel Thlaſpi Dioſcoridis Drabæ* and *Chamæline folio*, & *Scorodo-Thlaſpi* by *Dodonæus* and *Lugdunenſis*; and is the ſecond *Thlaſpi* of *Matthiolus*, called *Platycarpon* by *Camerarius*, and by *Bauhinus Thlaſpi arvenſe ſiliquis latis*: the ſecond *Lobel* calleth *Thlaſpi vulgatiſſimum Vaccariæ folio*, whoſe figure is the ſame with the firſt of *Matthiolus*, and differeth much from that which *Bauhinus* ſetteth forth in his *Matthiolus* by the name of *Thlaſpi vulgatum*: *Camerarius* calleth it *Thlaſpi verum cujus ſemine utimur in Theriaca*: by *Cordus in hiſtoria Thlaſpi Cardamoides*, by *Tragus Thlaſpi*, and *vulgare Thlaſpidion*, and by *Bauhinus Thlaſpi arvenſe incano folio majus* : the third is the *Thlaſpi majus* of *Tabermontanus* and *Gerard*, which *Bauhinus* firſt ſetteth forth by the name of *Thlaſpi arvenſe Vaccariæ lato læviq; folio*, but afterwards in his *Errata* appointed it to be amended & made *Acetoſæfolio* in ſtead thereof: the fourth is called by *Bauhinus Thlaſpi Vaccariæ folio burſæ paſtoris ſiliquis* : the fift is alſo called by him *Thlaſpi Vaccariæ incano folio minus*: the ſixt is alſo called by him *Thlaſpi villoſũ capſulis hirſutis*: the ſeventh is called by *Lugduinenſis Thlaſpi primum Dalechampij*, by *Tabermontanus Thlaſpi oleraceũ*, becauſe it is almoſt without taſte, by *Bauhinus Thlaſpi arvenſe perfoliatum majus*, who quoteth it to be *Columna* his *Thlaſpi alterum minus rotundifolium burſæ paſtoris fructu*; and yet *Columna* in his diſcription thereof maketh no mention of perfoliating in the leaves, *Gerard* alſo hath miſtaken this in calling it *Thlaſpi incanum* which belongeth to *incanum Mechlinienſe*: the eight is called by *Cluſius Thlaſpi pumilum*, and *Thlapi montanum minus*, but by *Bauhinus Thlaſpi perfoliatum minus* : the ninth is called *Alyſſum* by *Matthiolus*, and *Anguilara*, & *Alyſſum Matthioli* by *Lugdunenſis* and *Camerarius*, by *Lobel Thlaſpi Græcum* : by *Lugdunenſis Alyſſum minus Dalechampij* ; by *Tabermontanus Thlaſpi minus clypeatum*, by *Beſlerus in horto Eyſtetenſi Polium Alpinum flore luteo*, *Bauhinus* maketh two ſorts thereof calling them *Thlaſpi Alexandrinum campeſtre majus* & *minus*, and yet ſaith they are ſo like that they may be both accounted one ſort. You ſee I have referred it rather to the *Thlaſpi* than any other as neareſt reſembling it, and to this ranke of field *Thlaſpi* which is the proper place of the growing : the tenth is ſo called by *Cornutus* in his hiſtory of *Canada* plants : the laſt is called by *Cluſius Eruca peregrina*, and ſo doth *Lugdunenſis*, but *Lobel* inverteth the name calling it *Leucoium marinum Patavinum*, but *Cluſius* miſliking it, holdeth ſtill his owne, and *Bauhinus* more enclining to *Lobel* than him (for his loves ſake to *Padoa* as it ſeemes) calleth it *Leucoium incanum utriculo rotundo* : but becauſe both herbe and ſeede is hot and ſharpe, and ſo are not the *Leucoia* generally, I have thought it more fit to joyne it to the *Thlaſpies*.

The Vertues.

The moſt of theſe ſorts of Muſtards are hot and drie in the fourth degree, or very neare like unto Creſſes, for they are ſharpe and quicke in taſte, and are heating, rarefying, attracting and purging: It is ſet downe by ſome authors to purge the body both upward and downewards, and that if any exceede a due propor tion it will ſcoure unto bloud, but how truly I know not in that I never heard of any to make triall thereof in that manner: it is ſaid to procure womens courſes ſo forcibly that it ſuffocateth the birth: being taken inwardly it breaketh inward apoſtums and uſed in gliſters helpeth the *Sciatica*, the ſeede applied outwardly doth the ſame. It is an eſpeciall ingredient into *Mithridatum* and Treakle, for it is held to be of it ſelfe an antidote reſiſting poyſon, venome and putrefaction beſides the acrimony it addeth to the compoſition. It is alſo availeable in many of thoſe cauſes that Muſtard is uſed but ſomewhat weaker.

CHAP. XIII.

Thlaſpi Umbellatum. Vmbelliferous Treakle-Muſtard.

AN other kind of Treakle-Muſtard beare their flowers in tufts and round umbells, and not in ſpikes; of ſome whereof I have ſpoken in my former booke, that is, the *Thlaſpi Candiæ*, *Candy* tufts, both with white and purpliſh flowers, as alſo a *Spaniſh* kinde not ſet forth by any before.

1. *Thlaſpi Creticum album umbellatum majus*. Great white *Candy* Muſtard.

This *Candian* plant hath divers hard and ſmall ſtalkes, bearing a few long and narrow pointed ſmooth leaves, ſet on them one above another up to the toppes, where the white flowers grow in broad round tufts, ſomewhat larger than in that ſort is expreſſed in my former booke : the ſeede veſſels that follow are greater alſo with a pointell in the middle of them : the roote is ſmall and threddy, and endureth divers yeares not dying as the other doth.

2. *Thlaſpi umbellatum arvenſe Iberidis folio*. Variable flowred Muſtard.

The leaves hereof are ſomewhat long and narrow, cut in or deepely dented about the edges, more than thoſe of *Candy* Muſtard : the flowers grow in tufts or umbells like thereunto but of mixed colours, that is white and purple uſually, and ſometimes wholly white, and in others yellowiſh but much more rare : the ſeede is like the *Candie* kinde.

3. *Thlaſpi umbellatum Creticum flore albo odorato* Sweete Treakle Muſtard with a white flower.

This white *Candy* Muſtard is ſmaller, and groweth lower than the firſt, buſhing thicke with ſmaller and narrower leaves dented onely at the ends ; the flowers are white but ſmaller than they, and ſmelling very ſweete, after which follow ſuch like powches with yellowiſh ſeede in them : the roote periſheth yearely.

4. *Thlaſpi umbellatum Naſturtij folio Monſpeliacum*. *Mompeliers* umbilleferous Muſtard.

The ſtalkes of this Muſtard are many and greater than in the other before, bearing many more jagged leaves on them reſembling thoſe of the common garden Creſſes : the flowers are white in ſpikie rundles or umbells at the toppes which give ſmaller ſeede than the others but as ſharpe as any of them.

The Place.

Some of theſe grow about *Mompelier*, and the greater number in *Candy*, and but in gardens with us.

1. *Thlaſpi Creticum album umbellatum majus.*
Great white *Candy* Muſtard.

2. *Thlaſpi umbellatum arvenſe Iberidis folio.*
Variable flowred Muſtard.

3. *Thlaſpi umbellatum Creticum flore albo odorato.*
Sweete Treakle-Muſtard with a white flower.

4. *Thlaſpi umbellatum Naſturtij folio Monſpel.*
Mompeliers umbilliferous Muſtard.

The Time.

They flower and ſeede about the ſame time that the *Candy* kindes doē, expreſſed in my former booke, which is uſually not untill *Iuly*.

The Names.

The firſt *Bauhinus* calleth *Thlaſpi Creticum flore albo majus*, and I thinke it to be the *Thlaſpi Narbonenſe Centunculifolio* of *Lobel*, which as he ſaith the *Italians* and *Matthiolus* accounted an *Alyſſum*: the ſecond is taken to be the *Thlaſpi Allobrogicum* of *Cluſius*; and the *Thlaſpidij aliud genus vel tertium Tragi*, the *Thlaſpi amarum* of *Tabermontanus* and the *Naſturtium ſylveſtre* of *Lugduneuſis*, which *Bauhinus* entituleth *Thlaſpi umbellatum arvenſe Iberidis folio*, as I doe: the third is the fourth *Thlaſpi* of *Cluſius* called *parvum odorato flore*, which *Bauhinus* calleth *Thlaſpi umbellatum Creticum flore albo odoro minus*: the laſt is called by *Lobel Thlaſpi alterum minus umbellatum Naſturtij hortenſis folio Narbonenſe*, which *Lugdunenſis* and *Tabermontanus* doe both remember, the one by the name of *Thlaſpi aliud umbellatum Penæ*, and the other by the name of *Thlaſpi Narbonenſe umbellatum*.

The Vertues.

The vertues of theſe herbes are to be referred to the former, for being almoſt as ſharpe they cannot but worke the like effects, yet in a weaker manner, and therefore thus much ſhall be ſufficient for them.

CHAP. XIIII.

Thlaſpi Montanum. Mountaine Treakle-Muſtard.

THe next kinde of Treakle-Muſtards that are to be ſpoken of, are thoſe that grow upon high hills and mountaines and in rockie ſtonie places.

1. *Thlaſpi montanum Glaſtifolio majus*: *Cluſius* his *Hungarian* Treakle-Muſtard.

This *Thlaſpi* riſeth up with divers ſmall but ſtrong ſtalkes a foote or more high, ſet at diſtances with long and ſomewhat broad leaves, compaſſing it at the bottome as the *Braſica campeſtris* doth, and neare unto the ſame colour, greene above and grayiſh underneath ſmelling ſomewhat like onto Garlike, as thoſe alſo doe that lie upon the ground: the flowers are many and white plentifully growing at the toppes without any ſent, which afterwards give hard and flat powches, not parted as others are, but whole and round ſticking forth in the middle like a buckler, in the middle whereof lieth but one ſeede, the roote is buſhie and full of ſtrings and fibres that contiune many yeares.

1. *Thlaſpi montanum Glaſtifolio majus.* *Cluſius* his firſt *Hungarian* Treakle-Muſtard.

2. *Thlaſpi montanum Glaſti folio minus.*

The ſmall Treakle-Muſtard of *Baden*.

This hath a great many ſmall leaves lying on the ground round about the roote, very like unto the blew Dayſie, full of juyce, and of a darke blewiſh greene colour, among which riſe up divers ſtalkes about a foote high, bearing thereon many leaves longer and more pointed than the lower, and at the toppes ſundry white flowers one above another, which afterwards bring flat powches like thoſe of Shepheards purſe: the roote is long white and fibrous.

3. *Thlaſpi montanum ſemper virens*:

Evergreene Mountaine Muſtard.

The ſtalke of this *Thlaſpi* is ſomewhat great and wooddy, covered from the roote upwards to the branches, with a browniſh rugged barke ſet with divers long white leaves at ſpaces, ſomewhat like to thoſe of Stocke-Gillowflowers but ſmaller and very quicke and ſharpe in taſte: at the toppes of the branches which are many and much diſperſed ſtand tufts of white flowers, after which come ſuch like husks as are in the common *Thlaſpi*, and ſuch like ſeede in them very hot and ſharpe: the roote ſpreadeth it ſelfe into many branches and periſheth not, but abideth with the ſtemme alſo above ground uncorrupted many yeares.

4. *Thlaſpi ſaxatile rotundifolium.*

Mountaine Treakle-Muſtard with round leaves.

This mountaine *Thlaſpi* hath riſing from a ſmall long yellowiſh roote many ſmall weake bending ſtalkes a foote high, ſhooting forth fibres at the joynts as they lie next the ground, where the leaves grow ſmall and ſomewhat round, from the upper joynts ſpring forth ſmall naked branches an hand breadth long, bearing a few pale coloured flowers, and after them ſmall pods upon very ſlender foot ſtalkes, wherein is contained very ſmall ſeede.

5. *Thlaſpi Alpinum minus capitulo rotundo.* Small mountaine Muſtard with round heads.

This ſmall mountaine *Thlaſpi* hath from among many ſmall ſhort leaves, that grow next the ground being pointed at the ends, lightly dented about the edges, and every one on a ſhort foote ſtalke, divers tender ſtalkes riſing up about a foote high, branched at the toppes, and bearing a few narrow long leaves on them, and ſmall white flowers above them, after which follow ſmall round ſeede veſſells divided by a ſmall skinne into two parts, ſtanding upon very ſlender foote ſtalkes with ſmall yellowiſh ſharpe ſeede within them: the roote groweth ſomewhat great at the toppe and ſmaller downewards.

2 *Thlaspi montanum Glastifolio minus.*
The ſmaller Treakle-Muſtard of *Baden.*

3. *Thlaspi montanum ſemper virens.*
Evergreene mountaine Muſtard.

5. *Thlaspi Alpinum minus capituto rotundo.*
Small mountaine Muſtard with round heads.

11. *Thlaspi montanum luteum majus.*
The greater yellow *Thlaspi.*

13. *Thlaſpi Veronicæ folio.*
Treakle Muſtard with Speedewell leaves.

14. 15. *Thlaſpi montanum Vermiculato acuto folio: & alterum carnoſo rotundo folio.*
Treakle Muſtard with very ſmall and pointed leaves; and another with ſmall thicke leaves.

6. Thlaſpi Alpinum majus capitulo rotundo. The greater mountaine Muſtard with round heades.

The greater kinde hath divers heads or tufts of ſomewhat longer leaves next the ground, from the middle of each whereof riſeth up a bigger ſtalke, ſet with narrow leaves up to the toppes, where they branch forth and beare ſuch like white flowers and round heades with ſeede, as the leſſer kinde doth but larger: the roote likewiſe is ſomewhat great.

7. Thlaſpi Alpinum repens. Creeping mountaine Treakle Muſtard.

This ſmall *Thlaſpi* hath many ſmall branches creeping by the ground of foure or five inches long with ſome few leaves that are ſomewhat round ſet without order on them, and at the toppes many white flowers ſomewhat large and great, in whoſe places afterwards come ſmall flat powches, containing ſeede in taſte like unto Rocket: the roote is ſmall and long.

8. Thlaſpi parvum ſaxatile flore rubente. Small reddiſh flowred Treakle-Muſtard.

The roote of this *Thlaſpi* is white and long, from whence come three or foure round upright yet weake ſtalkes, with very ſmall thicke and round leaves at the bottome, not much broader than the fruit or ſeede veſſells themſelves, of a pale greene colour, and thoſe that grow up higher ſmaller and narrower up to the toppes, where the flowers made of foure leaves apeece, ſtand in tufts many ſet together of a pale reddiſh or bluſh colour, ſtriped with veines of a deeper red riſing out of reddiſh greene huskes being the outer flowers, which as a crowne compaſſe the tufts, for from the middle riſe other flowers afterwards upon long foote ſtalkes, and flat ſeede-veſſels after they are paſt with ſharpe ſeede in them, but the rootes and leaves are bitter.

9. Thlaſpi ſaxatile Polygalæ folio. Mountaine *Thlaſpi* with Lentill-like leaves.

The ſtalkes of this *Thlaſpi* riſe to be about a foote high having ſmall leaves on them, in forme like unto *Polygala* or Milkeworte, but much ſmaller or rather like unto thoſe of the pulſe we call Lentills (and in ſome countries Tilles) that is ſomewhat longer than round: the flowers are many ſmall and white perking on the toppes of the ſtalkes, which afterwards give ſmall round ſeede veſſells, parted in the middle with very ſmall ſeede therein.

10. Thlaſpi montanum luteum majus. The greater yellow *Thlaſpi*.

From a ſmall long roote ſpring forth ſundry weake branches ſcarce able to ſtand upright, ſet with divers ſmall long and ſomewhat narrow leaves a little hoary without order, ſomewhat like unto *Serpillum* Mother of Time: at the toppes grow many ſmall yellow flowers ſet together in a tuft or umbell ſomething large, where afterward ſtand ſmall ſeede veſſells with very ſmall ſeede in them.

11. Thlaſpi montanum luteum minus. The leſſer yellow *Thlaſpi*.

The leaves of this *Thlaſpi* are ſmall ſomewhat long and narrow, pointed at the ends like unto the laſt, but ſmaller, rough and hoary withall, the ſtalkes are browne leaning downe to the ground rough and hoary likewiſe, bearing many flowers at the toppes of them ſomewhat larger than the laſt, and

of a deeper yellow colour almoſt like the Wall-flower, every leafe being round pointed, and cut in in the middle making them ſeeme like hartes which doe not ſtand in round tufts or umbells but in ſhort ſpikes, after which come rough and hoary round ſeede veſſels, with a pointell ſticking forth in the middle of every one of them, and containing one flat round yellowiſh ſeede in them: the roote is ſmall and long and ſpringeth new leaves and ſtalkes every yeare: this hath but little ſharpeneſſe in it.

12. *Thlaſpi Veronicæ folio.* Treakle-Muſtard with Speede-well leaves.

This *Thlaſpi* hath divers leaves lying next the ground rough or hairy and almoſt round, of the bigneſſe of the nayle of ones thumbe, and of a deepe greene colour every one upon a ſhort footeſtalke, ſomewhat reſembling the leaves of Speedewell: the ſtalke is hairy halfe a foote high branching uſually from the bottome, and ſometimes without branches, ſet with very few leaves that compaſſe them at the bottomes and bearing at the toppes many ſmall white flowers and after them ſmall round and long pods upon ſmall footeſtalkes one above another ſpike faſhion, containing in each a ſmall browniſh yellow ſeede ſomewhat ſharpe in taſte: the roote is white and long.

13. *Thlaſpi montanum vermiculato acuto folio.* Treakle-Muſtard with very ſmall and pointed leaves.

From a great white hard roote riſe ſundry thicke and ſhort riveld ſtalkes above a ſpan long, thicke ſet with very ſmall leaves without order, being narrow and almoſt round, & pointed at the ends, ſomewhat hairy about the edges and of a ſad greene colour, but ſmaller upwards unto the flowers at the toppes which grow many buſhing together in a large umbell, conſiſting of foure white or ſomewhat reddiſh leaves, the under couple being greater then the upper with ſome yellow threds in the middle: the ſeede followeth in broad round flat powches, hollowed in the middle like a Spoone on that ſide next the ſtalke and bunching or bellying forth on the outſide, flat alſo at the head, with a ſeame in the middle as is ſeene in many ſorts of theſe Thlaſpies which is flat and yellow in boththe ſides.

14. *Thlaſpi montanum carnoſo rotundo folio.* Treakle-Muſtard with ſmall thicke leaves.

The roote of this ſmall *Thlaſpi* is long, ſmooth, white and hard, from whence ſpring divers reddiſh ſtalkes, ſet thicke with ſmall leaves that are fleſhie, and not much broader then the powches with ſeede, of a blewiſh greene colour, yet ſmaller and narrower up to the toppes, where the flowers ſtand in a ſmall round tuft of a bluſh colour ſtriped with reddiſh lines or ſtrakes: after which come ſmaller flat pouches a little dented at the toppes and purpliſh with ſmall ſeede in them like the other but leſſe.

The Place.

All theſe Muſtards grow on hills and in rocky ſtony places in ſeverall Countries, yet ſome of them are found in our owne Land in the like ſtony places.

The Time.

They all for the moſt part flower and give their ſeede in the Sommer moneths, yet ſome ſooner or neare the Spring.

The Names.

The firſt of theſe is called by *Lobel*, *Camerarius*, and *Tabermontanus Thlaſpi Pannonicum Cluſii*, by *Cluſius* himſelfe *Thlaſpi primum vel montanum peltatum*, and by *Bauhinus Thlaſpi montanum Glaſti folio majus*: the ſecond is the ſecond *Thlaſpi montanum* of *Cluſius*, called alſo by him *Thlaſpi Badenſe*, by *Lobel* and *Tabermontanus Thlaſpi album ſupinum*, *Columna* mentioneth it under the title of *Thlaſpi montanum primum burſæ paſtoris fructu*, which *Bauhinus* calleth *Thlaſpi Alpinum Glaſti folio minus* according to his correction in his Appendix: the third is *Lugdunenſis* his *Thlaſpi montanum candidum*, and called by *Bauhinus Thlaſpi montanum ſemper virens*: the fourth *Bauhinus* onely maketh mention of by the name of *Thlaſpi ſaxatile rotundifolium*: the fift is called by *Camerarius* in his Epitome upon *Matthiolus* and *in horto*, *Thlaſpi tertium ſaxatile*, and by *Bauhinus* in his *Matthiolus Thlaſpi ſaxatile minore folio*, but in his *Pinax* and *Prodromus*, *Thlaſpi Alpinum minus capitulo rotundo*, and by *Pona* in his deſcription of Mount *Baldus Thlaſpi petræum Myagroides*: the ſixt is the third *Thlaſpi ſaxatile* of *Matthiolus*, which *Lugdunenſis* and *Thalius* doe alſo mention, but *Thalius* his deſcription thereof is much differing from it, and *Camerarius* upon *Matthiolus* ſaith hee never found that ſort among rockes and ſtony places, but in the fields and under hedges, and therefore in his *Matthiolus* he ſetteth forth that figure of that which grew with them, and omitted the other of *Matthiolus*, *Bauhinus* afterwards ſaith that ſuch an one as *Matthiolus* ſet forth was brought him out of *Italy* and therefore he giveth the figures of them both in his *Matthiolus* and *Prodromus* by the title of *Thlaſpi Alpinum majus & minus capitulo rotundo*, the ſeaventh is called by *Bauhinus* onely *Thlaſpi Alpinum repens*: the eighth is the *Lithothlaſpi quartum carnoſofolio* of *Columna* and called by *Bauhinus Thlaſpi parvum ſaxatile flore rubente*: the ninth is called by *Bauhinus Thlaſpi ſaxatile Polygalæfolio* according to the correction in his *Appendix*, folio 519. at the latter end of his *Pinax*, but is among his *Thlaſpies* folio 107. *Vermiculato folio*: the tenth is *Lobel* his *Thlaſpi ſupinum luteum* which *Bauhinus* entituleth *Thlaſpi montanum incanum luteum Serpillifolio majus*, as hee doth the eleventh *Thlaſpi ſaxatile incanum luteum Serpillifolio minus*, and is the *Ionthlaſpi luteo flore incanum montanum διοσκοεῖδης* of *Columna*: the twelfth is called by the learned of *Mompelier*, *Thlaſpi Veronicæ folio*, and as *Bauhinus* ſaith is the *Draba minima muralis Dioſcoridis* of *Columna*, and yet hee maketh it to be a *Burſa paſtoris* alſo, calling it *major loculo oblongo*, but *Columna* ſaith it hath a ſharpe taſte like a *Draba* but ſo hath not *Burſa paſtoris*: the thirteenth and the laſt are mentioned by *Columna* under the ſame titles here expreſſed.

The Vertues.

Theſe ſorts of *Thlaſpi* alſo as they are all or the moſt of them of the like ſharpeneſſe in taſte unto the former, ſo they may bee of the ſame qualities in operation but no ſpeciall properties being ſet downe by any author that have made mention of them nor other private experience, I cannot ſpeake further concerning any of them.

CHAP.

CHAP. XV.

Thlaſpi clypeatum. Buckler-like *Thlaſpi* or Treakle-Muſtard.

A Fourth kind of *Thlaſpi* is to be ſpoken of, whoſe difference from others conſiſteth chiefly in the ſeede veſſells which are formed ſomewhat like a buckler, and thereof taketh the name, of which we have not many to entreat, but as they are they ſhall here follow.

1. *Thlaſpi clypeatum Hieracifolium majus.* The great Buckler-Muſtard.

This *Thlaſpi* hath divers long leaves lying next to the ground, ſomewhat like unto thoſe of common Hawkeweede, but leſſer and unevenly dented or rather waved about the edges, and a little hairy alſo, among which riſe up two or three weake trayling ſtalkes, with a few leaves thereon much ſmaller then thoſe below, without any dent or inciſion in them at all, at the toppes they ſpread a few branches, whereon are ſet many pale yellow flowers made of foure leaves a peece, which afterwards give flat round powches divided as it were into two round parts like bucklers, the footeſtalke ſtanding betweene them, and ending in a ſmall pointell, in each ſide whereof is conteined one ſeede of little or no ſharpe taſte at all: the roote is ſmall and ſlender periſhing every yeare.

2. *Thlaſpi clypeatum aſperum minus.* The leſſer Buckler-Muſtard.

This other or leſſer Buckler-Muſtard hath leſſer leaves but more rough and hairy then the former, deepely dented about the edges, and from them riſeth a ſmall weake ſtalke, divided at the toppe into two or three branches, ſet with narrow leaves and ſmall yellowiſh flowers, made of five leaves a peece at the toppes one above another ſpike faſhion, where afterwards ſtand ſmall Buckler-like heads, and pointed in the ſame manner as are in the former but ſmaller as the ſeede is alſo: the roote is ſmall and periſheth.

3. *Thlaſpi biſcutatum villoſum flore calcari donato.* Spurre flowred Buckler *Thlaſpi.*

The leaves of this *Thlaſpi* that lye on the ground next the rooteare about two inches long & halfe an inch broad, cut in on the edges into deepe gaſhes being hairy and of a light hoary greene colour: the ſtalke is likewiſe hoary and hairy of a cubit high, ſet with ſuch like torne leaves but leſſer and compaſſing it about at the bottome branched at the toppe and bearing large pale yellow flowers conſiſting of foure leaves a peece, with a ſmall heele or ſpurre behind like unto thoſe of Todeflaxe, with a ſmall pointell and ſome threads about it in the middle ſtanding in rough huskes, after the flowers are paſt appeare ſuch like buckler-like ſeede veſſels as are in the former, parted into two ſides, with a pricke in the middle betweene them ſtanding forth: the roote is thicke and long of the bigneſſe of ones little finger of a taſte betweene ſweet and ſharpe, but the leaves and ſeede much more ſharpe and biting upon the tongue.

4. *Thlaſpi clypeatum minus Serpillifolio.* Small Buckler-Muſtard with wild Time leaves.

This is a very ſmall herbe not above foure or five inches high whoſe lower leaves are as ſmall as thoſe of Mother of Time, of a whitiſh yellow greene colour, thoſe on the ſtalkes are like the other but ſmaller, and thickly

1. *Thlaſpi clypeatum Hieracifolium majus.*
The greater Buckler-muſtard.

5. *Thlaſpi clypeatum arboreſcens Creticum.*
The great Buckler-muſtard of *Candy.*

ſet thereon, the flowers are ſmall and yellow like the laſt, and ſo are the ſeede veſſells but cleare and tranſparent like cleare Parchment ſomewhat yellowiſh: the taſte whereof is ſmall like the firſt.

5. *Thlaſpi clypeatum arboreſcens Creticum.* The great Buckler-*Thlaſpi* of *Candy*.

This hath the flower part of the ſtalke thicke and ſhort and wooddy, the branches riſing from thence are of a cubits length and wooddy alſo, with two hoary thicke leaves ſet all along the branches, many of them turning one way, bearing at the toppes ſundry ſmall white flowers, and after them round flat huskes, reſembling old faſhioned Bucklers among the *Venetians*, with ſmall round flat ſeede within them, and ſomewhat ſharpe: the roote is thicke, ſhort and wooddy, with divers ſtrings and fibres thereto.

The Place.

Some of theſe ſorts are naturally growing about *Mompelier* and the parts not farre off, ſome alſo about *Naples* as *Columna* relateth, and the laſt in *Candy* as *Alpinus* ſaith.

The Time.

They flower and give their ſeede about the ſame time that the others before ſet downe doe, or ſomewhat later.

The Names.

The firſt is called by *Lobel Thlaſpi parvum Hieracifolium ſive Lunaria lutea Monſpelienſium*, by *Cluſius Thlaſpi clypentam*, by *Camerarius Thlaſpi biſentotam vel lunaria biſulcata*, by *Lugdunenſis Lunaria lutea Dalechampij*, by *Thalius Leucoium montanum primum*, by *Columna Leucoium Alyſſoides umbellatum montanum*, by *Tabermontanus Thlaſpi clypeatum minus*, but in *Gerard* the figure is miſſet, the greater inſtead of the leſſer as the deſcriptions declare, and by *Bauhinus Thlaſpi biſentotum aſperum Hieracifolium majus*: the ſecond *Columna* calleth *Iondrabæ Alyſſoides Apulaſpicata* and by *Bauhinus Thlaſpi viſcutatum aſperum minus*: the third *Columna* calleth *Leucoium montanum flore pedato* referring it rather to *Leucoium* then to a *Thlaſpi* although the ſeede veſſells are farre differing, but *Bauhinus* contrariwiſe maketh it a *Thlaſpi* as it doth moſt fitly thereunto agree, and calleth it *Thlaſpi biſentotum villoſum flore caloari donato*: the fourth is called by *Lobel Thlaſpi alterum minus Clypeatum Serpillifolio*, by *Lugdunenſis Thlaſpi minus clypeatum Penæ*, by *Columna Thlaſpi minimum ſpicatum lunatum*, by *Cæſalpinus Lunaria Græca quarta*, and by *Bauhinus Thlaſpi clypeatum Serpillifoliom*: the laſt is ſo named by *Alpinus* in his booke of exoticke plants as it is in the title.

The Vertues.

There is none of theſe herbes of halfe that fierceneſſe or ſharpeneſſe that many of the others before are, neyther is any of them uſed in Phyſicke that I know for any purpoſe, but ſerve onely as varieties in nature to pleaſe the curious.

CHAP. XVI.

Thlaſpi fruticoſum. Shrubby, buſhie, or wooddy Treakle-Muſtard.

A Fift kind of *Thlaſpi* is of thoſe that grow greater then the reſt and more wooddy like a ſmall buſh, whereof there are ſome varieties here to be expreſſed.

1. *Thlaſpi fruticoſum Leucoij folio latifolium.* The broader leafed Treakle-Muſtard.

This broad leafed wooddy *Thlaſpi* riſeth up with a wooddy round ſtalke halfe a yard high bearing thereon long pale greene leaves like unto thoſe of the Stock-Gilloflower but ſhorter, and narrower the flowers that ſtand at the toppe are ſomewhat large and of a pale whitiſh yellow colour, after which follow ſeede veſſells made like ſhields parted into two parts, as many other of the former ſorts are.

2. *Thlaſpi fruticoſum Leucoij folio anguſtifolium.* Narrow leafed wooddy Treakle-Muſtard.

This other wooddy *Thlaſpi* ſpreadeth with many branches thicke ſet with narrow long leaves, very like unto the ſmall Sea *Thlaſpi*: the flowers at the toppe are white ſtanding many together in ſhort ſpikes, which turne into ſmall flat ſeede veſſells like unto the reſt: the roote is white long and wooddy ſpreading much under ground.

3. *Thlaſpi fruticoſum Hiſpanicum. Spaniſh* wooddy Treakle-Muſtard.

This *Thlaſpi* ſhooteth forth many weake hard and wooddy ſtalkes, ſcaſe able to ſtand upright, thicke ſet on all ſides with rough hairy leaves like unto Savory up to the toppe where grow many ſmall white flowers in ſhort ſpikes and after them ſmall flat powches with ſeede in them: the roote is hard and wooddy periſhing every yeare.

4. *Thlaſpi fruticoſum ſpinoſum.* Thorny Treakle-Muſtard.

This thorny *Thlaſpi* riſeth up with divers hard wooddy ſtalkes branching forth diverſly ſet in divers places with ſhort and ſharpe thornes, the leaves are diſperſed on the branches without any order, at ſome places one or two together and at others more which are ſmall and long, pointed at the ends, and hoary as it were all over eſpecially on the underſide: the flowers are white ſtanding thicke together at the firſt, but afterwards grow into long ſpikes where come ſmall ſeede veſſells like unto the ſmaller ſorts of *Thlaſpi*: the roote ſpreadeth divers wayes, yet abideth not but periſhing as the reſt doe.

5. *Thlaſpi incanum Machlinienſe.* Hoary Thlaſpi of *Machlin*.

This Thlaſpi of *Machlin* groweth firſt with many long and whitiſh hoary leaves lying on the ground, and afterwards buſhing thicke upon the ſlender weake ſtalkes bearing a number of ſmall white flowers at the toppes in tufts and afterwards ſpread more in length, where follow ſmall round ſeede veſſells a little pointed at the ends containing ſmall ſeede therein, and leſſe ſharpe then any others: the roote is long and white periſhing after ſeede time every yeare, but rayſing it ſelfe againe of the ſhed ſeede. Sometimes I have ſeene this kind to give double flowers but no ſeede neither did it endure long after in my Garden.

6. *Thlaſpi fruticoſum parvum Oſiridis folio.* Small buſhie Thlaſpi with ſmall narrow leaves.

This ſmall buſhie Thlaſpi ſhooteth forth ſundry ſmall hard ſtalkes, branched out towards the toppes with many ſmall narrow leaves on them, and plentifully ſtored with long ſpikes of white flowers and ſometimes with yellow

1. *Thlaspi fruticosum folio Leucoij angustifolium.*
Narrow leafed wooddy Treakle-mustard.

3. *Thlaspi fruticosum Hispanicum.*
Spanish wooddy Treakle-mustard.

4. *Thlaspi spinosum fruticosum.*
Thorny Treakle-mustard.

5. *Thlaspi incanum Mechlinienses.*
Hoary Thlaspi of *Mechlin.*

yellow, after which follow ſmaller ſeede veſſells than in theſe of the Mithridate *Thlaſpi*, and ſmaller browne ſeede in them and very ſharpe in taſte: the roote is ſmall, long, and ſtringie.

The Place.

Theſe ſorts grow in ſeverall countries, ſome in *France* about *Marſelles* and *Mompelier*, ſome in *Spaine* and *Italy*, and ſome in the *Low Countries*, the ſame alſo that were thought proper to ſome countries have beene found alſo in others.

The Time.

They all flower in Summer, and give their ripe ſeede ſhortly after, but few of them abiding after the ſeede is ripe.

The Names.

The firſt is called by *Bauhinus Thlaſpi fruticoſum Leucoij folio latifolium*, as it is in the title: the ſecond is called by *Lobel* in his Obſervations *Thlaſpi fruticoſum folio Lencoij marini minoris*, whom *Lugdunenſis* and *Tabermontanus* doe follow, but *Bauhinus* calleth it *Thlaſpi Leucoij folio anguſtifolium*; and *Camerarius Thlaſpi ſempervirens biflorum*: the third is called by *Lobel Thlaſpi fruticoſum alterum*, and ſo doe *Lugdunenſis* and *Tabermontanus*; and as *Cluſius* thinketh is his *Thlaſpi ſextum Hiſpanicum albo flore*, by *Bauhinus Thlaſpi fruticoſum folio Thymbræ hirſuto*: the fourth is called by *Lobel* and other ſince him *Thlaſpi fruticoſum ſpinoſum Narbonenſe* or *Thlaſpi ſpinoſum*: the fift is called by *Lobel* and *Cluſius Thlaſpi incanum Mechlinienſe*, by *Bauhinus Thlaſpi fruticoſum incanum*, who taketh it to be *Thlaſpi incanum fruticoſum Franconiæ* of *Camerarius in horto*, as alſo the *Iberis* of *Tabermontanus* which *Gerard* hath expreſſed under the title of *Thlaſpi fruticoſum*.

The Vertues.

Some of theſe ſorts as are ſharpe as any of the former which therefore may be judged as conduceable for the greefes the firſt ſorts were appropriate as they: the others that are little or nothing ſharpe are held to be unprofitable.

CHAP. XVII.

Thlaſpi exoticum. Strange faſhioned *Thlaſpi*.

THe laſt kinde of theſe Treakle-Muſtards are ſuch as are in forme of leaves, or growing farre differing from all the other kindes and not from the ſtrange countries where they grow.

1. *Thlaſpi hederaceum.* Ivie leafed Treakle-Muſtard.

This *Thlaſpi* ſhooteth up with many weake tender ſtalkes leaning downewards, and rather creeping upon the ground, than raiſing it ſelfe to be much above a ſpanne high, diſperſedly ſet with ſmall broad leaves, thicke and ſhort, broad at the bottome, cornered about the middle, and pointed at the end, ſomewhat reſembling Ivye leaves: the flowers are ſmall and white growing ſpike faſhion at the toppes of the branches, which afterwards yeeld ſmall round ſeede veſſells parted at the ends containing ſmall ſeede and ſharpe, like *Thlaſpie*: the roote is ſmall, long and fibrous periſhing every yeare.

1. *Thlaſpi Hederaceum.*
Ivie leafed Treakle-Muſtard.

2 *Thlaſpi aliud Lunatis folijs ſive Lunaria Magorum Arabum Lobelij.*
Strange Moonewort-like Treakle Muſtard.

2. *Thlaſ-*

2. *Thlaspi aliud Lunarijs folijs sive Lunaria Magorũ Arabum Lobelio.* Strange Mooneworte-like Treakle-Mustard.

Although it be not determined by *Lobel* to what *genus* this plant is to be referred, yet I have presumed to place it next unto the Ivie leafed kind untill it can be otherwise disposed, his discription thereof being briefe thus. It shooteth forth in *March* from an ash coloured bending wooddy roote divers leaves somewhat like unto a *Lunaria*, or like unto the new sprung leaves of the *French* round leafed Sorrell, and almost like also to those of the Ivie leafed Treakle-Mustard, hee neither saw flowers nor fruit: he found this hee saith onely in *Savoy*, in the vallyes that are betweene that high hill called *Mons Seny*, and Saint *Iean de Morienne*.

3. *Thlaspi Alexandrinum. Levant Thlaspi* or of *Alexandria.*

This is a small plant but very beautifull, scarse halfe a foote high, from whose roote which is long and slender riseth vp divers branched stalkes, at each joint whereof where it brancheth groweth a large round leafe compassing the stalke on both sides, round like unto those of Thoroughwaxe, from the toppes of the branches come forth many flowers, and after them small round seede vessells ending in a point, parted in the middle by a skinne, in each whereof lie small seede.

The Time.

The first *Lobel* saith hee foundin *Portland* which is an Iland belonging to *Cornewall* nor farre from *Plimmouth* in the West of *England*, and in divers of the sea coastes thereabouts: the second he likewise found he saith in *Savoy* as it is set downe in the descripion: the last came from *Alexandria* and other parts of *Syria*.

The Place.

The first flowreth and seedeth plentifully both in the naturall places, and whether it is transplanted in the Summer moneths: but the second, as is said was not knowne: the last as comming out of an hotter climate is somewhat more tender and hard to be kept a Winter, for it beareth not the first yeare, and hardly the next but very late.

The Names.

The first is called by *Lobel Thlaspi hederaceum*, and so doth *Lugdunensis*, and others that have made mention thereof since; *Bauhinus* calleth it *Thlaspi repens hederæ folio*: the second is called by *Lobel Lunaria Magorum Arabus*, as he saith the *Italians* doe call it: *Bauhinus* calleth the last *Thlaspi Alexandrinum* being so called by *Cortusus* who sent the seede.

The Vertues.

There hath no triall beene made of any of these sorts by any that I know, and therefore thus much shall suffice to have spoken of both of those and the others before, for I intended not to invent receipts of those things I mention, but to relate what I have reade or knowne to be practised.

CHAP. XVIII.

Draba sive Arabis. Arabian Mustard.

ASneerest both in forme and qualitie unto the *Thlaspi* is this herbe *Draba* which I have Englished *Arabian* Mustard for want of a fitter name, for although the Latine or Greeke name (whether ye will, or neither if ye will) may seeme to urge an *Arabian* originall, yet we find that it is as an adulterate a Greek name as a Latine, and not thought to be of *Dioscorides* his owne setting downe, but intruded by others into some copies of his, because others that are more anthenticke have it not at all: the ancients have mentioned but one sort, but these later times have produced divers others, which have beene so called of the likenesse in some parts, unto the most knowne and common.

1. *Draba vulgaris.*

The more common or knowne *Arabian Mustard.*

This *Arabian* Mustard from a creeping white roote shooteth up in divers places many straight straked stalkes set about with grayish greene leaves, somewhat broad and not very long, a little pointed at the end, and broad at the bottome compassing them, but those that grow at the foote of them have every one a short foote stalke and dented unevenly about the edges: the toppes of the stalkes are spread into many branches, all of them rising to an equall height, with many small whiteflowers set thereon of foure leaves apeece, forming a large tuft or umbell, where after they are past stand small round seede vessells divided into two parts like some of the former *Thlaspies* with a small pointell at the end, containing in each part one seede somewhat sharpe as the leaves are a little also: this by the creeping rootes maintaineth it selfe in the Winter and perisheth not.

1. *Draba vulgaris.*
The more common or knowne *Arabian* Mustard.

2. *Draba minor capitulis orbicularibus.*

The smaller *Arabian* Mustard.

This smaller sort hath divers hairy leaves rising from the roote somewhat dented about the edges, and standing upon long foote stalkes, from among which spring up a small slender stalke about an hand breadth high, having a few leaves much longer and narrower set thereon, and from the middle thereof plentifully stored with small branches and round heads on them (for the flowers have

not

not beene obſerved) parted by a thinne skinne containing one ſeede in each part: the roote is reaſonable great for the ſmallneſſe of the plant, with ſmall fibres annexed thereunto and living many yeares.

3. *Draba tenuifolio.* Thinne leafed *Arabian* Muſtard.

From a ſmall long white roote riſe brittle ſhort ſtalkes about a foote long, with ſmall branches towards the toppes, ſet with a few pale greene leaves of two inches long and one broad, dented about the edges and compaſſing them at the bottome, of a fierie hot and ſharpe taſte: the flowers ſtand at the toppes as it were ſpike-faſhon, ſmall and white, which afterwards give ſmall round heads every one ſet upon a long foote ſtalke.

4. *Draba alba ſiliquoſa repens.* The more creeping codded *Arabian* Muſtard.

This more creeping ſquare codded *Arabian* Muſtard ſendeth forth many heads of leaves compaſſing one another circlewiſe, thicke full of juyce ſomewhat broad, dented about the edges and of a darke greene colour, ſharpe and pricking upon the tongue, and from the midſt of them ſeverall weake ſtalkes a foote or more long, upon whom grow ſmaller leaves and broader at the bottomes where they compaſſe them, ſet at ſeverall diſtances, at the toppes whereof come forth divers white flowers in a ſmall tuft ſtanding one above another, more ſeparate as they flower, making a long ſpike, and give ſmall long and round coddes, which parting into two parts, ſhew the ſmall reddiſh ſeede within them cleaving to each ſide: the roote is ſmall and creepeth ſpreading farre about.

5. *Draba alba ſiliquoſa minor.* The leſſer codded *Arabian* Muſtard.

This ſmaller ſort hath divers branches of leaves riſing from the roote which lying on the ground or a little covered with earth ſhoote forth ſmall fibres whereby it creepeth farre about: the leaves are broad at the point and ſmaller at the bottome, dented into ſome deepe dents or notches, the greateſt whereof are loweſt, of a grayiſh greene colour which ſo abide the firſt Winter, and then ſomewhat earely before the beginning of Summer following, from among them riſe ſundry upright ſlender hairy ſtalkes halfe a foote high, ſet with leſſer leaves which compaſſe the ſtalkes at the bottome, after which come ſlender long and round coddes, like to thoſe of the ordinary Muſtard, containing within them in a double row ſmall reddiſh ſeede: the roote is ſmall and white, ſending forth ſuch like branches of leaves yearely abiding all the Winter after.

6. *Draba Eryſimi flore & ſiliquis.* Baſtard *Arabian* Muſtard.

This ſmall plant hath divers ſuch like branches of hairy whitiſh leaves lying about the roote, ſlightly dented about the edges, every one on a ſmall foote ſtalke, from among which riſe up weake and ſlender ſtalkes, ſet with the like leaves and ſundry ſmall yellowiſh flowers at the toppes, whom ſmall long coddes doe follow, containing ſmall ſharpe ſeede: the roote is of the bigneſſe of a finger, white and long, ſet without, or with very few fibres.

7. *Draba lutea.* Yellow *Arabian* Muſtard.

The laſt plant is not ſo ſmall as this is great, ſhooting forth ſquare, but weake ſtalkes, foure or five foote long or more, not able to ſtand upright, but lie on the ground oftentimes, ſet orderly with long and ſomewhat broad greene leaves, a little hairy and dented about the edges, ſpreading many long branches, all of them ſtored

4 *Draba alba ſiliquoſa repens.*
The more creeping codded *Arabian* Muſtard.

5. *Draba alba ſiliquoſa minor.*
The leſſer codded *Arabian* Muſtard.

with

6. *Draba Eryſimi flore & ſiliqua.* Baſtard *Arabian* Muſtard.

7. *Draba lutea.* Yellow *Arabian* Muſtard.

with very ſmall yellow flowers, growing ſcatteringly at the toppes with ſome ſmall leaves among them, which turne into very ſlender and limber long pods, with very ſmall yellowiſh ſeede in them very ſharpe and biting upon the tongue: the roote groweth to be very great and ſomewhat wooddy, very ſtrong and fierce both in ſmell and taſte, abiding under ground many yeares, but looſing all ſtalkes and leaves above ground every yeare.

8. *Draba flore cæruleo galeato.*

Hooded *Arabian* Muſtard with blew flowers.

For ſome likeneſſe unto *Draba* is this plant referred hereunto, although in many things much differing: the roots conſiſt of many long white ſtrings and fibres like unto the *Aſclepias* Swallowort, of an hot but aromaticall and ſpicy taſte, which uſually ſendeth forth but one ſtalke, yet ſometimes two, ſtraight ſmooth and ſtraked, about halfe a yard high, ſpread into ſome few branches, bearing hoodded blew flowers like thoſe of Orchis or Dogs ones of an inch long, ſtanding on each ſide of them to the toppes: the lower greene leaves are about two inches long and ſcarſe one broad ſmooth and dented about the edges, but thoſe that grow up higher and but few upon the ſtalkes are narrower and more pointed.

The Place.

The firſt *Cluſius* ſaith he found as plentifully about the borders of the fields at *Vienna*, as others have done in other places, and ſo likewiſe the fourth and fift, the ſecond being not mentioned where it grew, the third was found about *Bononia*: the ſixt *Lobel* ſaith groweth not farre from *Mompelier*: the ſeaventh at *Tubing* neare the river *Neccar* about *Heidelberg* and *Bornis* in *Rhætia* among the *Switzers*: the laſt is naturall in certaine places of *Narbone* in *France*.

The Time.

They doe all flower in the moneths of *Iune* and *Iuly* and their ſeed ripeneth in the meane time.

The Names.

It is called in Greeke ἄραβις ἢ δράβη and ſome in Latine *Arabis* and *Draba* but from whence deduced it is not yet found out, although *Lobel* and *Fena* doe gheſſe much thereabouts: for divers writers have obſerved, that this herbe was never knowne to *Dioſcorides* nor mentioned by him, but thruſt into the text as I ſaid before by ſome later writers, for neither *Galen* nor *Oribaſius* who both followed *Dioſcorides* method, and wrote moſt of the ſame things make any mention thereof at all, no more doe *Ætius* nor *Paulus Ægineta* who in the ſame manner and order write of the ſame herbes with *Dioſcorides*, no nor *Pliny* neither who wrote out of *Dioſcorides* the moſt of his plants, yet *Cordus* thinketh that *Pliny* meaneth this plant under the name of *Driophonon*: beſides it is twiſe ſet downe in ſome Greeke copies that are manuſcripts, firſt in the Chapter next unto *Thlaſpi* in his ſecond booke, and then at the end of the ſame booke betweene *Glaſtum* and *Telephium*, yet howſoever it is, the herbe ſo named is well knowne now a dayes, and accepted by that name among all the moderne writers of herbes, and although *Doloneus* miſtook this and thought the *Thlaſpi creticum* to be it, yet others ſoone found his errour & avoided it. *Serapio* calleth it *Naſturtium Orientale*: the firſt is generally called *Arabis* and *Draba vulgaris* by all Authors, and *Naſturtium Babilonicum* by *Lobel*, *Bauhinus* calleth it *Draba umbellata*, *vel Draba major capitulis donata*: the ſecond is called by *Cluſius Draba minor* and by *Bauhinus Draba minor capitulis orbicularibus*: the third is called by *Bauhinus Draba tenuifolia veluti ſpicata*: the fourth is called by *Lobel Draba vel Arabis altera* and ſo by *Lugdunenſis*, and *Eruca muralis* by him alſo, by *Cluſius Draba tertia ſucculento folio*, and by *Bauhinus Draba alba ſiliquoſa repens*, who thinketh it may be the *Planta ſiliquifera Thlaſpeos generibus cognata* of *Thalius*, but *Thalius* himſelfe thinketh it may agree with *Lobel* his *Sinapi* and *Thlaſpi media planta*: the fift is *Cluſius* his *Draba ſecunda* which *Bauhinus* calleth *Draba alba ſiliquoſa*: the ſixt is that *Sinapi* and *Thlaſpi media Provincialis planta* of *Lobel* whom *Lugdunenſis* followeth & *Bauhinus* calleth *Draba Eryſimi flore & ſiliquis*: the ſeventh is mentioned by *Camerarius*, both in his Epitome upon *Matthiolus* & in his *Hortus medicus* alſo by the name of *Arabis quorandam floribus luteis*, and ſaith it may more fitly agree thereunto then unto the *Solidagines*, by which name he received it out of *England*, which maketh me much to ſuſpect that this *Draba lutea* is the ſame herbe that wee doe uſually here

here in *England* call *Solidago Saraſenica* and *Germanica ſiliquoſa*, it doth ſo nearely anſwer it in every part, which was alſo well knowne to *Gerard* in his time, although mentioned by him in a contrary place from the *Solidago Saraſenica*, namely in the Chapter of *Epimedium* Barren-wort, where hee compareth the cods of *Epimedium* unto the cods of *Saraſens* conſumed, meaning this plant and not that which he had deſcribed before for *Solidago Saraſenica*, whoſe ſeede he ſaith is blowne away with the winde. *Bauhinus* in his *Matthiolus* calleth it *Draba lutea*, and in his *Pinax Draba lutea ſtrictiſſimis ſiliquis*: the laſt *Bauhinus* hath onely mentioned by the name of *Draba flore cæruleo galeato*, which as I ſayd doth hardly or very little agree unto any *Draba*.

The Vertues.

The *Arabian* Muſtard being as ſharpe in taſte as any Thlaſpi, is accounted to be hot and dry, and thereby to bee as effectuall to all the purpoſes that Thlaſpi or Creſſes ſerve unto, and as it is in *Dioſcorides* if the Chapter be his is uſed in ſtead of Pepper to put among broths and meats, and alſo being boyled with Ptiſane, is availeable to cu tough flegme that ſticketh in the breaſt and lungs, cauſing it to be eaſely expectorate and ſpit forth.

CHAP. XIX.

Turritis ſive Turrita. Towers Muſtard.

OF this herbe there are two or three ſorts mentioned by ſome writers, whereof ſome of them referr them as *Bauhinus* doth unto the kinds of wilde Coleworts, to whoſe cenſure I cannot ſo readily a gree, in that the herbe in part but the ſeede chiefly is as hot and ſharpe in taſte as the *Thlaſpi* or *Dra ba*, and therefore fitteſt to be joyned next thereunto as comming neareſt unto their family.

1. *Turritis vulgatior.* The more common Towers Muſtard.

This more common ſort of Towers Muſtard hath many rough hairy leaves full of ſappe or juice, of a deep greene colour about two inches long and more then one broad, pointed at the ends and broadeſt in the middle, littl or nothing dented about the edges, lying round about the head of the roote upon the ground, from among whic riſe up divers rough and hairy ſtalkes neare two foote high, ſet orderly with ſuch like leaves one above anoth on all ſides thereof, but compaſſing them at the bottome which are narrower & longer pointed then thoſe below at the toppes of the ſtalkes which are ſeldome branched, grow many very ſmall white flowers as it were in a tu together, but flower by degrees the loweſt firſt, and bring forth long ſlender cods preſently after, which ſtandir upright round about the ſtalkes before the higheſt flowers are blowne, the whole ſtalkes ſeeme like *Pyramide* Steeples or Towers from whence it tooke the name, in which cods are contained ſmall browne and ſharpe b ting ſeed: the root is compoſed of many white fibres or ſtrings ſeldome abiding after it hath given ſeede there

1. *Turritis vulgatior.* Common Towers Muſtard.

2. *Turritis major.* The greater Towers Muſtard.

but being ſhed, there doth ſpring up divers plants before winter, and ſo abide to flower and ſeede the next Sommer.

2. *Turritis major.* The greater Towers-Muſtard.

This greater ſort ſpreadeth many leaves upon the ground ſomewhat greater & longer, and not ſo rough or hairy as the former, ſomewhat crumpled and waved about the edges, and of a paler or whiter greene colour, almoſt of the colour of the field Coleworts (which onely thing in my opinion cauſed *Bauhinus* and others to referre theſe ſorts unto the wilde Coleworts) the ſtalkes riſe higher and more branched, the leaves on them compaſſing them at the bottomes, much more than the former, bearing ſmall whitiſh yellow flowers at the toppes, and long ſlender cods like unto the other after them, but ſomewhat longer more crooked, and not growing up ſo ſtraight about the ſtalkes, but more looſely or ſparſedly, containing within them ſomewhat larger ſeede and not altogether ſo fierce and ſharpe: the roote is white and thicke with fibres growing about it, which periſheth and is raiſed againe in the ſame manner.

3. *Turritis Alpina.* Mountaine Towers-Muſtard.

This ſmall mountaine Towers Muſtard groweth up with a ſmall ſmooth round ſtalke little above a ſpanne high, having divers ſmall leaves at the foote thereof ſlightly waved about the edges, and of a pale greene colour, longer alſo than thoſe that grow upon the ſtalke which are not many, and they ſmaller and ſhorter and without foote ſtalkes; at the toppes whereof ſtand many ſmall white flowers ſo cluſtering that they forme a ſhort ſpike, every one ſtanding on a long foote ſtalke: the coddes have not beene well obſerved: the roote is ſmall and white.

The Place.

The firſt delighteth to grow more on the open Sunnie hills, and the ſecond more in the woodes and ſhadowye places, and both in *Auſtria* plentifully as *Cluſius* ſaith where the laſt was found alſo.

The Time.

Theſe flower early for the moſt part ſometime in *Aprill* but uſuall in *May*, and the ſeede is ripe in *Iune*.

The Names.

Theſe herbes have not beene knowne to any of the ancient Herbariſtes either Greeke or Latines, neither yet to many of our moderne Writers, for I finde none of them to make mention thereof by the name of *Turritis* or *Turrita*, but *Lobel* in his *Dutch* Herball, *Cluſius*, *Tabermontanus*, and *Gerard* from him whoſe figures were uſed for his Herball, and *Bauhinus* laſt of all, who yet, as I ſaid in the beginning of the Chapter referreth them rather to the kindes of *Braſſica ſylveſtris* wilde Colewortes. The firſt is called by *Cluſius Turrita vulgatior*, and *Turritis* by *Lobel*, *Tabermontanus* calleth it alſo *Vaccaria*, and *Bauhinus Braſſica ſylveſtris foliis integris & hiſpidis*: the ſecond is called *Turrita major* by *Cluſius*, but *Thalius Braſſica ſylveſtris procera*, and *Bauhinus* following *Thalius* rather than *Cluſius* calleth it *Braſſica ſylveſtris ramoſa tota penè glabra*: *Bauhinus* calleth the laſt *Braſſica ſylveſtris Alpina*, although as he ſaith it was ſent him by a skilfull Herbariſt by the name of *Turritis Alpina*.

The Vertues.

The fierce ſharpeneſſe of theſe herbes, and eſpecially the ſeedes doe plainely declare them to bee *congeneres* to the Muſtards, Creſſes, *Thlaſpi*, and the like, and no doubt will worke the ſame effects, although I have no author from whom I might declare any ſpeciall properties in them, and therefore I leave them to every ones practiſe to experiment their vertues.

CHAP. XX.

Iberis Cardamantica. Sciatica Creſſes.

SCiatica Creſſes are of two ſorts, of both which *Matthiolus* entreateth but in ſeverall places, the one in the end of the firſt booke under the title of *Iberis*, the other under *Lepidium* in the ſecond booke.

1. *Iberis Naſturtij folio.* Sciatica Creſſes.

This *Iberis* riſeth up with a round ſtalke about two foote high ſpread into divers branches, whoſe lower leaves are ſomewhat larger than the upper, yet all of them cut or torne on the edges, ſomewhat like unto Garden Creſſes but ſmaller: the flowers are ſmall and white growing at the toppes of the branches, where afterwards grow huskes like unto Creſſes, with ſmaller browniſh ſeede therein than in the other, very ſtrong and ſharpe in taſte more than the Creſſes: the roote is long, white and wooddy.

2. *Iberis latiore folio.* Sciatica Creſſes with larger leaves.

This other hath the lower leaves whole, ſomewhat long and broad not rent or torne at all, but onely ſomewhat deepely dented about the edges towards the ends very like unto thoſe of *Thlaſpi Creticum* ſet forth here before among the *Thlaſpies*, but thoſe that grow up higher are leſſer: the flowers and ſeede are like the former, and ſo is the roote likewiſe, and both roote and ſeede as ſharpe as it.

The Place.

Theſe grow by the wayes ſides in untilled places, and by the ſides of old walles, &c.

The Time.

They flower in the end of *Iune*, and their ſeede is ripe in *Iuly*.

The Names.

It is called in Greeke by *Dioſcorides* Γ'ερὶς ἡ καρδαμαντικὴ, *Iberis ſive Cardamantica quod Cardamo, id eſt, Naſturtio ſimilis eſt* (and ἄγειον κάρδαμον *Naſturtium ſylveſtre*) if the text be *Dioſcorides* his owne, which is plainely convinced not to be by good reaſons, becauſe by the teſtimonie of *Galen Iberis* and *Lepidium* are all one (for in his tenth Booke *De comp. medicam ſecundum locos*, from the authority of *Hygienus Hipparcus*, hee ſaith thus: *Si coxendicum dolores levare eſt animus, herbam Iberidem quam aliqui Lepidium vocant, aut Naſturtium ſylveſtre colligito, &c.* and *Dioſcorides* hath a Chapter in his ſecond Booke entituled for *Lepidium*, ſo that he would not ſpeake of one herbe in two places, beſides this *Iberis* is thruſt into theend of his firſt Booke, which doth not in qualitie ſort with the reſt of the herbes there ſet downe before. *Galen* alſo in his booke *De ſimplicium cenſu*, doth never intreate of them ſeverally as of two herbes, but ſtill as of one. *Paulus Æginita* likewiſe ſaith that *Lepidium* was called *Iberis*, being hot in the fourth degree and neare unto

1. *Iberis Naſturtij folio.*
Sciatica Creſſes.

2. *Iberis Cardamantice latiore folio.*
Sciatica Creſſes with larger leaves.

Creſſes in the properties: and in his third Booke and 77. Chapter, ſpeaking *De Iſchiadis curatione*, he ſaith, *In totum iſchiadicos ſanitati reſtituit Iberidis herbæ uſus quam Lepidium quoq; vocant*: they therefore that ſeparate them and make them different herbs are in an errour, but the ſaid *Paulus Æginita* in the ſame Booke and place ſheweth that there is another *Iberis* ſaying, *Iberis fruticoſa quæ apud nos naſcitur Lauri foliis ſimilibus & multo ampliori-bus reſpondere multis teſtimonia teſtantur, non ſolum in coxarum ſed in alijs quoque diuturnis affectibus*; which *Iberis* or *Iberias altera* is very likely to be the *Lepidium* of *Pliny* in his 19. Booke and 8. Chapter, whereof he ſaith thus, *Exit Lepidium in cubitalem altitudinem foliis Laurinis*, which *Lepidium*, by the judgement of the beſt of the later Writers is that herbe which ſome call *Piperitis*, and ſome *Raphanus ſylveſtris*; in *Engliſh* Dittander, whereof I ſhall ſpeake in the next Chapter. *Damocrates*, as *Galen* ſheweth firſt, called it *Iberis*, becauſe he cured a friend of his in *Iberia* with this herbe, which he learned of another who knew not the name thereof, and therefore *Damocrates* in a Booke of his called *Clinicus* ſetteth downe in *Iambicke* Verſes both the forme of the herbe, and the place of growing, that others might know it, and the manner of the cure alſo for others to follow, which here to recite were too tedious. *Pliny* calleth it *Hiberis* miſtaking the accent over the *Iota*, as it is likely. It is thought alſo by ſome that it is the *Grias Apuleij*. *Matthiolus* giveth the figure of the firſt in his greater figures, and of the other in his leſſer: *Anguilara* calleth the firſt *Lepidium campeſtre*, *Tabermontanus Iberis ſecunda*, *Durantes Iberis*, and *Gerard Iberis Cardamantica*, but *Bauhinus Iberis Naſturtij folio*: the other is called *Iberis* by *Lugdunenſis*, *Dodonæus*, *Lacuna*, *Geſner in hortis* and *Cæſalpinus*, who yet ſaith it is *Lepidium forte Columellæ*; by *Anguilara Lepidium hortenſe*; by *Lobel Iberis Cardamantica Lepidium Iberias Pauli*; and by *Bauhinus Iberis latiore folio*: the *Arabians* call it *Seitaragi* and *Hauſab*: the *Italians Iberride* and *Lepidio*; the *Spaniards Maſtuerſo monteſino*; the *French Paſſerage ſonnage* and *Naſitort*; the *Germanes Wilderkerſſ*; the *Dutch Seiatica Kerſſ*; and we in *Engliſh* likewiſe Sciatica Creſſes.

The Vertues.

The leaves, but eſpecially the rootes while they are freſh taken in the Summer time, beaten and made into a pultis or ſalve with old *Axungia* or Swines greaſe, and applied to the place pained with the Sciatica, to continue thereon for foure houres in men, and two houres in women, the place afterwards bathed with wine and oyle mixed together, and then wrapped with wooll or skinnes after they have ſweate a little, will aſſuredly cure, ſaith *Galen* from *Damocrates*, not onely the ſaid diſeaſe in the hippes and hucklebone, and others of the joynts, ſuch as is the gout in the hands or feete, but all other old griefes of the head, as inveterate rheumes, or in any other part of the body that is hard to be cured, and ſaith alſo that *Damocrates* cured hereby all thoſe diſeaſes wherunto were *Sinapiſmes* uſed or *Thapſia* applied: *Pliny* reciteth the ſame method and manner that *Damocrates* uſeth in his Verſes, and ſaith that if any part of the griefe remaine, the ſame medicine after 20. dayes, is to be applied againe: the ſame alſo is effectuall in the diſeaſes of the ſpleene: and applied to the skinne it taketh away the blemiſhes thereof, whether they be ſcarres, or leproſie, or ſcabbes, or ſcurfe, &c. which although it exulcerate the part, yet that is to be helped afterwards with a ſalve made of oyle and waxe. *Dioſcorides*, and *Pliny* from him ſay, that if the roote be hung about the necke, or tied to the arme it will eaſe the paines of the tooth-ach.

CHAP.

CHAP. XXI.

Lepidium ſive Piperitis. Pepperwort or Dittander.

HAving ſhewed you in the laſt Chapter that there is another *Lepedium* differing from *Iberis*, I thinke it meete to ſhew you which it is, and place it next thereunto, and together with it expreſſe ſome others, that for their likeneſſe and properties have obtained the ſame name.

1. *Piperitis ſive Lepidium vulgare.*
Dittander or Pepperworte.

Our common Pepperworte called Dittander, ſendeth forth ſomewhat long and broad leaves, of a light blewiſh greene colour finely dented about the edges and pointed at the ends, ſtanding upon round hard ſtalkes three or foure foote high, ſpreading many branches on all ſides, and having many ſmall white flowers at the toppes of them, after which follow ſmall ſeede in ſmall heads: the roote is ſlender running much under ground, & ſhooting up againe in many places, and both leaves and roote are very hot and ſharpe in taſte like unto Pepper, for which cauſe it tooke the name.

2. *Lepidium Monſpeliacum Dentellaria dictum.*
French Dittander or Scarre-worte.

This herbe which is uſually called *Dentellaria Rondeletij ſive Narbonenſium*, ſendeth forth a number of long and limber ſtalkes, reddiſh at the bottome, and lying downe upon the ground, and not ſtanding upright by reaſon of the length, which in my Garden became five or ſixe foote long ſet with leaves on all ſides of them, being ſomewhat narrow, long, and ſmooth, of a ſadde greene colour ſmaller at the lower end, and compaſſing the ſtalkes about, but

1. *Pipperitis ſive Lepidium vulgare.*
Pepperwort or Dittander.

2. *Lepidium Monſpeliacum Dentellaria dictum.*
French Dittander or Scarre-worte.

3. *Lepidium annuum.*
Annuall Dittander or Scarre-worte.

leſſer ſtill up higher to the toppes, where they are a little branched, and doe beake forth into divers darke purpliſh flowers ſet together, conſiſting of five ſmall pointed leaves a peece ſtanding in rough browniſh huskes, wherein afterwards is contained ſmall round and blackiſh ſeede very ſharpe in taſte, exulcerating the skinne and burning it being layd thereon as the leaves doe alſo; the roote is compoſed of many great ſtrings with a wooddy pith in the middle, running downe deepe into the ground and abiding many yeares, although both ſtalkes and leaves periſh every yeare gaining freſh in the Spring.

3. *Lepidium annuum.* Annuall Dittander or Scarrewort.

This Dittander or Scarrewort hath ſtalkes more upright then the laſt, three or foure foote high, ſet with ſuch like leaves as the laſt but ſomewhat larger and compaſſing them at the bottomes: the flowers are white, and ſtand upon ſmall branches ſpike faſhion one above another, which afterwards give ſmall round and pointed huskes like ſome of the *Thlaſpies*, wherein the ſeede is contained no leſſe hot and fierce in taſte, and exulcerating the skin then in the former: the roote is ſmall and fibrous periſhing yearely.

The Place.

The firſt is found naturally growing in many places of this Land, as at *Clare* in *Eſſex*, neare *Exeſter* alſo, and upon *Rocheſter* Common in *Kent*, at *Sawle Abbey* neare *Whawley* in *Lancaſhire*, and in other places, but is uſually kept in Gardens: the other two are found about *Mompelier* in *France*.

The Time.

The firſt flowreth in the end of *Iune* and in *Iuly*, but the ſecond very late with us in *Auguſt*, and never gave ripe ſeede in *England* that ever I knew: the laſt flowreth in *July* and the ſeede is ripe in *Auguſt*.

The Names.

Λεπίδιον *Lepidium* in Greeke is ſo called as it is thought *quod* Λεπίδας *id eſt, maculas & ſquammas in cute delent*, or as others thinke ἀπὸ τῦ λεπίζειν *quod acrimonia urenti ulceret Lepidium* alſo in Latine, yet this is not the *Lepidium* of *Dioſcorides* and *Galen* which is a ſmaller herbe even the ſame I ſhewed you in the laſt Chapter, but is that *Iberis fruticoſa* of *Paulus Ægineta*, and *Pliny* his *Lepidium folijs laurinis* alſo, as I ſhewed you before: The firſt is called *Piperitis* by *Fuchſius* and *Lonicerus*, by *Tragus*, *Matthiolus* and *Camerarius Lepidium ſive Piperitis*, and *Lepidium magnum* by *Fuchſius*, *Turner* and *Cordus in Hiſtoria*, *Anguilara* tooke it to be *Lepidium Dioſcoridis*, it is *Lepidium Plinij* by *Lobel* and *Dodonæus*, and *Lepidium Pauli & Plinij*, by *Matthiolus*, *Lugdunenſis* and *Cæſalpinus*, by *Lobel Raphanus ſylveſtris officinarum*, and by *Bauhinus Lepidium latifolium*: the ſecond is called *Dentellaria Monſpeliaca*, by *Geſner in hortis* and *Flammula*, who ſaith it is called at *Rome Herba Sancti Anthonij*, by *Lobel* and *Lugdunenſis*, *Dentellaria* and *Dentaria Rondeletij* and *Narbonenſium*, *Molybdena Plinij* by *Anguilara* and *Camerarius*, who alſo ſaith it is called *Crepanella* by the *Italians*, *Cluſius*, *Durantes* and *Tabermontanus* call it *Plumbago* and *Plumbago Plinij*; *Bellonius* ſaith that they of *Candy* call it *Saxiphago* they of *Lemnos Phrocalida*, and they of *Leſbos Manronia*, *Cæſalpinus* calleth it *Glaſtum ſylveſtre* and *Bauhinus Lepidium Dentellaria dictum*, the laſt is called by *Lobel Lepidium annuum*, and ſo alſo by *Lugdunenſis*, but by *Bauhinus Lepidium glaſtifolium*. Wee uſually call the firſt in *Engliſh* Dittander and Pepperwort, but the other two may be called in *Engliſh* from the Greeke etymologie Scarrewort, eyther becauſe it will make a marke in the hand of them that ſhall hold it a while, or that it will take away markes and ſcarres of wounds, ſores, or burnings in the fleſh.

The Vertues.

All theſe herbes are as hot and fiery ſharpe as the laſt and worke the ſame effects, for both *Paulus Ægineta* and *Pliny* ſay, that they are as effectuall for the Sciatica or Hip-goute or any other goute or paine in the joynts, or any other inveterate greeſe, the leaves hereof to bee bruiſed and mixed with old *Axungia*, and applyed in the ſame manner, and uſed in the ſame order that the Sciatica Creſſes are appointed before: the ſame alſo amendeth the deformities or diſcolourings of the skinne, and helpeth to take away markes, ſcarres, and ſcabbes or the fowle markes of burnings with fire or *Iron*. The women of *Bury* in *Suffolke* doe uſually give the juice thereof in Ale to drinke to women with child to procure them a ſpeedy delivery in travaile. The others are judged by the learned men at *Mompelier* to be alſo of the ſame effect, for ſome of them tooke that of *Rondeletius* to bee the right *Lepidium* of *Dioſcorides*, whereunto ſuch vertues are attributed by *Rondelitius*, who made as good uſe thereof for the tooth ach as he did of Pellitory of *Spaine*, and moreover by holding ſome of the leaves in their hands that had the toothach did give them eaſe, and withall raiſe a marke or wanne diſcolouring in the palme of the hand, and leave it ſo after it was caſt away.

CHAP. XXII.

Hydropiper ſive Perſicaria. Arſmart.

BEcauſe the laſt herbe was called *Piperitis* I thought good to joyne theſe, and although in former times there were onely two ſorts of Arſmart knowne to all Herbariſts, yet ſince them *Lobel* hath added a ſmall one, *Bauhinus* a fourth, and we to increaſe their number are to joyne divers others unto them.

1. *Perſicaria vulgaris acris ſive minor.* Ordinary quicke or ſharpe Arſmart.

The quicke or ſharpe Arſmart groweth not ſo high or great as the mild ſort doth, but with more ſtore of branches and leaves, ſomewhat like unto Peach leaves, and are long and ſomewhat narrower then the other, and moſt uſually without any ſpot at all upon them, yet ſometimes it hath beene found with reddiſh markes upon the leaves: at the greater joynts as well towards the toppes of the ſtalkes, as at the toppes alſo come forth ſmall ſpikie heads of bluſh coloured, and ſometimes more red or white flowers mixed or cluſtering together, which falling away, blackiſh flat ſeede come in their places: the roote is ſomewhat long with many fibres thereat, which as well as the reſt of the plant is of a very ſharpe and quicke taſte, biting the tongue more then Pepper.

2. *Perſicaria vulgaris mitis ſive maculoſa.* Ordinary ſpotted Arſmart.

This other Arſmart hath ſomewhat broader leaves ſet at the great red joynts of the ſtalkes, with ſemicircular blackiſh markes on them uſually yet ſometimes without: the flowers grow in ſomewhat longer ſpikes uſually, eyther

eyther bluſh or whitiſh with ſuch like ſeede following: the roote alſo is of the ſame faſhion and both periſhing yearely: this hath no ſharpe taſte at all, but rather ſower like Sorrell, or elſe a little drying or without taſte.

3. *Perſicaria Anguſtifolia.* Narrow leafed Arſemart.

This ſmall Arſemart hath reddiſh ſtalkes of a cubits height, with much narrower leaves at the joynts then the former, and at their toppes ſuch cluſter-like heads of bluſh flowers but leſſe by a great deale: the roote is blackiſh and threddy.

4. *Perſicaria puſilla repens.* Small creeping Arſmart.

This other ſmall Arſmart ſtandeth not upright at all as the former doe, but leaneth downewards with the weake branches, which together with the ſmall long narrow leaves are not by the halfe ſo great as either of the two firſt, and differeth not but in the ſmalneſſe from them with ſometimes white and ſometimes purpliſh flowers.

5. *Perſicaria acris Virginiana.*
Sharpe Arſmart of *Virginia.*

This Arſmart of *Virginia* is in moſt things like the firſt, with long narrow leaves, but the flowers grow on more ſlender and long ſpikes and wholly white.

6. *Perſicaria fruteſcens maculoſa Virginiana, flore albo.*
Shrub ſpotted Arſmart of *Virginia* with white flowers.

This ſort of *Virginia* Arſmart riſeth up with ſundry hard round greene ſtalkes with the like great joynts on them as the others have, and faire large broad darke blewiſh greene leaves with ſmall long points on them, ſpotted oftentimes like the common ſort, and often alſo without markes, in many ſix inches long or better, and three and a halfe broad, with ſundry compaſſing veines from the middle ribbe, and others leſſer and tranſverſe: at the toppes of the ſtalkes and from the joynts with the leaves likewiſe, ſpring branches of ſpiked white flowers, like cloſe graines as in the

1. 2. *Perſicaria vulgaris vrens & mitis ſive maculata.*
Ordinary quicke or ſharpe Arſmart, and the ſpotted or mild ſort.

6. 7. *perſicaria fruteſcens maculoſa Virginiana flore albo & flore carneo.*
Shrub ſpotted Arſmart of *Virginia*, with white and with bluſh flowers.

4. *Perſicaria puſilla repens.* Small creeping Arſmart.

Dadd 3

other

other but greater, ſucceeded by the like blacke and flat ſhining ſeede: the roote conſiſteth of a great buſh of long blacke ſtringes and threads which periſh not yearely as the former doe, but abide from yeare to yeare, yet oftentimes the ſtalkes with leaves above ground dye downe and riſe afreſh in the Spring.

7. *Perſicaria altera fruteſcens longifolia maculata Virginiana flore carneo.*

This other *Virginia* Arſmart groweth up with ſtraight round ſtalkes, much higher than the laſt, with much longer and narrower leaves, marked alſo oftentimes in the like manner, and often alſo without: this is more plentifull in branches of flowers, which are ſhorter ſpikes but thicker ſet, with fine bluſh coloured flowers, much larger than in any of the former, but gave no ſeede with the Gentleman Mr. *Iohn Morrice* of *Iſſelworth*, that had it riſen from the ſeede that was ſent him from a friend in *Virginia*: the roote is greater and more woody than the laſt, and periſhed with the extremitie of the hard winter froſt.

The Place and *Time.*

The former two ſorts grow almoſt every where with us in watery plaſhes, ditches, and the like, that for the moſt part are drie in Summer: the third in *Germany*: the fourth in the like places about *Antwerpe*, as *Lobel* ſaith: the three laſt ſorts came from *Virginia*; the former ſorts flowring in *Iune*, and their ſeede being ripe in *Auguſt*; but the other ſorts flower much later with us, and ſcarce perfect their ſeede except the fift.

The Names.

It is called in Greeke ὑδροπίπερι, *id eſt*, *Piper aquaticum*, many doe call it alſo *Hydropiper* in *Latine*, and generally *Perſicaria a foliorum formæ*, yet ſome diſtinguiſh them, calling the milde or gentle ſort *Perſicaria* ſimply, and the other *Hydropiper* or *Perſicaria urens*, as *Lobel* doth, or *mordax* as *Thalius* doth: ſome as *Lugdunenſis* ſaith would make the ſpotted ſort to be *Plumbago Plinij*, becauſe of the leaden-like ſpots on the leaves, but they are much deceived: ſome alſo call it *Britanica Plinij*, but they are as farre wide as the other: *Lacuna* calleth it *Crataogonum*, and *Anguillara* calleth the ſharpe ſort by that name of *Crataogonon*, and by ſome *Zingiber caninum*: the third is onely remembred by *Bauhinus*, the fourth by *Lobel*, and the three laſt by no other before: the *Italians* call it *Perſicaria*, the *Spaniards Munchas*, the *French Culrage*, the *Germans Waſſer pfeffer*, and *Muckenkraut*, the *Dutch Watter poper*, and we in *Engliſh* Water pepper and Arſmart, and in ſome countries Red-knees.

The Vertues.

The milde Arſmart is of a cooling and drying qualitie, and the other contrarie is hot and drie: the firſt is very effectuall for putrid ulcers, either in man or beaſt to kill the wormes, and clenſe the putrified places; the juyce thereof dropped in, or otherwiſe applied, it likewiſe conſumeth all cold ſwellings, and diſſolveth the congealed bloud of bruiſes by ſtrokes, falls, &c. a peece of the roote, or ſome of the ſeede bruiſed and held to an aking tooth taketh away the paine: the leaves bruiſed and laid to the joint that hath a felon thereon taketh it away: the juyce dropped into their eares that have wormes in them deſtroyeth them quickly: if the herbe be ſtrowed in a chamber it will ſoone kill all the Fleas therein; and if the herbe or juyce thereof be put to horſes or other cattelles ſores, it will drive away the Flyes that will ſticke thereto, even in the hotteſt time of Summer: a good handfull of the herbe put under a horſes ſaddle, will make him travell better, although hee were halfe tired before. The milde Arſmart is held to be good againſt hot empoſtumes and inflammations at the beginning, and to heale greene wounds.

CHAP. XXIII.

Ptarmica vulgaris. Common field Pelletory or Sneeſeworte.

NExt unto Dittander ſhould follow Tarragon called *Tarchon* and *Dracunculus hortenſis & eſculentus* being of the like hot and ſharpe biting taſte, but that I have entreated therof in my former Book, as alſoof the garden Dragons, whoſe figure I herewith ſhew you, & muſt in this Chapter ſhew you the *Ptarmica vulgaris*, ordinarily called wilde Pelletory and Sneeſeworte, of which kinde alſo I have ſet forth one with double flowers in my former Booke. *Pyrethrum* alſo *vulgare*, called by us Pelletory of *Spaine*, although ſet forth in my former Booke. Vnto this I muſt adde an other ſtranger ſcarce knowne ſo much as by name to our Nation. This common Pellētory ſhooteth forth divers brittle ſtalkes a yarde high and more ſpread into ſundry branches, whereon are ſet narrow long leaves pointed at the ends, and finely dented about the edges ſtanding one above another up to the toppes, where grow many white flowers in a round tuft together, ſomewhat like unto thoſe of Yarrow or Millfoyle, with a very ſmall yellowiſh thrumme in the middle, bordered about with very ſhort whitiſh leaves dented in at the broad ends, which paſſing away leave behinde them ſmall heades with chaffie ſeede therein: the roote is long and whitiſh joynted at ſeverall diſtances, creeping farre about under ground: both leafe and roote are of an hot ſharpe biting taſte, like unto the true Pelletory of *Spaine* whereof it tooke the name.

2. *Pyrethrum vulgare officinarum.* Pelletory of *Spaine.*

This is a ſmall low plant bearing many finely cut long leaves upon the ſtalkes lying on the ground, much larger than Camomill, bearing at the toppes of each one ſingle large flower having a pale or border of many leaves, white on the upperſide, and reddiſh underneath ſet about the middle yellow thrumme, but not ſtanding ſo cloſe joyned at the bottome as the Camomill flowers doe, but more ſevered one from another: it beareth ſmall whitiſh ſeede which is hardly found and diſcerned from the chaffe: the roote is long growing downeright of the bigneſſe of a mans finger or thumbe in our countrie, but not halfe ſo great where it groweth naturally, with divers fibres from the ſides, of a very hot, ſharpe, and biting taſte, drawing much water into the mouth being a while chewed after it hath beene dried, but nothing ſo much while it is freſh and greene: the plant is very tender with us not enduring our Winter, unleſſe it be very carefully preſerved.

3. *Ptarmica Alpina ſive Dracunculus Alpinus Scabioſæ folio.* Wilde Pelletory with Scabious leaves.

This mountaine Pelletory hath round ſtalkes about a foote high, ſpreading ſome branches towards the toppes, whereon are ſet divers long pale greene leaves on both ſides one above another as in the former; but jagged or deepely cut in on both ſides, ſomewhat like unto a Scabious leafe: at the toopes of the ſtalkes and branches ſtand

the

Ptarmica vulgaris. Common field Pelletory or Sneesewort.

Draconculus major vulgaris. Ordinary Dragons.

the flowers somewhat larger than the other, else not much unlike having a border or pale of white leaves, set about a middle thrumme: the roote hereof is more stringy and fibrous than the other.

The Place.

The first groweth in fields and medowes by the hedge sides and path wayes almost every where, and in lanes also and wast grounds, the other in *Spaine* and divers other countries: the last was found in the mountainous fields of *Helvetia* or *Switserland* and other parts there abouts.

The Time.

The first and last flower in the end of *Iune* and in *July*, and the second not untill *August* with us, and seldome giveth ripe seede, unlesse carefully preserved in the Winter.

The Names.

It is called in Greeke πταρμικὴ *Ptarmica, quod est Sternutatoria,* or *Sternutamentoria,* as it is also in *Latine* from the effect of provoking sneesing. The first is diversly called by divers. *Tragus* calleth it *Tanacetum album sive acutum, & Millefolium primum, Gesner in hortis Tarchon sylvestre vel aquaticum, & in collect. stirpium Draco aquaticus, Brunfelsius Pyrethrum, Cordus* on *Dioscorides Pyrethrum sylvestre, Dodonæus Draco sylvestris sive Ptarmica, Bauhinus* referreth it to that plant which *Lugdunensis* calleth *Menthæ Saracenicæ species altera Myconij,* and yet maketh it also a kinde of *Costmarie*; *Thalius Ptarmica sylvestris Germanica, Clusius Ptarmica pratensis, Lobel Ptarmica folio Taraconis vel Sternutamentoria, Matthiolus, Fuchsius, Gesner,* and others *Ptarmica,* and *Bauhinus Dracunculus pratensis serrato folio*: the second is called by all Authors *Pyrethrum,* and of some *Salivaris,* but *Gesner in hortis* addeth *Germanicum,* as it is thought *Matthiolus, Lugdunensis* and all other *alterum, Lobel officinarum,* and *Bauhinus flore Bellidis*: the last is set forth onely by *Bauhinus* who calleth it *Dracunculus Alpinus folio Scabiosæ*: it is called by the *Arabians Macarcaraha,* or *Hacharcharha,* by the *Italians Riretro,* by the *Spaniards Pelitre,* by the *French Pie d' Alexandre,* by the *Germans* and *Dutch Bertram*; it is called in *English* wilde Pelletory, or wilde Pelletory of *Spaine,* as the second is called the true Pelletory of *Spaine.*

2. *Pyrethrum vulgare officinarum.* Pelletory of *Spaine.*

The

The Vertues.

Wilde Pelletory is hot and dry in the ſecond degree while it is freſh and greene, but in the third degree when it is dry. An ounce of the juice hereof taken in a draught of Muſcadine an houre or two before the fit of an Ague and preſently layd to ſweat, will aſſuredly drive away the Ague at the ſecond or third time taking at the fartheſt: the herbe dryed or the roote chiefly chewed in the mouth draweth downe from the head much flegme, and is thereby availeable to eaſe the paines in the head and teeth, and to draw forth cold rheume, catarrhes and defluxions upon the Lungs or diſtillations into the eyes, it mightily alſo purgeth the braine from thoſe humours that are the cauſe of the Appoplexie and Epilepſie or falling ſickneſſe: it helpeth alſo to conſume the ſuperfluous moyſture of the head and braines, that falling into other parts of the body is the cauſe of many diſeaſes and much trouble thereunto: the powther of the dryed herbe or roote put up into the Noſtrills procureth ſneezing, which oftentimes doth eaſe the head-ach, the leaves or flowers bruiſed and made into a ſalve or poultis with old Hogs greaſe, being applyed taketh away blacke and blew ſpots that come by ſtroakes or falls or bruiſes, as alſo all other ſores or blemiſhes in the skinne, and is alſo good for the Goute and Sciatica. The true Pelletory of *Spaine* is moſt commonly uſed for the toothach, by the root it ſelfe or with other things to bee chewed in the mouth, *Galen* ſaith it is to be uſed with oyle, and rubbed on the parts that have ſhaking fits of Agues.

CHAP. XXIIII.

Raphanus Ruſticanus. Horſe Reddiſh.

THe kinds of Garden Reddiſh I have declaed in my former Book, & therefore need not to deſcribe the againe, but onely to ſhew you their Figures and with them the Horſe Reddiſh, whoſe firſt leaves that riſe up before Winter are about a foote and a halfe long, narrower and very much cut in or torne on the edges into many parts, of a darke greene colour with a great rib in the middle, but after theſe have beene up a while others follow which are greater, rougher, broader and longer, whole and not divided as the firſt, but onely ſomewhat roundly dented about the edges: the ſtalke when it doth beare flowers as it doth but ſeldome is great, riſing up with ſome few leſſer leaves thereon to the height of three or foure foote, ſpreading at the toppe many ſmall branches of whitiſh flowers made of foure leaves a peece, after which come ſmall pods like thoſe of the leſſer Shepherds purſe, but ſeldome with any ſeede in them: the roote is great, long, white and rugged, ſhooting up divers heads of leaves which may be parted for increaſe, but it doth not creepe within the ground, nor run above ground, and is of a ſtrong ſharpe and bitteriſh taſte almoſt as Muſtard.

Raphanus ruſticanus. Horſe Reddiſh.

The Place.

It is found wilde in ſome places of this Land, but is chiefly planted in Gardens where it joyeth in a moyſt and ſhadowy place.

The Time.

It flowreth as I ſayd but ſeldome, but when it doth it is in *July*.

The Names.

It hath no Greeke name that I can finde, for if *Dioſcorides* his Copies bee true it cannot bee his *Raphanus ſylveſtris*, called by the *Romans Armoracia*, for hee maketh the roote thereof to bee ſmall, and the leaves tender and fit to bee eaten which cannot agree hereunto, yet *Tragus* is confident that it is the *Armoracia* of *Pliny*, and thinketh withall that it is the *Thracia radix* and *Liothalaſſion* of *Theophraſtus lib.7.cap.4.* which *Pliny* referreth to the Turneps. It is called *Raphanus Ruſticanus* by *Lobel*, and *Raphanus vulgaris* and *Ruſticanus* by *Matthiolus*, by *Dodonæus Raphanus magna* and *Radicula magna*, *Armoracia aut Raphanus major* by *Brunfelſius*, *Raphanus major* by *Tragus* and *Geſner*, *Cordus* upon *Dioſcorides* and *Lonicerus* call it *Thlaſpi majus* and *magnum*, and *Bauhinus* doth in part ſo judge of it alſo, for he calleth it *Raphanus Ruſticanus Thlaſpi alterum Dioſcoridis lib.2.cap.13.* But *Pliny* in his 19. booke and 15. Chap. hath faulted much, in reciting the kinds of Reddiſh with the Græcians to make three which he taketh out of *Theophraſtus lib.7.c.4.* where he by the word ῥάφανος doth not underſtand Reddiſh but Cabbage as the learned doe well know that reade him, and that ῥάφανις with him is as it is thought *Raphanus* Reddiſh, whereof in the ſame Chapter he mentioneth five ſorts, *Corinthia*, *Cleonæa*, *Liothalaſſia*, *Bœotia* and another wild ſort with Rocket-like leaves which *Athenæus* calleth *Amorhea*, and *Pliny* inverting the word *Raphanus*

the Greek call it ραφανὶ Rapany

to

Raphanus vulgaris. Ordinary Garden Reddiſh.

Raphanus niger rotundiore radice.
The rounder rooted blacke Reddiſh.

to *Napus*, calleth *viridis*: the *Corinthia* ſaith *Theophraſtus* is the greateſt, whoſe roote is bare above ground, growing upwards and not downewards as the reſt doe, *Liothalaſia* called of ſome *Thracia*, doth beſt indure the cold, *Bœotia* is ſweeteſt, the forme being ſmall and round, when as the *Cleonæa* is ſomewhat long. Now let any one referre all theſe ſorts rightly, to the kinds of Reddiſhes knowne to us, *& erit mihi magnus Apollo*. The *Italians* call it *Ramoracia*, the *French Grand raphaim* and *grend raifort*, the *Germans Merrettich*, (and thereupon *Tabermontanus* calleth it in Latine *Raphanus marinus*) and ſome *Krein* or *Kren*, the *Dutch Meerradys* and wee in *Engliſh* Horſe Reddiſh, Mountaine Reddiſh, and in the North greene Reddiſh, but better I thinke Clownes Muſtard for it is too ſtrong for any tender ſtomacke.

The Vertues.

Horſe Reddiſh is hot and drie in the third degree: with the roote ſalt and vinegar is made a Muſtard much uſed with country people, and ſtrong labouring men in ſome countries of *Germany*, &c. and in our owne land alſo, but as I ſaid it is too ſtrong for tender and gentle ſtomackes, for as *Matthiolus* ſaith, to thoſe that uſe it, it hurteth the head, and cauſeth ſharpe and ſoure belchings, but it is of much good uſe in the paines of the raines, bladder, and ſtone, provoking much urine and helping to ſeparate the gravell from the ſtone and to expell it, being boyled with hony and vinegar into an Electuary: it is alſo a good remedy in ſtrong bodies, both for the Cough, the Tiſſicke and other diſeaſes of the lunges, as alſo to procure womens courſes that are ſtopped: the ſame alſo by provoking vomiting and ſweating, is often given before the fit of the *quartane* ague to alter the courſe: the juyce given in drinke is held to be very affectuall for the ſcurvy: it killeth the wormes in children being drunke, as alſo being laid upon the belly: the roote bruiſed and laid to the place grieved with the Sciatica-gout, joynt-ach, or the hard ſwellings of the ſpleene and liver, doth wonderfully helpe them all: the diſtilled water of the herbe and rootes is more familiar to be taken with a little Sugar for all the purpoſes aforeſaid.

CHAP. XXV.

Rapiſtrum. Wilde Rape or Charlocke.

IN this Chapter I ſhall ſhew you the ſorts of wild Rape called Chadlocke or Charlocke with us, whereof there are more ſorts knowne at theſe times then formerly were to the ancient writers.

1. *Rapum ſylveſtre non bulboſum.* The wild Rape or Turnep.

The leaves hereof are very like the garden long Turnep, but growing thicker and more plentifully from the roote, and more crumpled and rough in handling, the roote is long and ſlender, in the reſt it differeth not from it.

2. *Rapiſtrum*

2. *Rapiſtrum aliud ſylveſtre non bulboſum.*
Another wilde Turnep.

This other ſort hath ſmaller leaves at the bottome not jagged, but thoſe that follow are larger and ſomewhat jagged and waved, the flowers are yellow and the ſeede flat, and of a whitiſh yellow colour in ſmall long pods ſomewhat ſharpe.

3. *Rapum ſylveſtre ſive Rapiſtrum arvorum.*
Wilde Charlocke.

This wilde Rape hath many long and broad rough leaves hairy and greene, lying upon the ground round about the roote, ſomewhat deepely gaſhed in on the edges and round pointed; from among which riſeth up one ſlender and hairy ſtalke ſeldome many, branched from the middle upwards into many parts, with divers leſſer leaves on them up to the toppes where ſtand divers yellow flowers of 4. or 5. leaves a peece after which follow ſomewhat long and rough pods, not very ſlender with divers round ſmall reddiſh browne ſeede therein like unto Muſtard ſeede but larger, as quicke and ſharpe in taſte but more bitter then it: the roote is long and white, and growing wooddy when it runneth up to ſtalke and periſheth after ſeedetime.

4. *Rapiſtrum alterum arvorum.*
Another wilde Charlocke.

This other wilde Charlock hath large leaves waved in but not cut or jagged as the former, the upper leaves being whole and ſmaller, the flowers hereof are pale yellow and the pods following are not more ſmooth, with a ſhew of diviſions in them, and is annuall alſo.

5. *Rapiſtrum album articulatum.*
White wilde Charlocke.

This Charlocke groweth up with fewer, ſmaller and rougher leaves in ſome little or nothing jagged in others more: the ſtalks are rougher and lower then the others, the flowers likewiſe grow not ſo many together, neither are ſo great or yel-

1. *Rapum ſylveſtre non bulboſum.*
The wilde Rape or Turnep.

2. *Rapiſtrum aliud ſylveſtre non bulboſum.*
Another wilde Turnep.

3. *Rapiſtrum arvorum.*
Wilde Carlocke.

low

4. *Rapistrum alterum arvorum.*
Another wilde Charlocke.

5. *Rapistrum album articulatum.*
White wilde Charlocke.

6. *Rapistrum monospermon.*
One grained Charlocke.

9. *Rapistrum maximum rotundifolium monospermon Hispanicum.*
Spanish one grained Charlocke.

yellow, but eyther pale yellow or more white, after which come ſmaller rough pods with joynts or diviſions in them, with ſmaller browniſh ſeede nothing ſo fiery hot as the other: the roote is ſmall and long in ſome, in others ſomewhat thick and rounder neare unto a ſmall long rooted Turnep. Of this kinde alſo ſome are found with a purpliſh flower.

Flore purpureo.

6. *Rapiſtrum album nigris lineis.* Charlocke of *Naples*.

The Neapolitane Charlocke hath the greene leaves next the ground like unto thoſe of the Garden Reddiſh, cut in or torne on the edges in the ſame manner but harder and rougher, the ribs on the under ſide being hard and rough, but thoſe that grow upwards on the ſtalkes which are two foote high, are leſſe divided, and thoſe up higher and next the flowers long and narrow, without any inciſure at all: the flowers are white with blackiſh veines in them, and the pods that follow are ſmall and long with ſmall ſeede in them, nothing ſo hot or ſharpe as the former: the roote is white and long, ſharper in taſte then the leaves, which are in a manner herby without ſharpeneſſe.

7. *Rapiſtrum parvum Maſſilienſe.* Charlocke of Marſelles.

This ſmall Charlocke groweth not above foure or five inches high, with ſmall rough leaves with few diviſions in them of an inch long, and dented about the edges, the flowers are ſmall and of a pale blew colour like unto the Sea Stocke gilloflower, the pods that follow are ſmall and long conteining ſmall ſeede within them, the roote is ſmall and white.

8. *Rapiſtrum monoſpermon.* One grained Charlocke.

The lower leaves of this Charlocke are ſomewhat large thicke and hairy, of a very freſh greene colour torne on both edges at the bottome, but broader at the ends where they are onely waved, the ſtalkes alſo are a little hairy about a foote high or more, ſet with a few ſuch leaves as the loweſt, but ſmaller and branching forth into long ſpikes of gold yellow flowers the length of ones hand, in whoſe places come ſmall round ſtriped heads or huskes with a ſmall point at the end, containing in every one of them but one ſeede from whence it tooke the name: the roote is long, and white, and ſomewhat fibrous.

9. *Rapiſtrum maximum rotundifolium monoſpermon Hiſpanicum.* *Spaniſh* one grained Charlock.

This *Spaniſh* kinde differeth from the former *French* or *Dutch* ſort ſet forth by *Bauhinus*, in that it groweth higher, with larger leaves divided into parts, the end peece great, round, and more hairy: the branches more, the flowers large and white in yellowiſh huskes without any threds in the middle: the ſeede alſo rounder and not pointed at the ends.

The Place.

The firſt is found wilde in ſundry places, but for the profit of the ſeede is ſowen in fields in divers countries of this Land: the ſecond I found going from *Shorditch* by *Bednall Greene* to *Hackney*, the third, fourth and fift are found as well in Corne fields as in the Paſtures, and in the borders and hedges of them, as alſo on ditch bankes, and untilled and waſte grounds: the ſixt is of *Naples*, the ſeventh of *Marſelles* in *France*, the eighth in divers places of *Germany* as well as at *Mompelier*, and the laſt in *Spaine*.

The Time.

They doe flower and ſeede the one or the other all the Sommer long.

The Names.

They are diverſly named by divers, for ſome would make them to be ſorts of *Eryſimum*, others of *Sinapi*, and others referre them to the *Lampſana* of *Dioſcorides*, but they tooke their name *Rapiſtrum a ſimilitudine Rapi foliorum* for the moſt part, and therefore ſome would name them all wilde Turneps. The firſt is the *Rapum ſylveſtre* of *Matthiolus*, *Lugdunenſis* and *Tabermontanus*, and *Rapum non bulboſum* of *Lobel*; the ſecond is not extant in any author before, the third and fourth are called *Rapiſtrum* by *Brunfelſius*, *Dodonæus* and *Geſner in hortis*, and *Rapiſtrum arvorum* by *Lobel*, *Matthiolus* calleth it *Lampſana*, and ſo doth *Anguilara*, *Geſner in hortis*, *Lonicerus*, *Lugdunenſis* and *Gerard* their figures declaring it, *Lugdunenſis* maketh it to be *Lampſana vera*, and *Tragus* maketh it his fourth *Sinapi agreſte*, *Fuchſius* and *Turner* call it *Irion*, *Camerarius* and *Caſtor Durantes Eryſimum*, and *Bauhinus Rapiſtrum flore luteo*: the fift is the third *Sinapi agreſte* of *Tragus*, *Lampſana* of *Turner* and *Cæſalpinus* who alſo calleth it *Radix ſylveſtris*, *Rapiſtrum flore albo Erucæ folijs* of *Lobel*, of *Gerard Rapiſtrum arvorum*, and yet his figure of *Raphanus ſylveſtris* is agreeable unto this rather then unto *Dittander*, for which he ſetteth it, the rootes chiefly declaring it which are not made to be ſmall and creeping, of *Tabermontanus Armoracia quibuſdam Rapiſtrum album*, and *Rapiſtrum purpureum*: and of *Bauhinus Rapiſtrum flore albo ſiliqua articulata*: the ſixt is called by *Columna Lampſana Apula Plinij & Dioſcoridis*, and by *Bauhinus Rapiſtrum flore albo lineis nigris depicto*, which in my title is *Rapiſtrum album nigris lineis*: the ſeventh *Bauhinus* onely hath ſet forth by the name of *Rapiſtrum floribus Leucoij marini*, but I have entituled it *Rapiſtrum parvum Maſſilienſe*: the eighth *Bauhinus* hath mentioned in his *Matthiolus*, *Phytopinax*, *Pinax* and *Prodromus* by the name of *Rapiſtrum monoſpermon*: the laſt is mentioned in *Cornutus* hiſtory of *Canada* plants: the *Germans* call it *Gutthedrick* and *Hederick*, the *Dutch Hedericke*, and we in *Engliſh* Charlocke, Chadlocke and Kedlocke.

The Vertues.

The ſeede of the Rapë that groweth naturally wilde is hotter then that which is manured and ſowen and more bitter alſo, whereof ſome doe make uſe in ſtead of Muſtard ſeede, or mingle it therewith, but the oyle preſſed out of the ſeedes is that Rape oyle that is uſed in Lampes, and therefore called Lampe oyle, and is much better for that purpoſe then the Traine oyle which is made of the Whale, which Rape oyle in divers Countries of *Germany*, and ours ſerveth to make Sope withall in the ſtead of Oyle Olive, as alſo to fry their Fiſh, &c. it is little uſed in Phyſicke, but is in a manner wholly ſpent for the uſes before ſayd, or to feede ſmall birds. The other Charlocks have as little uſe in medicines as the former, and therefore untill I can learne ſome properties I ſhall forbeare to ſet downe any unto you.

CHAP.

CHAP. XXVI.

Bunias ſive Napus ſylveſtris. The wilde Navew.

THe Navew differeth little from the Turnep either in leafe flower or ſeed that they are hardly known aſunder, of both which being garden herbes, whoſe rootes are to be eaten and therein chiefly to be diſtinguiſhed, I have ſpoken in my former booke; of the wilde kinde hereof I am to ſpeake in this Chapter, which differeth almoſt as little from his owne kinde of the Garden, as the Garden kinds themſeles doe: nnto whom I muſt adde one ſtranger not well knowne to many.

1. *Bunias ſive Napus ſylveſtris noſtras.* Our wilde Navew.

Whoſoever ſaith *Lobel* hath ſeene and knowne the manured Navew, may ſoone upon the ſight hereof ſay it is the wilde ſort of it, becauſe it is ſo like thereunto in the long ſmooth and not hairy leaves, more or deepelier jagged then the Garden kinde, the flowers alſo are yellow, and the ſeede in ſmall pods like it but more ſharpe hot and biting: the roote likewiſe is ſomewhat tuberous, round and long withall of the bigneſſe of ones thumbe or thereabouts, with fibres at the bottome.

1. *Bunias ſive Napus ſylveſtris.* Our wilde Navew.

2. *Napus ſylveſtris Cretica. Candy* wilde Navew.

The *Candy* wilde Navew hath divers rough leaves of the length of ones hand, ſomewhat like unto the leaves of the white flowred Charlocke, or the wilde hedge Muſtard, divided into eight or ten gaſhes on both ſides, and each of them dented about the edges, the ſtalk is white round & rough, divided into ſundry branches each of them ending in a ſharpe point: the flowers ſtand not at the toppes but on the ſides, at the joynts with the uppermoſt leaves whoſe colour is not expreſſed, but the cods that follow them are very ſlender and ſmall, about two inches long.

The Place.

The firſt is often found wilde by the hedges and wayes ſides, and upon ditch bankes likewiſe, and in clay grounds eſpecially, and ſeldome in any other: the other was ſent from *Candy*.

The Time.

Theſe doe flower about the ſame time that the Charlocks doe.

The Names.

As the manured Navew is called βουνιας *Bunias* in Greeke and *Napus* in Latine, ſo this wilde kinde is called βουνιας ἀγρια, *Bunias* or *Napus agreſtis* or *ſylveſtris* in Latine, *ſignificatione a tumente radicis figura deducta, ſed rapis hoc nomen magis competere videtur, quàm* γογγυλις: but *Galen* putteth no difference betweene *Buniadas* and *Gongylidas*, as indeede there is little but in the forme and greatneſſe of the roote and ſweeteneſſe alſo. *Pliny* hath much erred herein, for in his 20. Booke and fourth Chap. he ſaith, that the Greekes made two ſorts hereof, the one they called *Bunium* which it ſeemeth hee referred to the manured, and *Bunias* to the wilde ſort, which by the judgement of the learned cannot hold true, for that *Bunium* is a farre differing plant as I ſhewed you before, and *Dioſcorides* alſo declareth it plainely, entreating of *Bunias* in one place, and of *Bunium* in another. *Pliny* againe in *lib. 19. cap. 5.* maketh *quinque genera Naporum*, five kinds of Navewes miſtaking the Greeke word ῥαφανις miſtaking it to be *Napus*, for it is evident that hee taketh this diviſion from *Theophraſtus*, who *lib. 7. cap. 4.* maketh foure ſorts τῶν ῥαφανίδων, *Raphanorum* and not *Naporum*. There is a great controverſie among divers learned men, whether of the ſorts of *Bunias* or *Napus*, *ſativus* or *ſylveſtris*, the ſeede ſhould be taken that is appointed to be put into the *Theriaca Andromachi*, ſome following the Greeke verſes of the Father, wherein the compoſition is deſcribed and tranſlated into Latine verſes, extant in *Galens* Latine workes, who mentioneth the ſeede of *Bunias dulcis*, which all doe underſtand to be the manured kind, and which *Dioſcorides* commendeth (for hee mentioneth no wilde kind thereof) to bee good againſt venome and poiſon; and ſome followlowing *Andromachus* the ſonne, who in a continued ſtile or proſe in ſetting downe the ſaid receipt, ſaith, the ſeede of *Bunias ſylveſtris* which many of our moderne Phyſitions doe better allow of, becauſe they have more acrimony in them, whereby they are thought to be more vigorous then the tame kinde, which is more ſweete, even as the *Thlaſpi* that hath the more ſharpeneſſe in it is taken for that compoſition, and for Mithridate alſo, before that which is milder. *Galen* alſo *lib. 1. de Antidotis*, examining the ingredients into *Andromachus* Treakle ſaith, the ſeede of *Napus ſylveſtris* that commeth from *Candy* is to be taken in that place. The firſt is called by *Tragus Rapum ſylveſtre* which ſome might thinke did better appertaine unto the firſt wilde Turnep, but that in his deſcription thereof he maketh the leaves ſofter then the manured Turnep, and uſed to be eaten of the poore while they are young, and that the roote is tuberous which this rape is not. *Turner* calleth it *Napus agreſtis*, *Lugdunenſis* and *Dodonæus*, *Napus ſylveſtris* and ſo doth *Bauhinus*, *Lobel* calleth it *Bunias ſylveſtris*, and *Napus*, and *Caſalpinus Rapa ſylveſtris*. The other *Bauhinus* had it ſent him from *Honorius Bellus* in *Candy*, yet by the name of *Bunias*

ſylveſtris and called by the *Cretanes Scilobroubes*, the *Italians* call it *Navone ſaluatica* and *Napoſaluatico*, the *French Navette*, the *Germans* wilde *Steckruben*, the *Dutch* wilde *Steckrape*, and we in *Engliſh* wilde Navew.

The Vertues.

This wilde Navewe as it is hotter and drier, eſpecially the ſeede than the tame, ſo it is more effectuall to provoke urine and womans courſes, helpeth the crudities of the ſtomacke and torments of the bowells, and put into the decoction wherein Horehound is boyled and taken it helpeth the yellow jaundiſe: the ſame effect that *Dioſcorides* and others give unto the ſeede of the manured Navewe, which is to expell venome and poyſon, not ſuffering them to doe any harme; the ſame *Galen* it ſeemeth giveth to the wilde ſort brought from *Candy*, and whereas *Matthiolus* ſaith, that the ſeede of the garden ſort taken in a decoction of Maiden hare or Lentilles, doth not onely drive forth the venome and infection of the ſmall pockes, but of all other ſpotted or infectious fevers and diſeaſes, and alſo defendeth the heart and ſpirits from being infected with thoſe contagious and malicious vapours, ſo the ſeede of this wilde ſort is found to be as effectuall if not more forcible.

CHAP. XXVII.

Paſtoria burſa. Shepheardes purſe.

I Have yet two kindes of herbes to entreate of, that ſome referre to this Claſſis, which I therefore bring in the end, becauſe that in not pleaſing my ſelfe in ſo doing, I know not how I ſhall pleaſe others that are judicious, for I doe not finde either of them to have that acrimony in them that the reſt have, for elſe this might be referred to the kindes of *Thlaſpi*, it is in many other things ſo like them. Hereof there are many more ſorts knowne now than formerly have beene, of which I ſhall ſpeake in this Chapter, and of the other in the next.

1. *Burſa Paſtoris major vulgaris.* The greater common Shepheards purſe.

The common Shepheards purſe hath divers ſmall and long leaves, ſomewhat deepely cut in on both ſides into ſeverall parts of a pale greene colour, among which riſeth up a ſmall round ſtalke parted into ſome branches, having ſmaller and leſſe divided leaves on them to the toppes, where grow many white flowers one above another, after which follow flat whitiſh powches or ſeede veſſes, ſmall at the bottomes, broad at the heads and parted like the *Thlaſpi*, in each ſide whereof lieth a ſmall browniſh yellow ſeede: the roote is ſmall and white, and periſheth after ſeede time, there is no ſharpeneſſe, and but a very little heate either in herbe or ſeede of this; although ſome attribute thereunto a little acrimony, but is drying and aſtringent.

2. *Burſa paſtoris major foliis non ſinuatis.* Great Shepheards purſe with whole leaves.

This other great Shepheards purſe hath a ſmall root with ſome fibres thereat, from whence riſeth uſually but one ſmall ſtalke a ſpan long, branched into two or three parts, whoſe lower leaves are whole without diviſion, having long footſtalkes to them, and thoſe upon the ſtalke compaſſe them at the bottomes, the flowers are white and the ſeede veſſels flat like the former.

1. *Burſa paſtoris major vulgaris.*
Common Shepheards purſe.

3. *Burſa paſtoris minor.*
The ſmaller Shepheards purſe.

3. Burſa

3 *Burſa paſtoris minor.* Small Shepheards purſe.

This ſmall one is in all things like the firſt, but that it is leſſe in every part thereof. And there is alſo another ſmall one that is in all things like the ſecond, having no diviſion on the leaves. *Minor folio integro.*

4. *Burſa paſtoris Alpina hirſuta.* Hairy Mountaines Shepheards purſe.

This ſamll Shepheards purſe hath many ſmall leaves lying in a round compaſſe upon the ground ſoft and hoary or hairy, of the bigneſſe of Lentilles, ſlightly dented, and ſometimes not at all, matting or ſpreading many heads of leaves, and from thence many ſlender naked ſtalkes, bearing white flowers, and ſmall long and yellowiſh pouches, greater than the common, with ſmall reddiſh ſeede within them: the roote is ſmall and threddy.

The Place.

The greater and leſſer ſorts that have cut leaves are frequent in every place with us, but the other two with whole, I have not ſeene to grow wilde, but in *Germany*, *Mompelier*, and *Italy*, as *Bauhinus* and *Thalius* ſay.

The Time.

They flower and ſeede all the Summer long, yea ſo quicke ſome of them are, that they flower and ſeede twicē in every yeare.

The Names.

It hath no *Greeke* name, and all that have written hereof do call it in *Latine Burſa* or *pera paſtoris*, except *Geſner*, who calleth it *Thlaſpi fatuum & Caſtor Durantes Herba Cancri*, *Bauhinus* maketh particular relation both of the ſecond and the laſt: and *Thalius* of that ſmall one with whole leaves: the *Italians* call it after the *Latine* name *Borſa di paſtore*, the *French Tabouret & bourſe de bergier*, the *Germanes Sickelkraut*, and *Teſchelkraut*, the *Dutch Borſekens*, and we in *Engliſh* Shepheards purſe or pouch, and in the North, Picke purſe and Caſeweede.

The Vertues.

Some doe hold that Shepheards purſe is cold and binding, others finding a little heate upon the taſte of the flowers and ſeede, doe judge it not to be cold at all but drying and aſtringent, and by that onely quality worketh ſo powerfully in ſtaying all fluxes of bloud, either in inward or outward wounds, as alſo the fluxes or laskes of the bellie, the bloudy fluxe, and the abundance of womens courſes, or the piſſing of bloud, the juyce or the decoction of the herbe with ſome Plantane being drunke, or any other way taken: ſome doe hold that the greene herbe bruiſed and bound to the wreſts of the hands, and ſoles of the feete will helpe the yellow jaundiſe: the herbe bruiſed and laid pultis wiſe upon inflammations, Saint *Anthonies* fire, or the like repreſſeth them: the juyce dropped into mattering or running eares helpeth them: it cloſeth the lippes of greene wounds, and is of great effect being made into a ſalve for wounds in the head.

CHAP. XXVIII.

Myagrum. Gold of pleaſure.

THe other plant that I entend here to ſet forth, and therein alſo not pleaſing my ſelfe to bring them into this Claſſis is *Myagrum*, Gold of pleaſure, whereof there are more ſorts come to our knowledge in theſe dayes than formerly hath beene.

1. *Myagrum ſativum.* Garden gold of pleaſure.

This golden ſeeded plant riſeth up with one or more upright round ſtalkes about two foote high, ſet with ſundry long and ſomewhat narrow leaves, of a whitiſh greene colour, ſomewhat deepely dented about the edges, or deepely waved, cōpaſſing them at the bottome, ſpread from the middle upwards into ſundry branches, bearing at their tops very ſmall yellow flowers, where when they are fallen, come ſmall flat ſeede veſſells, with gold yellow coloured ſeede within them, ſomewhat long and ſmall, the roote is ſmall and long, periſhing ſtill after ſeede time.

2. *Myagrum ſylveſtre ſive Pſeudomyagrum.* Wild gold of pleaſure.

This plant that is much found among the fieldes of flaxe, ſpringeth up but with one round ſtalke, almoſt a yard high, ſet about with long and ſomewhat narrow leaves, reſembling thoſe of Woade, but longer and ſmaller pointed, broad at the bottome where they compaſſe the ſtalkes about with a point end ſticking out on each ſide, ſhooting forth many branches from the very bottome almoſt, at whoſe toppes come forth divers whitiſh flowers verie like unto thoſe of Flaxe, after which riſe round ſmall heades, with a ſmall point at the toppe, very like in faſhion unto the *Myagrum* with one ſeede therein, but theſe are full of ſmall yellowiſh ſeedes like unto Creſſes, but ſweete in taſte without any acrimony when it is dry, and exceeding bitter when it is freſh as the herbe being greene is alſo.

3. *Camelina ſive Myagrum alterum amarum. Engliſh* Wormeſeedē.

The *Engliſh* Wormeſeede groweth very like the laſt, with a taller upright ſtalke, branching toward the top, but thicker ſet with long and narrow greene leaves, ſomewhat like unto thoſe of the ſingle Wall-flowers, but ſmaller, and of a whiter greene colour, and very like unto the leaves of *Cluſius* his *Leuconium ſylveſtre*, that it is often miſtaken for it, but that the leaves of this are ſomewhat ſmaller and not of ſo freſh a greene colour, at the toppes of the ſtalkes and branches come forth many very ſmall pale yellow flowers made of foure leaves apeece, very like alſo unto thoſe of that *Leucoium*, but much ſmaller, even more than halfe, which afterwards give ſmall long cods, containing within them very pale coloured ſeede, bitter in taſte, the roote is ſmall and wooddy, periſhing every yeare after ſeede, but riſing againe of the ſhed ſeede.

4. *Myagrum fœtidum.* Stinking gold of pleaſure.

The ſtalkes of this *Myagrum* riſe to be about two foote high being rough, round, and greene, bearing rough pale greene leaves on them, ſet here and there one above another, being foure or five inches long, and one and a halfe broad, very lightly waved about the edges: at the tops of the branched ſtalkes ſtand divers ſmall pale yellow flowers upon long foote ſtalkes in a thicke tuft together, where unto ſucceede ſmall round huske containing ſmall ſeede: the leaves and flowers hereof, not onely bruiſed but growing, have ſomewhat a grievous or evill ſent.

5. *Myagrum monoſpermon majus.* The greater one grained gold of pleaſure.

The firſt leaves hereof that lie upon the ground are long and narrow, round pointed, and cut in on the odges like unto Succory leaves, with a white line in the middle of every one, and of a pale greene colour, but thoſe that

2. *Myagrum sylvestre seu Pseudomyagrum.*
Wilde gold of pleasure.

3. *Cameline sive Myagrum alterum amarum.*
English Wormeseede.

5. *Myagrum monospermon majus.*
The greater one-grained gold of pleasure.

7. *Myagro similis siliqua rotunda.*
Round podded like Myagrum.

grow upon the whitish bending hard stalke, which groweth to be a yard high or more, spreading branches from the bottome are little or nothing waved about, but compassing it at the joynts where they stand, the toppes whereof are stored with small yellowish flowers on a long branch one above another, after which come round hard and white heads, small at the bottome, and broader at the toppes with three corners and a small middle point sticking up in each, whereof is contained but one seede which is long and reddish whereof it tooke the name: the roote is white, long and wooddy perishing after the seede is ripe.

6. *Myagrum monospermon minus.* The lesser one grained *Myagrum.*

This lesser *Myagrum* hath much smaller leaves, the lowest whereof are two inches long and one broad, waved about the edges, standing upon foote stalkes, and of a pale greene colour, from whence rise one or two slender stalkes about a foote high, with a few very narrow leaves set on them, compassing them at the joynts: the flowers are small and white, standing at the toppes in a round tuft together, where afterwards grow small round heades with one kernell apeece within them: the roote is white and thready but perisheth in the like manner.

7. *Myagro similis siliqua rotunda.* Round podded like *Myagrum.*

This plant hath a stalke a cubit high, hairy, brittle, and spread into branches, whose bottome leaves are about sixe inches long, and one and a halfe broad, rough, hairy, and sappy, not dented at all about the edges, a little sharpe in taste with some clammineese also, but those that are set at the joynts of the branches, and compasse them about are nothing so great, and the higher they grow, smaller and narrower, the flowers stand spike fashion on small branches, being small and of a white colour, after which come small round rugged heads with a pricke at the toppe, every one on a small long footestalke, greene at the first, and blacke when it is ripe, with an oylie yellow kernell within them.

The Place.

The first groweth in some places of *Italy* wild, but yet both they and we doe sow it in gardens for pleasure, and in the fieldes for the seedes sake, whereout is pressed an oyle that serveth the poore for meate, and the rich for their Lamps: the second is frequent in *Germany* most usually in all their flaxe grounds, which being in stalke like it, but not of that use is accounted a weede and cast away, except of such as will save the seede to give to small birds, whereon they will feede when it is ripe, and growing upon the stalke most greedily: the third groweth in many places of our owne country, and being once brought into the garden, and there suffered to shed the seede, it will come up yearely againe of it selfe: the fourth groweth in the sandy grounds about *Balsill*: the fift on the *Euganean* hills by *Padoa*: the sixt not farre from *Mompelier*: and the last neare *Lunella* that is also hard by *Mompelier.*

The Time.

All these flower in the Summer moneths, and their seeede is ripe about *August.*

The Names.

It is called in Greeke μύαγρον *Myagrum* and μελάμπυρον also *Melampyrum* as *Dioscorides* saith, and some μυάγριον *Myagrium*, *Paulus Æginæta* hath two sorts of plants of an oily substance, μύωδες *quod impurum aut sordidum significat, cujusmodi est Melampyrum, &* μύαγρον *quod muscipulum sive muscarium significat, quæ insidentes sive præter volantes muscas glutine suo implicat.* Some (saith *Matthiolus*) take the first sort here set downe to be the true *Myagrũ* of *Dioscorides*, which, he saith, it cannot be because this hath the leaves of Rocket, but *Dioscorides* his should have the leaves of Madder. Others againe as he saith would have the second sort to be it, which he disaloweth also, because the leaves are liker Woade than Madder, and therefore calleth it *Pseudomyagrum*, yet by the judgement of the best is the true one. Some there be also that take them both to be but one plant: but *Bauhinus* misliketh of their judgement, because they are described to be so different both in leaves and flowers, and therefore hee judgeth them to be two distinct plants as they are indeede. *Dodonæus* setteth downe this first *Myagrum* to be that plant which the *Germans* call *Flachsdotteren*, and *Leyndotteren*, which *Tragus* saith is proper to the second. *Dodonæus* also taketh this to be that kinde of graine which both *Galen* in *primo de aliment. facultat.* and *Theophrastus*, *lib.* 8. 1. 3. *&c.* call *Erysimum*, which *Gaza* translateth *Trionum*, and is like unto *Sesamum*, as both he and *Pliny* say, but not the *Erysimum* of *Dioscorides*, although *Pliny* confoundeth them both together, as you may reade here a little before, in the Chapter of *Erysimum*, whereunto I agree, but not that the *Erysimum* of *Theophrastus* is our *Tragopyrum* Buckwheate, as some would have it, for thereunto it is utterly unlike, in that the seede of *Theophrastus* and *Pliny*, their *Erysimum* is oily, which that of Buckewheate is not, nor is fit to be used for Lampes, as you shall heare further, when I come to speake of Buckwheate. *Tragus* taketh it to be, although not the true *Sesamum* of *Egypt*, yet to be very like it, as *Pliny* & *Theophrastus* before him did, and calleth it *Sesamum Germanicum*, the oyle of whose seede is not onely like the true oyle of *Sesamum*, but is of divers, and may safely be used in the steede thereof both for meate and medecine, and therefore some have called it *Sesamum minus.* The first is that *Myagrum* that *Matthiolus* misliked in *Ruellius* and others, that they should so call it, and saith his country people did call it *Droda*, *Drodella*, and *Dorella* having leaves like Rocket as he saith, and therefore calleth it *Pseudomyagrum*: *Lobel* in *Adversarijs* calleth it *Myagrũ Germanis & Cameline Gallis*, and in his *Icones Cameline Myagrum*, the *French*, as *Ruellius* and *Dodonæus* say, call it *Camelinæ* and *Camelinum*; *Bauhinus* in his *Matthiolus* and *Pinax* calleth it *Myagrum sativum*, *Dodonæus Camelina sive Theophrasti Erysimum & Myagrion Dioscoridis*, and so it is indeede: the second is the *Linaria quinta* of *Tragus*, which he also calleth *Sesama*, and of the *Germans Flachsdotter. Cordus* upon *Dioscorides* saith, some pertinaciously insisted that it was the true *Sesamum* of *Dioscorides*, but he there disproveth them, and saith his people called it *Schwaden* (which *Gesner* in his note thereupon saith, that some did interpret to be *Leyndotter*) whose toppe branches with the seede resembled the *Juba* of *Milium*, *Gesner in hortis Germaniæ* sheweth, that neither *Schwaden* nor *Myagrum Dioscoridis* (thereby judging them to be two severall plants) are *Sesamum*: *Matthiolus* calleth it *Pseudomyagrum* with the leaves of Woade, and *Bauhinus* in his *Matthiolus* giveth a more exact figure of it than *Tragus* doth, yet in imitation of it: *Bauhinus* notwithstanding that he hath given the figure of both, and saith, as I said before, that they doe import two plants, yet in his *Pinax* hee confoundeth them as if they were but one, bringing in the authors both of the one and the other, as *Lugdunensis* and others under his title of *Myagrum sativum*: the third is the *Cameline Myagrum alterum Thlaspi effigie* of *Lobel*, the second *Myagrum* of *Tabermontanus*, and his third *Erysimum* also: *Gerard* hath two figures hereof which *Bauhinus* noteth, the one by the title of *Cameline*, and the other of *Eruca angustifolia*: *Tragus* calleth it *Viola lutea sylvestris*, for as I said in the description, it is very like to the *Leucoium sylvestre* of *Clusius*, and in my judgement is the

Thlaspi amarum of *Lugdunenſis*, as who ſo will well compare them ſhall finde: the fourth is *Bauhinus* his *Myagrum fœtidum*: the fift *Bauhinus* ſaith was ſent by the name of *Bricorrves*, and that *Alpinus* called it *Pſeudoiſatis* but calleth it himſelfe *Myagrum monoſpermon latifolium*: the ſixt he alſo calleth *Myagrum monoſpermon minus*: the laſt *Bauhinus* ſaith grew with his brother *Iohn Bauhinus* at Mount *Belgrade* by the name of a *Myagrum*, and therefore he calleth it *Myagro ſimilis ſiliqua rotunda*, but ſaith it was called a *Lepidium* at *Mompelier*, and that Doctor *Doldius* ſent it him from *Norimberge* by the name of *Thlaſpi*.

The Vertues.

The oylineſſe of the ſeede of *Myagrum* ſerveth as *Dioſcorides* ſaith, to make the skinne ſmooth that is rugged in any part of the body, and *Galen* ſaith that the ſeede being oyly hath an emplaſticke or clammy quality therein, *Pliny* ſaith and *Ruellius* as it ſhould ſeeme from him, that the oyle thereof helpeth the Vlcers of the mouth, if it be therewith annointed: the oyle of the ſeede is of much uſe in *Germany* and other places where they ſow many fields therewith, and is uſed as I ſaid both for the poore mens tables and rich mens Lampes, and ſerveth alſo with a lye made of aſhes to make Sope, for which purpoſes it is moſt uſed; the oyle thereof being as I ſaid ſo like unto the true oyle of *Seſamum* being hot and cauſing thirſt if it bee drunke as the true oyle of *Seſamum* doth, may ſafely be uſed in the ſtead thereof, and no doubt will performe the like effects or very neere that the true oyle will. The ſecond ſort is in qualitie very neare the former, and although the herbe as the ſeede alſo while it is greene, is ſo bitter that no creature will taſte thereof, yet when they are dry they looſe their bitterneſſe, and the ſeede eſpecially becommeth ſo ſweete as no other can bee more acceptable to ſmall birds as Linets, Finches and the like to feede upon: the third being called in many places Worme ſeede, and I thereupon calling it *Engliſh* Worme ſeede, but by *Gerard* Treakle Worme ſeede is much uſed by the countrey people where it groweth to kill the wormes in children, the ſeede being a little bruiſed and given in drinke or any other way. The other ſorts I have not knowne to be uſed to any purpoſe, either inward or outward for meate or medicine, and therefore let this ſuffice untill we can underſtand with what vertues they are endued to be related.

CHAP. XXIX.

Cepaceum genus. The ſharpe Onion rooted kindes.

Epe, Porrum, Allium, Onions, Leekes and Garlicke as under one kind, are to be referred unto this Claſſis, of many whereof I have amply entreated in my former booke, of which I ſhall ſay little here, but of ſome others not there ſpecified, namely of other ſundry ſorts of Garlicke, yet I thinke good to recite ſome of the names of the other, and give you ſome of their Figures.

Of Onions (comming very likely of the Latine *Vnio*, becauſe the roote is ſingle, not giving off-ſets or encreaſe as other bulbous rootes doe) there is the ordinary round white one, the flat and the long both ſharpe and ſweete, and the greater and leſſer red flat, ſome onely on the outſide, others red quite through: the Squill or Sea Onion, I have there ſhewed to be no Onion: Of the ordinary ſort of Leekes, there is a greater and a leſſer, called *Ampelopraſſum* the *French* or Vine Leeke, Cives called *Schænopraſſum* which are the ſmalleſt, and Scalions, accounted by ſome, to be of the kindes of Onions rather then Leekes, becauſe they are called *Cepæ Aſcalonicæ*, or *Aſcalonitides*, and may be the *Gethyum* of *Theophraſtus*, which ſome call *Gethyllis*, *Lobel* taketh it to be *Bulbus Setanius* of *Theophraſtus* and *Pliny*. Beſides theſe, *Lobel* mentioneth a wilde Leeke, without ſent or taſte, which is like the Garden kinde, but ſmaller.

Inodorum Syriacum.

And *Tabermontanus* one of *Syria* with large leaves.

Of the tame or Garden Garlik, as well as of the wilde, I have given the deſcriptions of divers, both *Allium Urſinum* Raniſous, and *Moly* of ſundry ſorts, as *Moly Indicum bulbiferum ſive Caucaſon. Moly Homericum vel Theophraſti. Moly Pannonicum bulbiferum* of two ſorts. *Moly Serpentinum. Moly caule & foliis triangularibus. Moly Narciſſinis foliis. Moly montannm latifolium luteo flore. Moly Pyrenæum purpureum. Moly latifolium purpureum Hiſpanicum. Moly purpureum Neapolitanum. Moly pyxidatum argenteum Hiſpanicum. Moly ſerotinum Coniferum. Moly Dioſcorideum & alterum Hiſpanicum*, and *Moly Moſchatum vel Zibettinum Monſpelienſe*: The reſt are here to follow.

Moly Indicum Lobelij.
Indian Moly.

1. *Allium ſylveſtre.*
Crow Garlicke.

The Crow or wilde Garlicke is of two ſorts, each of them hath ſundry narrow long leaves like graſſe, the one ſofter, and the other ſtiffer and harder, from among which riſe up one or two ſlender bare ſtalkes, bearing a tuft of purpliſh flowers, and blackiſh ſeede after them: the roote is long and round with three coates, or ſeverall peelings,

the

Moly Theophrasti sive Homeri.
The Great Moly of *Theophrastus* or *Homer.*

Moly Serpentinum.
Serpents Moly.

Ampeloprassum.
Vine Leekes.

1.2. *Allium sylvestre & Allium anguinum.*
Crow Garlike, and spotted or Snakelike Ramsons.

the outermoſt whereof is whitiſh in the one, with ſundry fibres under it, and reddiſh in the other and encreaſeth by the offſets, but is not parted into cloves as the garden Garlicke is, ſo ſtrong ſmelling of Garlicke that the milke of Kine that feede thereon will taſte thereof.

2. *Allium anguinum.* Spotted or Snakelike Ramſons.

This kinde of Ramſon hath ſomewhat broader leaves then the other Ramſon, ſomewhat like to Lilly Convally leaves but ſpotted oftentimes with blacke ſpots as the ſlender ſtalkes, are which beare many ſmall white flowers on the head: the roote is bulbous but longer then the other, covered with a browniſh outward skinne or coate, ſomewhat netted as it were like *Gladiolus*, with a tuft of fibres thereto; it is called by Herbariſts as *Cluſius* ſaith *Victorialis longa* becauſe the *Gladiolus* is called *rotunda*.

3. *Scorodopraſſum.* Great Turkey Garlicke.

This great Garlicke ſhooteth forth ſundry great long leaves much bigger then the ordinary Garlicke, and after divers yeares abiding a great long ſtalke three or foure foote high with ſome leſſer leaves thereon naked from the middle up to the toppe, where it beareth a large tuft of flowers encloſed at the firſt in a thinne skinne, of a paler colour then thoſe of *Homers Moly* or rather whitiſh, with three ſquare huskes and blacke ſeede in them like the reſt: the roote is great white and almoſt tranſparent at leaſt ſhining, and ſeldome giveth offſets for encreaſe. There is another with looſer ſcaly and yellower rootes, and narrower leaves.

Alterum.

4. *Scorodopraſſum alterum bulboſo & convoluto capite.*

Great Turkie Garlick with a bulbed and twining head.

This other great Garlicke groweth after the ſame manner but larger in each part: the ſtalke riſeth ſometimes halfe a yard higher, having at the toppe a large head of bulbes like to the *Indian Moly*, wrapped in a thinne skin, with a long point growing above it being ſmaller to the end, which bulbes in time breake that outer skinne and ſhew the bulbes to be at the firſt purpliſh, but growing whiter afterwards, having alſo ſome flowers among them: the head with the toppe of the ſtalke at the firſt doth winde or twine it ſelfe like a Snake or Serpent, which when the bulbes grow to ripeneſſe ſtandeth upright: the roote is as great and white as the laſt, and more ready to part into Cloves like the ordinary ſort of Garlicke: both of theſe doe ſmell ſomewhat leſſe ſtrong then Garlicke, partaking of Leekes, from whence roſe the Greeke name as *Dioſcorides* ſaith.

5. *Moly Pannonicum latifolium primum Cluſii.* *Cluſius* his firſt leafed *Hungarian Moly*.

This *Hungarian Moly* hath divers long and ſomewhat broad leaves riſing from a white round roote that hath ſundry ſmall bulbes growing thereto: the ſtalke riſeth two or three foote high with thoſe leaves thereon, but naked or bare from the middle to the top, where it beareth a round tuft of purpliſh flowers, after which commeth blackiſh ſeede in three ſquare huskes.

3. *Scorodopraſſum.*
Great Turkey Garlicke.

3. *Scorodopraſſum alterum Lobelij.*
Another ſort of great Turkey Garlick with narrower leaves.

Moly

4. *Scorodoprassium alterum convoluto capite.*
Great Turkey Garlicke with bulbed and twined heads.

5. *Moly montanum latifolium primum Clusij.*
Clusius his first broad leafed Hungarian Moly.

6. *Moly Pannonicum odorato flore.* Sweet smelling *Hungarian Moly.*

This sweete kinde is very like unto the last, but with lesser leaves and fewer stalkes bearing at the toppe a long tuft of pale coloured flowers upon longer footestalkes hanging downe their heads, of a pretty fine fresh sent which abideth not long, but quickly vanisheth, the three square heads that follow bring blackish seede somewhat like to those of Pinkes or Gilloflowers, the round roote hath some bulbes growing thereto.

7. *Moly montanum capite rotundo purpureo.* Purple round headed mountaine Moly.

This purple mountaine Moly hath a few long narrow greene leaves set on the stalke like unto the other, and a large tuft of delicate purple flowers on short footestalkes, never fully opening themselves, and smelling somewhat strong of Garlicke: the round white roote hath some bulbes thereat.

8. *Moly Africum umbella purpurascente.* Purplish headed Moly of *Africa.*

This *African* Moly hath sometimes but one stalke of halfe a yard high or thereabout, and sometimes two or three, with a few somewhat broad and long leaves, pointed at the ends, and a litttle hairy about the edges: the tuft of purplish flowers at the toppe consist of five leaves set on long footestalkes.

9. *Moly Italicum album caule triangulo.* The small *Italian* white Moly.

This little *Italian* Moly hath one or two long hollow leaves, somewhat broad likewise, and ending in a point: the stalke is three square, growing to be halfe a foote high, with sundry small white flowers at the toppes: the roote is small and round, of a shining purplish colour smelling like the rest of Garlicke: *Pona* in his *Italian Baldus* mentioneth this.

The Place and Time.

These sorts of bulbous are peculiar to divers countries as *Germany*, *Hungary*, *France*, *Spaine*, *Italy*, *Turkey* and our owne Land also, flowring in Summer and seeding after.

The Names.

The names of them all are sufficiently expressed in their titles, all authors that have written of them not much diversifying their names from those here set downe, and therefore I shall not neede further to insist upon them.

The Vertues.

Onions are flatulent or windy, yet doe they somewhat provoke the appetite encrease thirst and ease the belly and bowells, provoke urine and womens courses, helpe the biting of a mad Dog, and of other venemous creatures, to be used with a little Hony and Rue, and encrease Sperme, especially the seede: they also kill the Wormes in children if they drinke the water fasting wherein they have beene steeped all night: being roasted under the Embers, and eaten with Hony or Sugar and Oyle, they much conduce to helpe an inveterate Cough, by cutting the tough flegme and causing it the easier to bee expectorate: the juice being snuffed up into

the

the Noſtrills, purgeth the Head, and helpeth the Lethargie, yet the often eating of them is ſaid to procure paines in the Head: it hath beene held with divers country people a good preſervative againſt infection to eate Onions faſting with bread and ſalt, as alſo to make a great Onion hollow, filling the place with good Treakle, and after to roaſt it well under Embers, which after taking away of the moſt outermoſt skinnes thereof, being beaten together is a ſoveraigne ſalve for eyther Plague ſore, or any other putred Vlcer: the juice of Onions is good for ſcalding or burning by fire, water or Gunpouther, and uſed with Vineger taketh away all blemiſhes, ſpots, and markes in the skinne, and dropped into the eares eaſeth the paines and noyſe in them: applyed alſo with Figges beaten together helpeth to ripen and breake Impoſtumes and other ſores. Leekes are much about the ſame propertie that Onions be, yet not altogether ſo effectuall; they are a remedy againſt a Surfet of Moſhromes being baked under the Embers and taken, and helpeth the Piles boyled and applyed warme; to avoyd tautologie I referre you to what hath beene ſaid before of Onions. Garlicke the garden kinds as the beſt, and the other as meaner are hotter then Onions or Leekes, and is more effectuall to all the purpoſes aforeſaid, being anciently accounted the poore mans Treakle, for that it is a remedy for all diſeaſes or hurts; for beſides the properties whereunto Onions are conducible, it hath a ſpeciall qualitie to diſcuſſe the inconveniences by corrupt agues or minerall vapours, or by drinking corrupt and ſtinking waters as alſo by taking off Woolfes bane, Henbane, Hemlocke, or other poiſonfull or dangerous herbes: it is held good alſo in hydropick diſeaſes, the Iaundiſe, Falling ſickneſſe, Crampes, Convulſions, the Piles or hemorrhoides and other cold diſeaſes: but to alter the ſtrong ſent thereof and cauſe it to be leſſe offenſive, divers have ſet downe divers things, as ſome to eate Rue, or herbe Grace, ſome to eate a raw Beane after it, others to take of a Beete roote roaſted under the Embers and others ſay by eating a few Parſley leaves.

VMBEL-

VMBELLIFERÆ.

VMBELLIFEROVS PLANTS.

CLASSIS OCTAVA,

THE EIGHT TRIBE.

CHAP. I.

Ferula. Fennell giant.

IN this Classis I am to intreate of all the kindes and sorts of umbelliferous herbes, such I meane as are generally so called, for there are many other herbes that beare their flowers and seede or berries on the toppes of their stalkes in manner of an umbell as those doe, as you may observe through the whole passage of the Booke, which cannot properly belong hereunto. Now because there be many sorts of these herbes I thinke it fit to distribute them into three Rankes or Orders: the first shall be of those which beare fine leaves like *Ferula*: the next shall be of such as have fine and thinne cut leaves like Carrots or Parsley: and the last shall be of such as have broad leaves like *Panax* or *Angellica*, that so under these three rankes, I may comprehend the whole Family or Tribe, of these umbellifers; yet I must entreate you to beare with the passages of some of these, if for names sake I insert sometimes into one forme, such as might be placed in an other, the vicinitie of the names constraining that effect.

Of these *Ferulas* there are two or three sorts plainely to be discerned to be differing one from another as shall be shewed.

1. *Ferula tenuiore folio.* Fine leafed Fennell giant.

This fine leafed Fennell giant bringeth forth sundry large hollow fungous thicke branched stalkes, of very light fine thinne (for substance but thicke set) leaves together, and bushing more than the next, both greener, finer, and shorter than it also, placed out of order, sometimes two or three or foure leaves together, the bottome of the stalkes being as thicke as ones finger, but compassing one another with broad thinne hollowish skinnes, at the bottome, from among which riseth up a strong upright stalke eight or ten foote high, sometimes as bigge as a great cudgell, set with divers such fine leaves thereon, one above another, compassing the stalke at the bottome: out of the bosome whereof come forth severall small branches towards the toppes, the toppe also being divided into sundry parts, forming a large umbell of small yellow flowers, which turne into blackish flat seedes, but yellowish, as they have beene observed in the gumme, two alwayes joyned together by the little foote stalke, whereon they stand, as is usuall in all these umbelliferous plants; the two inner sides being somewhat hollow, and the outsides round with the longnesse: the roote groweth very great and never decaieth, branching forth many wayes of a blackish browne on the outside, and somewhat white within, yeelding a thicke juyce being broken in any part, which doth quickly condensate and grow into a yellowish gummie substance, not smelling any thing strong in our country, as I have often proved, and nothing so much as the Gum *Sagapenum*, which is supposed to be gathered from the roote of this plant.

2. *Ferula latiore folio.* The broader leafed Fennell giant.

This other Fennell giant groweth in the like manner in all things, and as high, or rather higher, whose branched stalkes of leaves are more sparsed or thinner set than the former; and the leaves themselves of a darker greene colour, bigger also and longer: the flowers are yellow, and the seede somewhat larger: the gummie juyce that issueth forth from the roote of this smelleth a little more, even with us, than the former, although nothing so strong as the *Galbanum*, which we have in our shops, and said to be taken from this plant in the hot countries and climates of *Africa*, &c.

3. *Ferulago seu Ferula minor.* Small Fennell giant.

This small sort groweth nothing so high as the former, but abideth much lower than the ordinary Fennell, having leaves nothing so great or branched, yet larger than those of Fennell, as the tufts at the toppes, which give smaller seede than either of the two former, but somewhat like them and blackish: the roote is much smaller and whiter than either of them, with but few fibres thereat.

The Place and *Time.*

They are all found growing as well in *Narbone* in *France* among the rockes that are torrefied with the Sunne all

1. *Ferula tenuiore folio.*
Fine leafed Fennell giant.

2. *Ferula latiore folio.*
The broader leafed Fennell giant.

all day, as in divers places of *Italy*, *Apulia* and *Florence*, and divers other places, but yeeldeth little gumme in *Europe* that I can here of by any: they flower in *Iune* and *Iuly*, and the seede is ripe in the beginning or end of *August*.

The Names.

The Greeke call it Νάρθηξ, and the least ναρθήκιον which *Gaza* translateth *Ferula* and *Ferulago*; the Greeke name signifying *Thyrsum*, *virgultum*, *bacillum*, as the *Latine* name is deduced *a feriendo quod illius scapi pedamenta fruticibus & senibus baculi & scipiones fuissent*: *Martiall* calleth them *Ferulas tristes*, because they were *Sceptra pædagogorum*, wherewith he smote the hands or heades of his truant Schollers. The first is the *Ferula* of *Matthiolus*, *Cordus*, *Lobel*, *Dodonæus*, and others, which *Cæsalpinus* calleth *Ferula mas*, as he doth the other *fœmina*: the second is called by *Lobel*, and others from him *Ferula galbanifera*; but *Bauhinus Ferulago*, who thinketh it to be the same that *Gesner* and *Camerarius* calleth *Ferulaga*; but I am in doubt he was therein deceived, for both those sorts, as I said, are every yeare the one as high as the other with me, but *Ferulago* which is my last, importeth a dimunitive, as *Dioscorides*, *Theophrastus*, and all others have called it, *humilis Ferula*, and so doe *Lugdunensis* and *Tabermontanus* call it *Ferulago*, *Narthecium Theophrasti*.

The Vertues.

At the first springing up every yeare of the *Ferula*, before the leaves breake forth, there riseth up from the roote a great yellowish head like to the yolke of an egge, which the Shepheards there gather and rost under the hot Embers, being first wrapped in double wet papers or cloathes, and after eate them with Pepper and Salt, and this is a meate not onely pleasant and delightfull unto them, but mightily provoketh Venery, as they say. *Dioscorides* writeth that the inner pith of the stalkes while they are greene, being drunke with wine, helpeth those that spit bloud, or bleede at the nose, and are stung by the Vipers: the seede being drunke doth ease the griping torments of the belly and the chollicke. *Pliny* saith that the stalkes being boiled are pleasing to the stomacke, and so taken with new wine or with honey, but if any doe eate many of them, they will cause the head-ach: the juyce saith he of *Ferula* being taken to the quantitie of a beane looseneth the belly, it doth helpe the falling sickneſſe, being taken at severall times of the Moone: the fresh juyce of the roote dropped into the eyes cleareth the dimneſſe of the sight. *Pliny* setteth downe this observation, that as *Ferula* is most deadly to Lampreyes, so it is a most acceptable foode to Asses, but a present poison to other cattell. *Galen* briefely sheweth the properties hereof in this manner: the seede, saith he, doth heate, and rarifie, the pith of the stalke is of a binding qualitie, whereby it helpeth the spitting of bloud, and those that are troubled with the chollicke. The gummes that issue from these plants are much better than the rest of the herbe; for *Sagapenum* is hot and drie in the third degree, which being dissolved into the juyce of Rue and taken, doth wonderfully helpe to breake the stone in the bladder, provoketh urine and womens courses, expelleth the dead child, and strengtheneth the weake sighted eyes: being dissolved in wine and taken doth much helpe the cough, and the distillations of thinne rheume called Catarrhes: being dissolved in oyle and applied, doth strengthen the members that are out of joynt, or the overstretched joynts, and

mightily

mightily openeth the obſtructions of the Mother: *Meſues* ſaith it purgeth tough flegme, and other clammy humours, and is helpefull to all the cold diſeaſes of the braine, breaſt, and lungs, the joynts, aches alſo be they never ſo far remote: taken in what manner ſoever, it doth wonderfully expell the water of the dropſie taken withyellow Myrabaſanes, it abateth the hardneſſe of the ſpleene, and expelleth the windineſſe thereof being drunke, and diſſolveth the nodes, knots, and hard tumours being diſſolved in Vinegar and the juyce of Capers, *Galbanum* doth more heate, draw, aud diſcuſſe humours than *Sagapen*, and is more powerfull and availeable for the breaſt and lungs, and for hardneſſe in breathing, for burſtings, cramps, and convulſions: it is more powerfull to reſiſt poyſons being taken in wine with myrrha, and eaſeth the riſings of the mother, the giddineſſe in the head, the paines in the ſides, and the falling ſickneſſe: a little of the gumme ſpread like a plaiſter will breake and draw any bile or hard ſore, being laid theron, eſpecially if a little Turpentine be put to it: it is alſo of great good uſe in many plaſters and ſalves, to helpe to warme thoſe places or joynts that are cold, to diſcuſſe the humours gathered to the places, and to bring to maturitie contumatious ſores, and to heale them afterwards. Becauſe I have ſaid that *Galbanum* and *Sagapenum* are gathered from the rootes of theſe *Ferula's*, and that I ſhall ſhew you in divers places hereafter, that other gummes are taken in like manner from other plants. I thinke it fitteſt to ſhew you the manner of drawing out, and gathering the gummes from the rootes of all ſorts of herbes which is in this manner. After that you have digged an hole on one ſide of the roote of any plant in manner of a ſmall trench, and the bottome and ſides cleared from looſe earth and ſtones, that they be not mixed with the gumme; wound or cut the roote on that ſide is open, or make an hole therein, that ſo the gumme iſſuing out, be not ſtopped by a ſmall orifice or cut, and ſo let the juyce or gumme diſtill forth of it owne accord, but this muſt be done in the hotteſt and drieſt time of the yeare, that no raine or moiſture take it for ſpoiling it, and to hrve the place or trench the clearer, it were neceſcary to lay ſome flat ſmooth ſtones, or the like in the bottome to keepe it the clearer; if the juyce or gumme come out in droppes and doe not runne together of it ſelfe it is accounted the better. Some alſo wound the lower part of the ſtalke, and take the juyce that commeth from thence, but that is nothing comparable to the other, this being called *Scaparius*, and the former *Radicarius ſuccus*.

CHAP. II.

Thapſia. Scortching Fennell.

ALthough there is but one true *Thapſia*, yet for the reſemblance of other plants ſo neare thereunto, *Cluſius* hath referred ſome unto it, and entitled them *Thapſia*, which *Lobel* and others have called by other names.

1. *Thapſia fœniculi folio.* The true Thapſia or ſcorching Fennell.

The true Thapſia hath a ſmaller and lower ſtalke than *Ferula*, with ſomewhat broader and ſhorter leaves then it alſo, and nothing ſo much winged or branched, the flowers are yellow that

1. *Thapſia fœniculi folio.*
The true Thapſia or ſcorching Fennell.

2. *Thapſia latifolia Hiſpanica.*
Spaniſh broad leafed Thapſia.

ſtand at the toppes in umbells, and the ſeede is more like unto *Siler montanum* than *Ferula* or *Thapſia*, but much greater than it, and leſſe than *Ferula* or *Thapſia*, the roote is of the thickneſſe of ones thumbe, browniſh on the outſide, and much whiter than *Ferula* within, with a thicke barke, and a ſlender tough pith, yeelding forth a yellowiſh milkie juyce, being broken, which being condenſate is ſomewhat gummie, but hard and drie: at the toppe of the roote there groweth a ſmall buſh of ſhort haires, whereby this plant is knowne from *Ferula*, which elſe would ſcarce be diſcerned: the taſte of the herbe is ſomewhat ſharpe and unpleaſant, but the roote much hotter and offenſive to the taſte and ſtomacke, moving vomite, and in the greene more than dry.

2. *Thapſia latifolia Hiſpanica.*
Spaniſh broad leafed Thapſia.

The leaves of this Thapſia are ſomewhat like unto Fennell giant, greene, but covered over with a little woolly hairineſſe, ſpread round about on the ground, of an unpleaſant taſte: the ſtalke that riſeth up among them, groweth to be a cubite, and ſometimes to be two cubits high, of a fingers thicknes, with a few joynts and leaves at them like the lower but leſſe, at the top whereof ſtand ſomewhat broad umbels of yellow flowers, which while the ſeed is in ripening changeth the forme to be round as a ball: the ſeede is broad & winged as it were, the middle part wherof which ſprouteth out the leaves is long and narrow: the roote is ſomewhat like the former, thicke, long, and broader at the toppe, with a blackiſh thicke barke full of a milkie juyce which is moſt bitter and ſharpe in taſte, provoking vomiting and white within.

3. *Thapſia maxima Hiſpanica.*
The greater *Spaniſh* Thapſia.

This Thapſia ſhooteth forth ſtalkes three or foure fingers thicke, like to a *Ferula*, and exceeding any mans height, having branched winged leaves like the laſt, but larger, and ſpread on the ground like it: the flowers and ſeedes are like it alſo: the roote is greater.

4. *Thapſia Carotæ folio.* Leafed Thapſia.

This was the moſt uſuall Thapſia that the ſhoppes of thoſe

4. *Thapſia vulgaris Carotæ effigie.*
Carrot leafed Thapſia.

Seminum Thapſiæ 5. genera cum folio & radice latifoliæ.
Five ſorts of Thapſia ſeedes, with a leafe and a roote of the broader leafed one.

Thapſiæ Carotæ folio ſummitates.
The toppes of the Charrot leafed Thapſia.

parts

parts of *Europe* knew, and tooke to be right, until learned and judicious men ſcanning it better, found it to be much differing, having large winged leaves lying upon the ground, more like unto the wilde or tame Carrot, than unto *Ferula*, whereunto the true is compared: the umbell of flowers is yellow, but ſmaller, as is both ſeede and roote than the *Ferula*: *Matthiolus* let this forth firſt for *Thapſia*, but is diſproved by all: it ſmelleth ſomewhat ſtrong.

5. *Thapſia fœtiſſima.* Stinking Thapſia.

In the country of *Salamanca* in *Spaine*, with *Cluſius*, groweth a certaine *Ferulous* plant with leaves like *Libanotis* herbe Francumſence ſpread upon the ground, bedewed alwayes with a clammie moiſture, of a deepe greene colour and ſhining: the ſtalk is ſaid to be ſmall and ſtraight, bearing an umbell of flower almoſt as round as a ball.

Wee have had the ſeedes of a *Thapſia* brought us out of *Spaine* by *Boel*, whoſe rootes were ſhort and tuberous, but the late ſpringing, and ſmall time of the abiding of them in my garden, by the early froſtes comming thereupon tooke them away ſo quickly that I can give you no further relation of them: but he called it *Thapſia tuberoſa radice*, which whether it were a ſpeciall kinde, or but the youngneſſe of the rootes I cannot tell, never having the like opportunity to get of the ſeede againe. *Thapſia beroſa radice.*

The Place and *Time.*

The firſt, as *Dioſcorides* ſaith, groweth in *Thapſia* one of the Iles of the *Sphorades*, and in the countie about *Athens*, as *Theophraſtus* ſaith, and as *Lobel* ſaith about *Mompelier*, and the way to *Frontignacke*; all the reſt grow plentifully in ſundry parts of *Spaine*, and doe flower there, as he ſaith ſomewhat late.

The Names.

It is called in Greeke θαψία, and *Thapſia* alſo in Latine, from the Iland of that name, as *Dioſcorides* ſaith; but as *Lobel* & *Pena* ſay, it may as well be ſo called from the fierie heate, wherewith it ſcorcheth or burneth the bare parts of the body, even a farre off, if they ſtand in the winde or breath of it that gather it; and therefore *Dioſcorides* adviſeth not to gather it, but in a quiet day free from winde, and to be on the leeſide thereof for feare of exulcerating the face and hands, &c. The firſt is the true *Thapſia* of *Lobel* and *Pena*, and *Lugdunenſis* ſo entituleth it; and the ſecond *Thapſia* of *Cluſius*: the ſecond is the firſt *Thapſia* of *Cluſius* which *Lobel* and others ſetting forth for *Seſeli Peloponenſe majus* is taxed by *Cluſius* for ſo doing, ſaying, that their ſo eaſie ſliding to errour, ariſeth from their want of due conſideration of all the parts thereof, and the ſight of the true plant, and onely led by weake conjectures upon the ſight of the figure, and as he ſaith, is called *Cumillo* by thoſe of *Murcia* in *Spaine*: the third is *Cluſius* his third *Thapſia*, which ſome, as he ſaith, would call *Cicutaria maxima Lobelij*, for which he blameth them likewiſe; the fourth is *Cluſius* his fourth alſo, which as he ſaith the *Spaniards* call *Tuero*: the laſt is that *Thapſia* that *Matthiolus Anguilara* and *Cæſalpinus*, becauſe it is moſt frequent in *Italy* tooke to be the right, but is ſince knowne to differ much from it: *Lobel* in his Obſervations, *pa.* 452. in the title over it, maketh ſome doubt whether this plant ſhould be not the *Sagapenifera Ferula*, for all do account theſe *Thapſias* to be kinds of *Ferula*, & ſo the *Italian* name which is *Ferulacoli* doth import as much; but as I ſhewed you in the Chapter before, that I have gathered ſome gum from the *Ferula* in my garden, that hath bin in ſhew as pure and good gumme *Sagapenum* as any we have in our ſhoppes, and therefore I doe not thinke any gumme *Sagapen* was ever taken from this or any other *Thapſia*: the *Arabians* call it *Iamtum* and *Dryx*; the *Italians Thaſſia*, and thoſe of *Naples Siciba*, and other parts *Ferulacoli*: the *Spaniards*, as *Cluſius* ſaith, call this *Canaheja* promiſcuouſly with *Ferula* and *Libanotis*, making no diſtinction betweene them: the *French* call it *Turbit blave*, and *gris* by others: the *High* and *Low Dutch* little knowing them, have ſcarſe given them any name, but as the Latine doth: *Gerard* calleth them ſtinking and deadly Carrots, which how fitly it agreeth with any of them, but that of *Matthiolus*, let others upon due conſideration judge: I have called the true *Thapſia* according to the nature, burning and ſcorching Fennell, which if any can alter and give a better, I ſhall be well content: the rootes of the firſt *Spaniſh* kinde are accounted for *Turbith* with them, but they differ much from the right, and therefore are called *Thapſia turbith.*

The Vertues.

Thapſia, or the ſcorching Fennell, as *Dioſcorides* ſaith purgeth choller ſtrongly both upwards & downwards; two ſcruples of the barke of the roote, as well as halfe a ſcruple of the juyce therof drunke with mede or honied water, and if more be taken it is dangerous; this manner of purging is fit for thoſe that are aſtmaticke, or ſhort winded, or are troubled with paines in their ſides and ſpitting of bloud, but ſaith *Lobel* this manner of purging thereby is quite left of, and that worthily in reſpect of the danger to the inward parts, for more harme oftentimes came thereby than helpe, by the grievous torments it uſed to ſtirre up: *Galen* briefely ſetteth downe the properties thereof in theſe words; *Thapſia* hath a ſharpe and ſtrong heating facultie joyned with ſome moiſture, and therefore it violently draweth from farre, and digeſteth what it draweth: bnt much time is required to effect this, for being full of much moiſture, it is the fault thereof to be quickly corrupted. Outwardly applied it hath moſt uſually better ſucceeded, for as *Pliny* reporteth, *Nero* by annointing his beaten face with the juyce hereof, and very equall Francumſence and Waxe mixed together at night, ſhewed the next day his face to be free and cleare, contrary to expectation, whereby it hath beene found to take away all blacke and blew ſpots, bruiſes, markes, and blemiſhes in the skinne whatſoever, yea the morphew, leprye, ſcabbes, ſcurfes, wheales, puſhes, or the like, yet caution muſt be uſed not to ſuffer it to lie too long on the place, that is not much longer than two houres, and then to be waſhed with ſalt or ſea water warmed: it is uſed likewiſe being diſſolved into an ointment with good effect to the ſides or breaſt for the griefes therein, or for the paines in the feete or joynts: it ſerveth alſo to gather againe the prepuce in whom it is naturall to want it, by raiſing a tumour, and after mollified and ſupplied with fat things, ſupplieth the part of a prepuce: it ſerveth likewiſe to cauſe haire to grow apace where the places wanted it, or were deprived thereof. The rootes of the ſecond and third, but of the laſt eſpecially in former times were gathered by impoſtors in *Italy* and *Spaine*, and dreſſed like *Turbith* that is pared and pithed, and ſo ſold in ſtead thereof, untill diligence add experience to know the right, and refuſe the falſe, had prevented the future deceit; and *Matthiolus* declaiming againſt *Fuchſius*, who tooke theſe rootes to be the true *Turbith* ſheweth it was ſo taken in *Germany*; but I have ſhewed you before in the Chapter of *Alipum*, the many errors of former times in taking the *Tithymalls Scamony* for the true *Turbith*: the old women Leeches of *Salamanca* in *Spaine*, ſaith *Cluſius*, uſe the rootes of the third or greateſt *Spaniſh* kinde of *Thapſia* to procure womens courſes,

and to purge the body which it doth with that violence both pward and downeward that they are often brought into great danger that take it.

CHAP. III.

Peucedanum. Sow-Fennel.

WEe have three ſorts of Sow-Fennell to offer to your conſideration in this Chapter.

1. *Peucedanum majus Italicum.* Great Sow-Fennell of *Italy*.

The great Sow-Fennell hath divers long branched ſtalkes of thin and ſomewhat long leaves, three for the moſt part joyned together at a place, among which riſeth a fluted ſtraight ſtalke, neare as bigge as Fennell with ſome joynts thereon, and leaves growing thereat, and towards the toppe ſome branches iſſuing from thence, likewiſe on the toppes of the ſtalke and branches ſtand divers tufts of yellow flowers where after grow ſomewhat flat thinne and yellowiſh ſeede twiſe as bigge as Fennell ſeede. The roote groweth great and deepe with many other parts and fibres about them, of a ſtrong ſent like hot brimſtone, and yeelding forth a yellowiſh milke or clammy juyce almoſt like a Gum.

2. *Peucedanum vulgare.* Common Sow-Fennell.

The common Sow-Fennell groweth in the ſame manner that the former and hath no other difference but that this is lower and ſmaller by a fourth part, and the ſmell thereof as ſtrong as the former.

3. *Peucedanum minus.* Small Sow-Fennell.

As the firſt Sow-Fennell was larger then the ſecond, ſo this is leſſe then it, having ſmaller and ſhorter leaves of a blewiſh greene colour, of a little bitter taſte but almoſt no ſmell, the ſtalke is ſlender and round, about halfe a yard high, parted into divers branches, whereon ſtand ſmall tufts of white flowers in an umbell, which are ſucceeded by thicke ſhort ſeede almoſt like to Parſley, but of an aſh colour, and bitter ſharpe taſte. the roote is of the bigneſſe of ones thumbe, ſometimes greater or leſſer, with a buſh of haires at the toppe, blackiſh or browniſh on the outſide, with a thicke barke of a pleaſant ſweet taſte at the firſt and afterward ſharpe.

The Place and Time.

The firſt groweth naturally in *Italy* in divers places: the ſecond in good plentie in the ſalt low Marſhes a little by Feverſham in *Kent*: the laſt was found on Saint *Vincents* Rocke by *Briſtow*, by *Lobel* as hee ſetteth it downe in his *Adverſaria pag.* 331. and in *Hungarie* and *Auſtria* by *Cluſius*. They all flower and ſeede in the end of Sommer, that is in *Iuly* and *Auguſt*.

The Names.

It is called in Greeke πευκέδανον and in Latine *Peucedanus* and *Peucedanum*, ſome take it of the pitchy ſent it

1. *Peucedani majoris Italicum ſumitat.*
The toppes of the *Italian* Sow-Fennell.

2. *Peucedanum vulgare.*
Common Sow-Fennell.

carrieth

carryeth, and others of the Pine tree whoſe leaves are like it. *Apuleius* calleth it *Pinaſtellum*: the firſt is the *Peucedanum* of *Matthiolus*, *Anguilara* and others, and *Peucedanum majus Italicum* by *Lobel* and *Lugdunenſis*: the ſecond is called by *Bauhinus Peucedanum Germanicum* and *Peucedanum* ſimply without any other addition by *Tragus*, *Fuchſius*, *Dodoneus* and others: it is called alſo *Fœniculum porcinum* but by *Tabermontanus Cauda porcina*: the laſt is called by *Lobel Peucedani facie perpuſilla planta*: it is called by *Cluſius Peucedanum Pannonicum* and is probable as *Cluſius* and *Bauhinus* ſay to be the ſecond Saxifrage of *Matthiolus*: the *Arabians* call it *Harbatum*, the *Italians Peucedano* and vulgarly *Finocchio porcino*, and by ſome alſo *Pinaſtello*, by the *Spaniards Fenicho del porco*: by the *French Fenouil de Pourceau*, by the *Germans* of ſome *Harſtrang*, but commonly *Sewfenchel* or *Schebelwurts*, of the *Dutch Verkens Venekell* and we in *Engliſh* Sow-Fennell, Hog-Fennell, Sulphurwort and Horſtrange.

The Vertues.

The juice of Sow-Fennell ſay *Dioſcorides* and *Galen* uſed with Vinegar and Roſewater, or the juice with a little Euphorbium put to the noſe, helpeth thoſe that are troubled with the Lethargie, the Phrenſie, the turning of the braine or diſſineſſe in the head, the Falling ſickneſſe, long and inveterate Headach, the Palſie, the Sciatica and the Crampe, and generally all the diſeaſes of the Nerves and Sinewes uſed with oyle and Vinegar: the juice diſſolved in wine or put into an Egge is good for the Cough or ſhortneſſe of breath, and for thoſe that are troubled with winde and tormenting paines in the body: it purgeth the belly gently and diſſolveth the winde and hardneſſe of the Spleene, it giveth eaſe to thoſe women that have ſore travaile in child birth, and eaſeth the paines both of the bladder and reines, and wombe alſo: a little of the juice diſſolved in wine and dropped into the eares eaſeth much of the paines in them, and put into an hollow tooth ceaſeth the paines thereof. The roote worketh to the like effect, but more ſlowly and leſſe, and is to be boyled in water and the decoction thereof drunke: the dryed powder of the roote being put into foule Vlcers of hard curation clenſeth them throughly, remooveth any ſplinters of broken bones or other things in the fleſh, & healeth them up perfectly, & likewiſe bringeth on old and inveterate ſores to cicatriſing: it is alſo put into ſuch ſalves as ſerve to heate and warme any place. the roote is hot in the ſecond degree and dry in the third, but the juice is ſtronger. *Pliny* recordeth the vertues hereof in divers places: the roote being drunke in wine with the ſeede of the Cypreſſe tree in powder eaſeth the ſtrangling of the mother, but ſome uſe to burne it and by the ſmell thereof give eaſe thereunto: the juice helpeth the burſtings of children and their Navells when they ſticke forth: the roote is of ſo great force in greene wounds and ſores, that it draweth out the quitture from the very bones.

CHAP. IIII.

Libanotis, Herbe Francumſence.

THere be divers ſorts of *Libanotides* as both the old and new Authors have recorded, ſome whereof beare broad leaves, others fine and like Fennell, of which I meane to entreat in this Chapter, and referre the other to the laſt order of theſe Vmbelliferous plants, which containe thoſe with broad leaves.

1. *Libanotis Ferulæ folio ſive Cachryfera ſive Cachrys vera.*

Fennell leafed herbe Francumſence.

This herbe Francumſence is a worthy, goodly, and rare plant, ſhooting forth divers buſhy great reddiſh ſtalkes of leaves of a freſh greene colour, being ſomewhat thicker and longer then thoſe of the *Ferula* but ſhorter then of *Pencedanum* Sow Fennell, yet often and in many places ſet three together, of a quicke aromatick ſent and taſte comming ſomewhat neare a Lemmon: from among theſe leaves riſeth up ſometimes but not every yeare with me a good bigge ſtalke, but neither ſo great nor halfe ſo high as the *Ferula*, and not much above a yard high, nor much higher then the ſtalkes with leaves, branched into very many ſundry parts, bearing yellow flowers which are ſucceeded by pretty good big whitiſh yellow ſeede, round and a little long withall, ſomewhat creſted on the outſide two joyned together as is uſuall in moſt ferulous plants, which maketh one ſide flat, the ſmall footeſtalke running betweene, and is ſayd to be cauſticke or burning; which cauſed the name *Cachrys* to be given to it: the root groweth deepe and ſpreadeth much and with many branches in the ground, bigger then a great Parſnep at the toppe, and white on the outſide as well as inſide, with a pith in the middle, but ſo brittle that one muſt handle it very tenderly if he doe not breake it, and yeeldeth forth a clammy pale juice, of ſo fine a ſharpe ſent that I compare it to the Lemmon, and endureth many yeares.

2. *Libanotis ferulæ folio & ſemine, ſive Panax Aſclepium Ferulæ facie Lobelij.*

Lobel his Eſculapius, Woundwort or Allheale.

Divers learned men have ſet forth each almoſt a ſundry herbe, for the *Panax Aſclepium* of *Dioſcorides* and *Theophraſtus*, and every one ſuppoſing his to be the right, and becauſe they all ſeeme to be worthy plants fit to be knowne, I thinke it meete to ſhew you them all with their differences, and wherein they come neareſt or are further off from the true, and firſt to beginne with that of *Lobel*, which groweth nothing ſo high or great as the *Ferula*, with fine leaves like unto it and yellow flowers alſo: but the ſeede that followeth is broad not ſo ſmall as Fennell but more like unto Ferula of a little quicke taſte or ſent: the roote is ſmall and not growing deepe, nor abideth after it hath given ſeede, the ſent and taſte being not much reſinous or ſharpe.

3. *Panax Aſclepium Matthioli. Matthiolus* his Eſculapius Allheale.

Although *Pena* being very ſpleneticke againſt *Matthiolus* in many things doth thinke and ſo doth *Columna* alſo that this *Pinax Aſclepium* is no other herbe then a *Ferula*, yet ſurely I thinke they are much miſtaken therein both for that *Matthiolus* had ſet forth the *Ferula* before and deſcribed it at large, and although he had not deſcribed his *Panax* as he did the *Ferula*, I preſume the chiefe cauſe was that hee had onely the dryed plant ſent him without a deſcription and therefore ſo let it paſſe, not intending to coyne a deſcription of that which hee never ſaw growing, as alſo becauſe *Bauhinus* doth number it among the other ſorts as a differing *ſpecies*, and *Lugdunenſis* giveth his Figure alſo which is divers from the *Ferula* in my opinion having finer, ſmal-

1. *Libanotis cachryfera ſive Cachrys vera.*
Fennell leafed herbe Francumfence.

2. *Panax Aſclepias Ferulæ folio Lobelij.*
Lobel his Eſculapius Woundwort or Allheale.

ler and ſhorter leaves then *Ferula*, and a ſmaller umbell of flowers, the roote likewiſe is ſmall and no way anſwerable to a *Ferula*.

4. *Panax Aſclepium Apulum Columnæ.*
Columna his Eſculapius Allheale of *Naples*.

Fabius Columna ſaith that this his *Panax Aſclepiũ* is thẽ trueſt of any other, hath bin deſcribed by any other author, growing frequently in *Apulia*, anſwering it in every part according to the deſcriptions thereof in *Dioſcorides* and *Theophraſtus*. Fo it hath a ſmall ſlender roote with a buſh of haires at the toppe of the bigneſſe of ones thumbe, with a thicke rugged barke of a whitiſh yellow colour on the outſide, and ſpungie white and wooddy pith within, full of a clammy white milke hardening quickly into a Gum which is bitter and ſharpe in taſte and unpleaſant but yet aromaticall: the ſtalkes of leaves which are ſpread next the ground, in a round forme at the head of the roote, are cut into ſeverall long haires as it were thicke ſet together, ſomewhat like unto common Yarrow and hairy withall, which is not ſeene in the other ſorts, or rather like unto Fennell leaves but bigger, having ſeven winged leaves ſet on a pretty big ſtalke, five bigger and two ſmaller which are next the hairy ſtalke, being greene at the firſt, but changing yellow when it groweth toward flowring, which with the leaves is halfe a yard long: frõ among theſe doth riſe up but one maine of ſtalke, which is ſlender two or three foot high ſometimes, having ſome joynts but no leaves thereon to the toppe, whereat uſually ſtand but one or two ſmall tufts or umbells of yellow flowers and ſeldome three, but ſpread a little largely and growing cloſer and rounder as it turneth to ſeede which are flat and winged on both ſides two growing togethẽr as is uſuall in all other umbelliferous plants, whereon as alſo on the ſtalke is often found a ſweete ſmelling Gum as cleare as Turpentine or Gum Arabecke, which is hardly diſſolved in water without heate, the like alſo is taken from the roote cut in peeces, but that it is yellower becauſe it muſt be forced by the fire.

4. *Panax Aſclepium Apulum Columnæ.*
Columna his Eſculapius Allheale of *Naples*.

5. *Panax*

5. *Panax Aſclepium Dalechampij.* The French Eſculapius Allheale.

The French kind *Dalechampius* found about *Mompelier* having a white roote like Parſly, ſlender, ſharpe and well ſmelling, and leaves alſo like Parſly, or rather like Coriander then Fennell and ſomewhat hairy with umbells of yellow flowers of an abſolute roundneſſe.

6. *Panax Aſclepium Anguilaræ & Camerarij.* Eſculapius Alheale of *Candy.*

This *Panax* which *Anguilara* and *Camerarius* have remembred, ſaying that in *Candy* it is uſually called *Seſeli* and in *Sicilia Peucedanum* though both falſely, riſeth up with a round Fennell-like ſtalke foure or five cubits high, with divers joynts thereon divided into branches of leaves, larger then Fennell and ſmaller then *Ferula*, of a darke greene colour on the upper ſide and of a blewiſh greene underneath, with large umbells of yellow flowers at the toppes turning into broad flat winged ſeede of a reſinous ſent and taſte, the leaves being much more milde, and yeelding a whitiſh milke nothing ſo hot or ſtrong in ſmell as *Ferula.*

7. *Libanotis minor umbella candida.* Small herbe Francumſence.

This ſmall herbe Francumſence hath ſundry leaves lying upon the ground, much cut and divided into longer parts than *Peucedanum*, and narrower than the greene *Engliſh* Saxifrage, the ſtalke hath but few joynts and leaves on them, bearing ſmall umbells of white flowers like *Meum*, and ſmall ſeede after them, almoſt like the ſeede of *Ammi*, Biſhops weede: the roote is great and white, divided into ſundry branches, and with a buſh of haires above.

8. *Libanotis ferulacea Germanica. Germane* herbe Francumſence.

The herbe Francumſence of *Germany* hath a blackiſh long roote, as thicke as ones finger, full of a reſinous juyce, ſharpe and well ſmelling, ſet with a buſh of haires at the toppe, from whence ſpring ſtalkes of fine Fennell-like leaves, but ſhorter than they: the ſtalke riſeth to halfe a yard height, on the toppes whereof ſtand bowing umbells of white flowers ſmelling ſweete. There is of this kinde a leſſer ſort alſo, not differing from the former in any thing, but in the ſmallneſſe.

The Place and *Time.*

All theſe kindes of *Libanotides* have beene found growing in ſundry places of *Italy* and *France*, except the ſixt, which as is ſaid hath beene found in *Sicily* and *Candy*, and the laſt in *Germany*, and doe all flower and ſeede, if the yeare be kindely, in the end of Summer.

The Names.

Λιβανωτὶς in Greeke is derived from Λίβανος, which is *Thus* or *Olibanum* Francumſence, bẽcauſe the ſmell of the herbes is compared to the ſmell thereof, and *Libanotis* likewiſe in Latine: but becauſe this later age hath found out divers herbes which may be referred for the forme, or for the ſmell, unto ſome of the ancients; *Theophraſtus*, *Dioſcorides*, and *Galen* (who yet in their writings, acknowledged that there are many more ſorts than they have ſet downe) I have here onely ſhewed you thoſe kindes that have fine leaves, whereof the Πάναξ Ἀσκλήπιον, or πάναξες ἀσκλήπιον may well be accounted as onẽ of them, both for forme and ſmell, taking the name from *Æſculapius*, who ended his life by a fall from of a ladder, as it is ſet downe by *Pliny.* The firſt is called *Libanotis ſeu Roſmarinum* by *Matthiolus* and others (and indeede many Writers have interpreted the *Libanotis* to be *Roſmarinum*, and thereby confound the two names together, for the λιβανωτὶς στεφανωματικὴ, *Libanotis Stephanomatice, id eſt Coronaria* onely is the fourth ſort of *Libanotis* with the ancients, which is properly the *Roſmarinum* of the *Latines*, and was, and is uſually put into Garlands, &c. and therefore ſo called *Coronarium*, when as none of the other *Libanotides*, being ferulous plants can fitly be called *Roſmarinum* in that ſence, or ſerve for that uſe) and is the firſt *Libanotis* of *Dioſcorides*, *Theophraſtus*, and *Galen*, whoſe ſeede is called *Cachrys* or *Canchrys*, as it is in ſome coppies, becauſe it is fiery in taſte. *Camerarius* calleth it *Libanotis cachryfera*, *Lobel Cachrys verior Libanotis Galeno*, and *Cæſalpinus Libanotis Candida.* This word *Canchrys* or *Cachrys*, is of divers ſignifications, and it is the pillot or ball wherewith they uſe to burne the skin to make an eſcarre, from whence alſo the ſeed had the name, having the like qualitie: and *Cachrys* is underſtood to be a ſcaly tuft (which ſome alſo take to be the catkins of ſundry trees) of leaves growing in Winter, and falling away, ſay ſome, in the Spring; but others thinke that it is but the germen or bud, which ſpreadeth into branches with leaves after Winter, when the Spring is come on: the ſecond hath his name in his title, as *Lobel* and *Bauhinus* call it, and is the *Panaces Aſclepium* of *Dodoneus* and others: the third is called *Panaces Aſclepium* by *Matthiolus*, *Lugdunenſis* and others, and by *Bauhinus Libanotidi ſecundæ ſimilis*, *Panax Aſclepium primum*: the fourth is ſo called by *Columna*, as it is in the title, and by *Bauhinus Panax ſemine folioſo*: the fift is the *Panax Aſclepium alterum* of *Dalechampius in Lugdunenſis*, which *Bauhinus* calleth *Panax Aſclepium umbella lutea*: the ſixt is the *Roſmarinum alterum ferulaceum Dioſcoridis* by *Lobel*, and by *Anguilara* and *Camerarius Panax Aſclepium*, for ſo it was entituled unto them by *Dodæneus*, and *Tabermontanus Libanotis ſecunda*, and by *Cæſalpinus Libanotis nigra*: the ſeventh is the *Libanotis Septentrionaliũ herbariorũ* of *Lobel*, and the *Libanotis minima* by *Lugdunenſis*: the laſt is called by *Thalius* in his *Harcynia ſylva Libanotis* ναρθηκιοειδὴς whereof he maketh a *major* and a *minor*, and I have thereupon called it *Libanotis ferulacea Germanica.* The *Arabians* call the *Libanotis Xaier Almarian*, *Aſpinalfach*, and *Calchala*, or *Cachola*: other Nations doe follow the erronious name of *Roſmarinum*, and theteafter call this as well as the *Latines Roſmarinum*, which is our ordinary Roſmary by one and the ſame name: but wee have more fitly diſtinguiſhed them, by calling this kinde, herbe Francumſence from the Greeke appellation.

The Vertues.

Dioſcarides ſaith that thẽ leaves of all the ſorts of herbe Francumſence doẽ uſually ſtay the bleedings of the *hemorrhodiall* veines, and eaſeth the heate, inflammations, and ſwelling of the fundament, if they be bruiſed and applied unto them, and doe digeſt the kernells and empoſtumations of the body, whereſoever they are hard to be cured: the dried rootes mixed with honey clenſe foule ulcers, and eaſe the paines and torments of the body or bowells, and being taken in wine helpeth the biting of venemous Serpents, and provoketh both urine and womens courſes: the ſame alſo helpeth to diſcuſſe ancient tumours or ſwellings being laid on them: the juyce of the herbe as well as the roote mixed with hony and annointed on the eyes quickneth the ſight, the ſeede being drunke doth the like, and helpeth thoſe that have the falling ſickneſſe, or have old paines in their breaſts or ſtomackes: it helpeth alſo the Kings evill, if it be taken with pepper in wine: it provoketh ſweat being put into oyle and annointed, it helpeth thoſe that are burſten, that have crampes or convulſions or the gout, if it be beaten

with

with the meale of darnell, and mixed with vinegar, and laid to the places: the ſame alſo mixed with ſharpe vinegar, cleanſeth the lepry, morphew, and the like deformities in the skinne: that ſeede that is burning, called *Cachrys*, is not to be uſed inwardly, for it is too ſharpe, and will exaſperate the throat: the greene roote is a great healer of all wounds being bruiſed and laid thereto, but ſaith *Dioſcorides*, the ſeede called *Cachrys* is of a heating and mightie drying qualitie, and therefore is good to be put into waſhing balls, or ſuch things as clenſe the skin, and being annointed on the head helpeth the defluxions and rheumes of the eyes, but it muſt be rubbed off the third day. *Eſculapius Panax* or Allheale, as the ſaid *Dioſcorides* ſaith, hath in the flowers and ſeede an helping power to heale ulcers, fretting or running cankers, and likewiſe wheales, puſhes, or the like breaking out in the skinne, being bruiſed with hony and applied to them; the ſame alſo is profitably both drunke in wine againſt venemous Serpents, as alſo to have the places annointed with it, and oyle mixed together.

CHAP. V.

Fœniculum. Fennell.

ALthough I have in my former booke given you the knowledge of two or three ſorts of Fennell, yet becauſe there are ſome others not there ſpoken of, I thinke it not amiſſe to ſhew you them all in this place together, and the rather, becauſe therein I did not ſo amply inſiſt on the vertues, as they did require.

1. *Fœniculum vulgare.* Common Fennell.

Common Fennell is well knowne to riſe up with ſundry round ſtiffe ſtalkes, foure or five foote high, bearing at ſeverall joynts long ſtalkes, of fine ſmall long leaves, ſmelling ſomewhat ſtrong, but not unpleaſant, and at the toppes on ſeverall branches, tufts, or umbells, of yellow flowers, which turne into ſmall round bitteriſh greeniſh ſeede, two alwayes together, as in the other umbellifers, and being ripe and drie become ſomewhat ſad coloured; the roote is long and white, running downe deepe into the ground with divers branches thereat: ſome doe make two ſorts, one with greene leaves wholly, an other with reddiſh greene leaves not differing in ought elſe.

2. *Fœniculum dulce.* Sweete Fennell.

Sweete Fennell groweth no otherwiſe than the former doth, having both rootes, leaves, ſtalkes, and flowers, after the ſame manner, ſaving that this, neither beyond ſea, nor in our country doth riſe ſo high, and hardly endureth the ſharpeneſſe of our Winters; the ſeede is larger, yellower, and ſweeter in taſte, neare unto Anniſeede then the former, which ſo continueth in the hot countries, but will not hold either colour, largeneſſe, or ſweetneſſe, long in our countrie, but each of them decay yearely, ſo that the third yeares ſowing, yeeldeth as bitter ſmall, and ſad coloured ſeede as any in any other garden or country of this land, ſo that you may hereby certainely know that it is the climate onely that changeth it to be either larger or ſmaller, longer or ſhorter, yellower or paler than others, & alſo giveth the taſte to be ſweeter or bitterer, which divers have thought to be differing ſorts: ſome alſo thinke that the Cardus Fennell, as the *Italians* call it, is a divers ſort of Fennell from the other ſweet ſort, when as it is onely the art in ordering it, by tranſplanting and whitening it that maketh the leaves grow ſo thicke buſhing together more than the ordinary, and the whiting giveth it a ſweeter relliſh, and a ſhorter criſpe taſte in eating.

3. *Fœniculum ſemine rotundo minore.* Small round Fennell.

There is a ſmall kinde of Fennell which differeth not from the common ſort, either in taſte or ſmell, but in being lower and ſmaller than it, and that the umbells at the heads of the ſtalkes are white, and the ſeede that followeth is leſſe than the ordinary ſort, being ſomewhat more like unto *Carum* Caraway ſeede.

4. *Fœniculum ſylveſtre.* Wild Fennell.

The wild Fennell groweth up with great, but fewer ſtalkes than the common of the garden, having alſo but few leaves, and thoſe very thinly ſet thereon, but ſomewhat ſtiffer or harder in handling, and ſhorter alſo; the ſeede is ſmall and ſomewhat round, which followeth after the ſmall umbells of yellow flowers.

5. *Hippomarathrum Creticum.* Great Fennell of *Candy*.

This great Fennell hath fine, but ſhorter leaves than the the ordinary ſort, the ſtalke is creſted and round, two or three cubits high, of the bigneſſe of ones finger, divided into ſundry branches, bearing yellow flowers at the toppes, and great large, almoſt round ſeede afterwards, the roote is great and whitiſh.

6. *Hippomarathrum ſphærocephalum.* Great round headed Fennell.

The ſtalkes of this Fennell are three cubits high, with large Fennell-like leaves, and round globe-like umbells,

1. *Fœniculum vulgare.* Crmmon Fennell.

whoſe

those flowers are of a purplish violet colour and large seedes like Fennell, but of a strong sent almost stinking: the roote is long and white enduring long: this is not the last called *Hippomarathrum Creticum* and *Cachrys ferum* for that hath yellow flowers and seede like *Cachrys*.

The Place and Time.

These sorts of Fennell grow in hot countries as in their titles and desciptions is declared, for the coldnesse of our climate altereth even the best and sweetest is sowen with us: the wilde sort was brought mee out of *Spaine* among other seeds by *Boel*: they an flower and seede in the end of Autumne if the yeare be kindly, I meane the strange sorts.

The Names.

It is called in Greeke μάραθρον, and *Fœniculum* in Latine, and both from one signification, *quod quasi fœnum in hyemes arefactum & marcidum reponatur, vel quod magno cum fœnore semen reddat, & cum inaruerit ad condienda multa plurimus sit usus*. The first is the most common both in our Land and both the *Germanies*, which they call *nostrum vulgare* as well as we, *Cæsalpinus* calleth it *sylvestre*, and *Camerarius in horto* saith that some tooke it to be *Hippomarathrum*: the second is the *Fœniculum dulce* of *Matthiolus* and divers others, and called *vulgare* by *Lugdunensis* which all *Germane* authors say doth as well alter in their countries as in ours, but holdeth more sweete still the hotter the countrey is wherein it groweth: the third *Bauhinus* onely hath made mention of in his *Pinax*: the fourth *Lobel* calleth *sponte virens in agris Narbonensium* and I may say as well *Hispanorum*, *Matthiolus* calleth it *Erraticum*, and *Anguilara* doubteth whether it may not bee *Hippomarathrum*: the fift is very probable to bee the *Hippomarathrum* of *Honorius Bellus* of *Candy* whereof he maketh mention in his first Epistle to *Clusius* which is extant in the end of *Clusius* his history of plants, who saith the *Candiots* call it *Platecumino*, whose seede as he there saith is as great as those of *Cachrys*, *Bauhinus* in his *Prodromus* seemeth to aime at this having but a branch thereof sent him out of *Signor Contarini* his Garden at *Venice*, but could not demonstrate the whole plant: the last is remembred by *Alpinus libro de exoticis*. The *Arabians* call it *Raienigi*, the *Italians Finocchio*, the *Spaniards Hinoio* and *Funcho*, the *French Fenouil*, the *Germans Fenchel*, the *Dutch Venkel*, and we Fennell.

The Vertues.

Fennell as *Galen* saith is hot in the third degree, and dry but in the first, and put to many uses, the leaves seede and rootes being both for meate and medicine, the *Italians* especially doe much delight in the use thereof, and therefore as I sayd before transplant it and whiten it, to make it the more tender to please the taste, which being sweete and somewhat hot and comforting the stomacke, helpeth to digest the crude flegmaticke qualitie of Fish, and other viscous meats which they much inure themselves unto. We use it to lay upon Fish or to boyle it therewith and with divers other things, as also the seede in bread or other things: the physicall use thereof is to breake winde to provoke Vrine and to ease the paines of the Stone and helpe to breake it: the leaves or seede boyled in Barley water and drunk is good for Nurses to encrease their milke, and to make it the more wholsome for their Nurse Children to take: the leaves being boyled in water but much more the seede stayeth the hickocke, and taketh away that loathing which often happeneth to the stomackes of sicke or feaverish persons, and alayeth the heate thereof, the seede boyled in wine is good for them that are bitten by Serpents or have eaten poysonfull herbes or mushromes, the seede and the rootes much more helpeth to open the obstructions of the Liver, Spleene and Gall and thereby much conduceth to all the diseases arising from them as the painfull and windie swellings of the Spleene and the yellow Iaundies: as also the Goute and Crampes, the seede is of good use in pectorall medicines, and those that helpe the shortnesse of breath, and wheesing by obstructions of the Lungs: it helpeth also to bring downe the courses and to clense the partes after delivery: the rootes are of most use in Physicke drinkes and brothes that are taken to clense the blood, to open obstructions of the Liver, and to provoke Vrine and to amend the evill colour or complexion in the face after long sickneſſe, and to cause a good colour and a good habit through the whole body: Fennell both leaves and seedes or rootes are much and often used in drinkes or brothes, for those that are growen fat to abate their unweldinesse and make them more gaunt and lanke: the distilled water of the whole herbe is likewise commended for the same purposes, as also to be dropped into the eyes to clense them from all enormities risen therein, but the condensate juice dissolved or as some take it, the naturall juice or Gum that issueth out thereof of it owne accord in hot countries, doth clense the eyes from mists and filmes that hinder the eye sight: some for this purpose take the greene stalkes of Fennell, and holding them to the fire in Autumne while they are greene, cause a certaine juice or liquor to drop from them, which they apply to the eyes, as holding it to bee more effectuall then eyther condensate juice or the naturall Gum. And some yet more neately make a water to cleare the eye sight in this manner: they powther some fine white Sugar Candy very finely, and put that powder into the hollow greene stalke of Fennell while it groweth a foote above the ground, so that it be betweene two joynts, which after it hath remained therein a day two or three, and the hole covered and bound close over that no raine get in in the meane time, they open it at the lower joynt, having first placed a good peece of soft wax made a little hollow gutture wise under the hole, which may serve as a gutter or quill to carry the liquor (from falling downe by the stalke) into a vessell or thing set of purpose thereto to receive it. The sweete Fennell by reason of the sweetnesse is much weaker then the ordinary, which is better to all the physicall purposes aforesayd, and therefore they doe but deceive themselves and others, that use the sweet Fennell seede in compositions as thinking it the better when as it is much the weaker, by want of the bitternesse which is the most operative: the juice of Fennell dropped into their eares that have wormes breeding in them, killeth the wormes: The wilde Fennell is stronger and hotter then the tame, and is therefore most powerfull against the Stone, but not effectuall to encrease milke, for it is dryer: *Honorius Bellus* saith that the women of *Candy* use to boyle the great seede of the *Hippomarathrum* of *Candy* in Lye to dye their haire yellow.

CHAP.

CHAP. VI.

Anethum. Dill.

ALthough formerly we have beene acquainted but with one ſort of Dill, and that *Theophraſtus* ſaith there are many ſorts but expreſſeth none of them, yet in theſe later times two other ſorts more have beene found out, which we will ſhew you together here.

1. *Anethum hortenſe ſive vulgare.* Common garden Dill.

The common Dill groweth up with ſeldome more then one ſtalke, neither ſo high nor ſo great uſually as Fennell being round and with fewer joynts thereon, whoſe leaves are ſadder and ſomewhat long, and ſo like Fennell that it deceiveth many, but harder in handling and ſomewhat thicker, of a ſtronger ſent alſo and unpleaſanter, the toppes of the ſtalkes have fewer branches and ſmaller umbells of yellow flowers, which turne into ſmall ſeede ſomewhat flatter and thinner then Fennell ſeede, and of a ſtronger and more unpleaſant taſte: the roote is ſmall and wooddy periſhing every yeare after it hath borne ſeede, and is unprofitable, never put to any uſe.

2. *Anethum ſylveſtre majus.* Great wilde Dill.

This great kinde differeth not from the former in any notable part but in the greatneſſe both of ſtalkes, leaves, flowers and ſeede and that it is found growing naturally wilde in *Sicilia* as *Cæſalpinus* ſaith.

3. *Anethum ſylveſtre minus.* Small wilde Dill.

As the laſt was greater in all parts then the firſt ſo this is much leſſe then it growing but a foot high, the leaves are fine and ſmall on the ſtalkes, and the flowers yellow like it, and the ſeede ſmall and long, thus in roote as well as the reſt being ſmaller maketh the difference, for both theſe laſt are but annuall as the firſt.

1. *Anethum hortenſe ſive vulgare.* Common garden Dill.

The Place and *Time.*

The firſt is moſt uſually ſowen in Gardens and grounds for the purpoſe, yet it is found wilde with us in ſome places: the ſecond as is ſayd hath beene found in *Sicilia* as the laſt, and ſent by *Columna* to *Bauhinus*, and by *Boel* from *Liſhbone* to us.

The Names.

It is called Ἄνηθον in Greeke παρὰ τὸ ἀνιδδεῖν *quod cito creſcat* ſay ſome, or as others thinke *quaſi* ἀνίκητον, *id eſt, invictum quia cibi appetentiam excitat*: as alſo ἀνηδεῖν *quod eſt congreſſus & coitio venerea ad quam laceſſit Anethi uſus ut antiqui prodiderant, tametſi plurimo uſu genituram tandem exhauriat.* The firſt is ſimply called *Anethum* by all authors, or *Anethum hortenſe* as *Bauhinus* doth: the ſecond is onely mentioned by *Ceſalpinus* and *Bauhinus* out of him, and the laſt by *Bauhinus* from *Columna*, and we from *Boel*: the *Arabians* call it *Zebet* or *Sebet*, the *Italians Aneto* the *Spaniards Eneldo*, the *French Anet*, the *Germans Dyllen* and *Hochkraut*, the *Dutch* alſo *Dille* and we Dill.

The Vertues.

Dill is hot in the third and dry in the ſecond degree, eſpecially being greene, but when it is dryed it is hot and dry in the third, digeſting then, more then before: it is good to breede milke ſaith *Dioſcorides*, but *Galen* in the Fennell before ſeemeth to gaineſay it, for being ſo dry it ſtayeth milke and engendreth it not, and to eaſe ſwellings and paines being boyled and drunke: the ſame alſo ſtayeth both the belly and the ſtomacke from caſting: the decoction thereof helpeth women that are troubled with the paines and windineſſe of the mother, if they ſit therein: it provoketh Vrine, it ſtayeth the hickock, being boyled in wine and but ſmelled unto tyed in a cloth, and dulleth the eye ſight, and being much taken extinguiſheth venery, for it mightily expelleth winde, and dryeth up naturall ſperme: the ſeede is of more uſe then the leaves, although they bee much uſed to relliſh condiments, and is more effectuall to digeſt raw and viſcous humors, yet more unpleaſant then Fennell, and is uſed in all medicines that ſerve to expell winde, and eaſe torments and paines thereof: the ſeede being toaſted or fryed and uſed in oyles or plaiſters, diſſolveth the Impoſtumes in the fundament, and dryeth up all moyſt Vlcers eſpecially in the ſecret parts: the oyle made of Dill is effectuall to warme, to reſolve humours and Impoſtumes whether ſoft or hard tumors, to eaſe paines and to procure reſt.

CHAP.

CHAP. VII.

Cuminum. Cumin.

CVmin is not knowne to moſt of our beſt latter writers and Herbariſts to be of any more ſorts then one; but wee have had the relation of other ſorts, but not thoſe of the ancients, as eyther *Syriacum*, *Ægyptium* or *Africum* which are but one and the ſame as many good Authors thinke, and but onely differing by the ſoyle and climate where they grew as ſhall be ſhewed.

1. *Cuminum vulgare.* Ordinary Cumin.

Ordinary Cumin groweth up with ſlender and low ſtalkes not above halfe a yard high, growing white at the laſt and brancheth out more, having ſtore of leaves which are ſmall and long like unto Fennell, the flowers are ſomewhat reddiſh at the tops of the ſtalkes, which turne into ſmall whitiſh yellow ſeed ſomewhat long and almoſt round, creſted or ſtraked on the rounder ſide and ſmelling ſtrong, the roote is ſmall long and white periſhing yearely.

1. *Cuminum vulgare.*
Ordinary Cumin.

2. *Cuminum Melitenſe dulce.* Small ſweete Cumin of *Malta.*

This ſmall Cumin whoſe ſeede is ſmall and like unto Anneſeede, but as ſweete as ſweete Fennell, is uſually ſowen in the Ile of *Malta* to put into their bread or other meates, as alſo to trade with to other parts, for exchange of other commodities, is as I am given to underſtand as ſmall and low a plant as the Cumin and much like it in leaves and growing, the ſeede onely is obſerved to be differing.

3. *Cuminum ſatiuum acre Melitenſe.* Great ſharpe Cumin of *Malta.*

This other hath greater ſeedes then the ordinary Cumin longer alſo and pointed at both ends, creſted likewiſe on the rounder ſide, and of a deader colour ſmelling more unſavourly and taſting hot quicke and ſharpe, almoſt like Cubebes or Pepper: and it is probable (for we never ſaw it greene) groweth greater then the ordinary, although like it in all other parts.

The Place and *Time.*

All theſe ſorts grow familiarly in the hot countries as *Spaine*, *Italy*, the Iles in the Mediterranean Sea, whereof *Malta* is one, and in *Syria*, and the other Eaſt countries where it is ſowen: in our Land it ſeldome commeth to good, unleſſe in a kindly yeare, and ſowen in the middle of the Spring, ſo that it muſt be late with us (though nothing ſo with them) before it can be ripe.

The Names.

It is called in Greeke κύμινον, and in Latine alſo *Cuminum* and *Cyminum*: the ancient authors as *Dioſcorides*, *Theophraſtus*, *&c.* made hereof many kinds, calling them by the ſundry countries where they grew, as *Egyptium*, *Galatium*, *Syriacum*, *&c.* when as it is confidently held they were not differing in *ſpecie* but in *loci prærogativa*, for although one ſort of ſeede was rough or hairy and white and called *Cuminum Æthiopicum* which *Hippocrates* called *Regium* as the beſt, another not rough or hairy called *Ægyptium*, yet they were not ſeverall ſorts but one was better than another according as the countrey gave it goodneſſe or excellencie. As for *Dioſcorides* his wilde kinds of Cumin, I have entreated of them before in the third Claſſis of this worke. The firſt is called by moſt writers *Cuminum ſativum* or *Cyminum*, yet *Cæſalpinus* taketh it to be *Cumini ſylveſtris primum genus Dioſcoridis*, *Guilandinus* calleth it *Cuminum Æthiopicum* and *Cordus* in *Dioſcor. Cyminum Romanum.* The two laſt are onely touched by *Bauhinus* in his *Pinax* and called by thoſe of *Malta Cuminagero* that is wilde Cumin and the ſweete kinde *Cuminagero dolce.* The *Arabians* call it *Camum* or *Kemum*, the *Italians Cumino*, the *Spaniards Cominohos*, the *French Comin*, the *Grmans Kimmell*, the *Dutch Comyn*, and we Cumin, and the ſeede Cuminſeede.

The Vertues.

The ſeede of Cumin is not onely moſt uſed with us who have little or none of the herbe growing, but every where elſe alſo, and both was and yet is in ſundry places uſed both in bread and meate to give a reliſh to them as we doe with Pepper, and was pleaſing as well to the ſtomack as the taſte: *Galen* ſaith it is in the third degree of heate, and in the ſame degree almoſt of dryneſſe, and as *Dioſcorides* ſaith, it heateth, bindeth and dryeth, but *Donæus* inſiſteth thereagainſt, ſhewing that Cumin ſeede by attenuating and digeſting doth diſcuſſe humors and doth not repreſſe them by binding or aſtruction, as in the ſwellings of the cods by winde or a wateriſh humor. Cuminſeede uſed in a Poultis doth quickly take it away, and ſo it doth all other paines and ſwellings, being boyled and Barley meale put unto it and ſo uſed: it alſo diſſolveth winde in the body and eaſeth the paines and torments thereof by the Collicke, being boyled in wine and drunke, and is is uſed as a corrector of any windy meats: in the ſame manner alſo taken it helpeth thoſe that are bitten by Serpents: the ſeede alſo taken in broth, or drinke or *Póſca* as *Dioſcorides* hath it, is good for thoſe that are ſhort winded, or are otherwiſe troubled with an old cough, or the diſeaſe of the breaſt to boyle the ſeede with Figges in wine: the ſame ſeede beaten and mixed with Vineger and applyed to the noſe that bleedeth doth ſtay the bleeding, and boyled in water and the lower parts bathed

thed therewith ſtayeth the abounding courſes of women: Cumin ſeede bruiſed and fryed with an hard Egge and bound to the backe part of the head eaſeth an old head-ach, and ſtayeth the rheume that falleth into the eyes or are blood ſhotten, or elſe the powder mixed with wax into the forme of a plaiſter and applyed warme to the eyes will ſoone helpe it, and take it away. Cumin ſeede is ſayd to make any one looke pale that uſeth it inwardly, or applyeth it outwardly.

CHAP. VIII.

Meum. Spignell.

OF *Meum* the ancients likewiſe knew and deſcribed but one kind, although it was entituled by divers names of the places where the beſt grew: but we have in theſe latter times beene acquainted with three or foure other plants which may not unfitly be referred alſo thereunto, as by their deſcriptions you ſhall ſoone uuderſtand.

1. *Meum vulgatius.* Common or ordinary Spignell.

The rootes of common Spignell doe ſpread much and deepe in the ground, many ſtrings or branches growing from one head which is hairy at the top of a blackiſh browne colour on the outſide and white within, ſmelling well, and of an aromaticke taſte, from whence riſe ſundry long ſtalkes of moſt fine cut leaves like haires, ſmaller then Dill, ſet thicke on both ſides of the ſtalke and of a good ſent: among theſe leaves riſe up round ſtiffe ſtalkes with few joynts and leaves at them, and at the toppes an umbell of fine pure white flowers at the edges, whereof ſometimes will be ſeene a ſhew of reddiſh or bluſh colour eſpecially before they bee full blowne and are ſucceeded by ſmall ſomewhat round ſeede bigger then the ordinary Fennell, and of a browner colour, divided into two parts and creſted on the backe as moſt of the umbelliferous ſeedes are.

2. *Meum aliud minus.* Small Spignell.

The ſmall Spignell hath a good big roote a foote long into the ground blacke on the outſide and white within without any branches downewards, but parted into ſeverall heads upwards, each whereof ſendeth forth ſundry ſhort ſlender ſtalkes of moſt fine ſhort leaves ſet by ſmall tufts together: among which riſe up a few low ſtalkes not above a foote high, bearing white umbells of flowers and very ſmall ſeede after them as ſmall as Parſley, but blacker of colour, the ſent whereof is moſt quicke ſharpe and very pleaſing as is the reſt of the plant.

3. *Meum Alexiterium Creticum.* The preſervative *Candy* Spignell.

The ſtalke hereof is about two foote high, as thicke as that of Dill and greene, with many long winged leaves thereon as finely cut as the former Spignell: the umbells of flowers are white and ſmall, and very ſmall long

1. *Meum vulgatius.*
Common or ordinary Spignell.

3. *Meum Alexiterium Creticum.*
The preſervative Spignell of *Candy*.

4. *Meum Spurium Italicum.*
Italian Baſtard Spignell.

5. *Meum Alpinum Germanicum illis Muttelina dictum.*
Mountaine Spignell of *Germany*.

ſweete ſmelling ſeede follow them: the roote is ſlender long and white of a fingers thickneſſe, ſmelling well and of a ſharpe taſte: Our author *Alpinus* ſaith hee had another ſort from the *Baſſan* hills, but this hee holdeth for the trueſt.

4. *Meum ſpurium Italicum.* *Italian* baſtard Spignell.

Baſtard Spignell is ſomewhat like unto the true, yet more like unto Dill with longer and thicker leaves: the ſtalkes riſe as high as the firſt with white umbells of flowers, and larger ſeede on them: the whole plant and every part whereof is of more ſtrong and unpleaſant ſent and taſte then the former, but the roote eſpecially which ſpreadeth branches like the true Spignell, but ſmaller ſomewhat like Sow or Hogge-Fennell.

5. *Meum Alpinum Germanicum illis Muttelina dictum.* Mountaine Spignell of *Germany*.

This Spignell hath but few ſtalkes of winged leaves riſing from the roote, ſomewhat broader then the leaves of the ordinary Spignell and ſhorter, and are betweene *Carum* and *Meum*; among which riſeth a ſlender ſtraked ſtalke a foote high bare of leaves for the moſt part to the toppe, where are ſet two or three ſmall umbells of purpliſh flowers each conſiſting of five ſmall leaves a peece, bearing ſeede afterwards that is ſomewhat long and reaſonable great, the roote is of a fingers length covered with a rugged blackiſh barke, and but few fibres adjoyning thereunto, and a buſh of haire at the toppe, of a ſmell ſomewhat ſharpe like the ordinary Spignell but much weaker.

The Place and *Time.*

The firſt groweth in many places wilde in the North countries of this Land, as in *Lancaſhire* and *Yorkeſhire* yet it is planted alſo in Gardens, the ſecond in *Savoy*, the third in *Candy*, the fourth in *Italy*, the laſt in *Auſtria*, and at the bottome of Saint *Vincents* Rocke by *Briſtow*, right againſt the hot water which is not to bee ſeene but at a low water as it hath beene affirmed to me by ſome: but I doubt it will prove *Lobel* his *Peucedani facie puſilla planta*: when it is better growne up with me I ſhall the better judge of it.

The Names.

It is called in Greeke μῶον and μεῖον, in Latine alſo *Meum*, and by ſome of the ancient authors *Athamanticum*, either from *Athamantes* the ſon of *Aeolus* who is thought firſt to have found it, or from the mountaine *Athamantes* which is in *Theſſalia* where the beſt grew: *Pliny* nameth it *Macedonicum* and *Hiſpanicum*, not as though they were ſeverall ſorts but as was uſuall with them in many other plants, they named the places where the beſt was gathered in their time: for the ſame *Pliny* ſaith that in his time *Meum* was onely ſowen in *Italy* by ſome few Phyſitions, when as it is now knowne to grow wilde in many places of *Italy*. The firſt is generally taken for the true *Meum* of the ancients, & ſo called by moſt of the moderne authors, yet *Tragus* and *Fuchſius* took it to be *Daucus Creticus* and *Cordus* in *Dioſcoridem* and *hiſtoria* to be *Tordylion*, ſome alſo called it *Anethum ſylveſtre*, & as *Ruellius* ſaith the *French Anethum tortuoſum*, and *Dodonæus* ſaith ſome tooke it to be *Libanotidis genus* and others *Faniculus porcinus*, *Fuchſius* calleth it *Seſeli Creticum*, and *Bauhinus* calleth it *Meum foliis Anethi*, becauſe he calleth the ſecond *Meum Dauci Cretici facie*, which *Lugdunenſis* calleth *Meum aliud*: the third is only remembred by *Alpinus*, & the fouth by *Matthiolus* that it is more like Dill then the firſt but not deſcribed, and therefore *Lobel* in his Obſervations

vations giveth a very briefe touch thereof, and the figure withall, calling it *Meum ſpinum alterum Italicum*. *Bauhinus* and *Tabermontanus* call it *Meum adulterinum*; the laſt is firſt remembred by *Geſner in hortis*, and then by *Camerarius*, who call it *Muttelina*, from the name *Mutry* or *Mutteren*, whereby the *Germanes*, *Helvetians*, and others did call it. *Bauhinus* in his *Matthiolus* and *Pinax*, calleth it *Meum Alpinum umbella purpuraſcente*, and maketh a doubt if it be not the *Daucus Montanus* of *Cluſius*, which in my mine opinion it cannot be, for that *Cluſius* ſaith, the leaves of that *Daucus* is like *Seſeli pratenſæ*, and the ſeede is as ſmall as Parſley, in both which this *Muttelina* differeth from it, although it ſeeme to agree in the purplish umbell, and ſomewhat in the roote: the *Arabians* call it *Me*, the *Italians Meo & Imperatrix* as *Matthiolus* ſaith, but that name is given by the vulgar *Italians* to *Angelica*, and many other plants that are of any eſpeciall vertue, as *Lobel* ſaith: the *Spaniards Finello*, and *Siſtre* of ſome, the *Freneh Meum*, the *Germans Beerwurtz*.

The Vertues.

Galen ſaith that the rootes of Spignell are hot in the third degree, and dry in the ſecond, whereby it is availeable to provoke urine and womens courſes, and the paines in the kidnies and bladder; but if more thereof be taken than is fit and convenient it cauſeth head-ach, for by ſending the hot vapours to the head, it is thereby moved and hurt; the rootes of *Meum* or Spignell (for no part elſe of the plant is of uſe unto us, and yet the ſeede is very aromaticall) boyled in wine or water and drunke, helpeth the ſtrangury, and ſtoppings of the urine, the winde, ſwellings and paines in the ſtomacke, the paines of the mother, and all joynt-aches: if the powder of the rootes be mixed with honey, and the ſame taken as a Lohoc or licking medicine it breaketh tough flegme, and drieth up the rheume that falleth on the lungs: the rootes are accounted very effectuall againſt the ſting or biting of any venemous creature, and is one of the ingredients into *Mithridatum* and *Theriaca Andromachi*, which are eſpeciall antidotes for the ſame, and many other effectuall purpoſes.

CHAP. IX.

Gingidium. Strange Chervill.

I Have two ſorts of this Chervill that properly belong to this Diviſion or Order, and there are two more which might be referred to the other Diviſions of theſe umbelliferous plants which I diſtinguiſhed in the beginning, yet for the names ſake, I would not willingly exclude them the family, but let them keepe company with the reſt at this time.

1. *Gingidium verum ſive Syriacum.* The true *Gingidium* or ſtrange Chervill.

The true *Gingidium* that *Rauwolfius* ſaw in *Syria* groweth up with an upright ſtalke ſomewhat rough, branching forth from the very ground almoſt, whereon are ſet ſundry ſtalkes of fine cut leaves, ſmaller than Fennell, eſpecially thoſe on the ſtalkes and branches, for the loweſt are a little broa-

Viſnaga Gingidium appellatum.

4. *Gingidium latifolium Syriacum.*
Broad leafed Chervill of *Siria*.

der

der; at the toppes where of grow great broad umbells of white flowers, a little purplish in the middle, which umbells before they flower hang downe their heads, and after the flowers are past, the umbells doe contract or draw themselves rounder, the outer part being higher than the middle, which then is so hollow, that it representeth a birds neast, somewhat like to the umbell of seede in the wilde Carrot, and beareth plenty of very small seed, the roote is not great, but long, white, and woolly, perishing every yeare that it beareth seede, which is usually the same yeare it is sowen, or else springing late and not shooting up in stalkes for seede, it will abide a Winter: the whole plant hath a little resinous taste and smell to my senses.

2. *Gingidium Hispanicum. Spanish* Toothpicke Chervill.

The *Spanish* Toothpicke Chervill groweth rather greater than the former, but with smaller and slenderer stalkes and tenderer leaves at the joynts, thicker and more finely cut at the toppes, whereat stand large umbells of white flowers, divided into many parts, and standing upon long stalkes, which when the seepe groweth ripe waxe hard, being long and slender, and serve well for tooth pickes: the roote is long and white: the whole plant is of a bitter taste.

3. *Gingidium Chærefolij foliis.* Another strange Chervill.

This other strange Chervill hath divers stalkes of winged leaves, very like unto the ordinary Chervill, but not divided into so many parts, the stalke is round, straked, and blackish, halfe a yard high, with joynts and leaves like the others: the umbells of white flowers are compassed about with smaller and finer cut leaves, which when the flowers are past are contracted together somewhat like the first, and are somewhat clammy, wherein lie small seede: the roote is long, white, and bitterish.

4. *Gingidium latifolium Syriacum.* Broad leafed Chervill of *Syria*.

This *Syrian* Chervill hath but few stalkes of winged leaves, somewhat like to Parsneps, but that every divided leafe is broad and round but lesser, the stalke is somewhat hairy, crested, small, low and naked of leaves to the toppe, where grow divers long stalkes with small umbells of white flowers, and two or three small long leaves with them: the smell and taste is like unto the first.

The Place and *Time.*

All these here expreſt, are said to be brought out of *Syria*, but the second groweth also plentifully in *Spaine*, from whench it hath beene brought and sent to friends: they all flower late, and therefore the seede is much later, so that if the yeare be not hot and kindly, the seede will hardly ripen with us.

The Names.

It is called in Greeke πλάδιον, and *Gingidium* in Latine; *Dioscorides* saith it was also called in his time *Lepidium*, but that name doth more fitly sute to another plant, as is shewed before: the old *Romanes* were wont to call it *Bisacuta*, and the *Syrians Visnaga*. The first, as I said, *Rauwolfius* in these later times first made knowne to the Christian world, having gathered it in *Syria*, giving it the name of *Gingidium Dioscoridis*, which it doth most truly represent, for *Dioscorides*, cõpareth *Gingidiũ* to *Pastinaca sylvestris*, which as it is finer in leafe, so is it most like in the head of seede, and *Camerarius in hortis* thereupon calleth it *Syriacum*: the second is the *Visnaga* of *Matthiolus*, *Lobel*, and others; yet *Matthiolus* would faine have it to be *Pastinaca sylvestris major*, because it groweth so great, *Tragus* calleth it *Seseli*, and *Fuchsius Seseli Massilienſe*, *Cæsalpinus Cumini sativi alterum genus*: the third is the *Gingidium* of *Matthiolus*, *Lugdunensis*, and *Tabermontanus*: the last is called by *Lobel Gingidium folio Baucia Syriacum*, and is the first *Gingidium* by *Dodonæus*; yet as he sheweth in the Chapter of *Pastinaca latifolia*, *Iacobus Manlius* taketh *Baucia* to be the *Pastinaca tenuifolia* of *Dioscorides*.

The Vertues.

These herbes are more used as nutriment than medicine, both in former times and now also where they grow, for *Dioscorides* and *Galen* speake more of the edible propertie, that they are by their bitternesse welcome and agreable to the stomacke, being eaten raw or boyled, or divers other wayes ordered, as those times and mens wills led them to take them: but in that *Galen* saith in one place, that they are rather medicinable than nourishing, it is because he sheweth that they have a temperate qualitie betweene heat and cold, but have a manifest bitter and binding property, by both which they are so commodious to the stomacke, that they are of the nature of a medicine, to clense and dry up the moist humours that by their abounding doe much offend the stomacke, and by it the liver and other parts: the other medicinable qualities also therein rising from thence, are to be profitable for the diseases of the bladder, and to provoke urine being boiled in wine and drunke.

CHAP. X.

Pyrethrum umbelliferum. The true Pelletory of *Spaine*.

THere are in mine opinion two sorts of this *Pyrethrum*, the formeof their leaves being different, inducing me so to thinke, although there be nothing else as shall be shewed.

1. *Pyrethrum umbelliferum primum.* The first Pelletory of *Spaine*.

This *Pyrethrum* hath divers stalkes of fine cut leaves, the forme and divisions whereof doe somewhat resemble the forme of Mayweede, being short, and not long like Fennell, or like wilde Carrots, as *Dioscorides* compareth them, from among which riseth up some stalkes, with few or no leaves on them, branched into two or three parts, bearing a round umbell of white flowers, after which follow somewhat round darke coloured seed bigger than Anniseede: the roote groweth sometimes as great as two thummes together, but often of a thumbes bignesse, and a foote or more deepe, of a brownish yellow colour on the out side, and whitish within, of a very sharpe and heating taste, drawing forth water into the mouth, more plentifully and quickly than the common Pelletory of *Spaine*, which hath a Daisie-like flower (as my taste if it deceive mee not, hath enformed me) howsoever some authors have set downe the contrary, and endured after seede timẽ, if it be somewhat carefully defended in the Winter time.

2. *Pyrethrum umbelliferum alterum.*
The other Pelletory of *Spaine.*

This other Pelletory groweth somewhat lower, the leaves are somewhat longer and finer, resembling Dill; the stalkes are slenderer and full of leaves, the umbells of flowers are white, but not so great: the roote is slenderer and single, and herein consisteth the chiefest difference.

The Place and *Time.*

The first groweth more usually in the hotter countries, of *Italy*, *Spaine*, &c. the other on some mountaines in *Germany*, and often among the rockes whereon there is but a crust of earth, so that the rootes grow in the chinkes: they flower and seede toward the end of Summer.

The Names.

It is called in Greeke πύρεθρον, *ob radicis igneum fervorem*, and *Pyrethrum* in Latine, as also *Salivaris*, from the quality to draw spittle into the mouth: the first is the *Pyrethrum verum* of *Matthiolus*, and *alterum* of *Lobel* and others, *Camerarius* calleth it *Pyrethrum Dioscoridis*, *Cæsalpinus* doubted to call it *Pyrethrum*, for untill it was well examined by the learned, they were loath to admit it as *Dodonæus*, who would rather find a fault in the description of *Dioscorides*, and suppose it to be a kinde of Saxifrage, than admit it for true *Pyrethrum*. The other is called by *Lugdunensis Pyrethrum Gesneri*, because *Gesner* sent it to *Dalechampius*, and as I said, is most probable to be a differing sort from the former; for I rather thinke this to be it that *Tragus* found on the mountaines, and called *Fæniculum montanum*, than the former, as *Bauhinus* doth, who also noteth it in his *Pinax*, that the *Pyrethrum*, that hee saw in the *Padoa* garden, varied in having yellow flowers from this, which hath growne with us and is white.

1. *Pyrethrum umbelliferum primum.*
The first Pelletory of *Spaine.*

The Vertues.

This Pelletory is hot and drie in the third degree: the roote taken with hony is effectuall against all cold diseases of the braine, as the Apoplexie, falling sicknes, the *vertigo*, or turning of the braine, and others of the like nature: it helpeth also the defluxions of rheume from the head to the teeth, being bruised and heated in some vineger, and the mouth gargled therewith, or the roote it selfe chewed in the mouth, doth often ease the furious paines of the tooth-ach if it proceede from rheume; it is effectually put also into all those oyles or oyntments that are used to warme and heate any part of the body, or the sinewes that are benummed with cold, or the dead or shaking palsie: for which purpose, some doe much commend an oyle drawne from the greene rootes, to be anointed, yea though the parts be drawing to a *gangrene*: assuredly, it much helpeth all cold griefes either inward or outward.

CHAP. XI.

Nucula terrestris, sive Bulbocastanum. Earth Chesnut.

OF the Earth Chesnut there is two sorts, a greater and a lesser in each part.

1. *Nucula terrestris major.* The greater Earth Chesnut.

The great plant bringeth forth divers long stalkes of leaves immediatly from the roote which are finely cut in and divided, somewhat like unto the leaves of Parsly, that grow on the middle or top of the stalke, as *Dodonæus* compareth them, yet larger than the next or small Earth-nut, among which riseth up a slender stalke about a foote high, bearing at the toppes many small white flowers in an umbell, which turne into blackish small long seede, smelling somewhat sweet: the roote is not fully round or smooth, but bunching out in one place or other, and somewhat rough, of a blackish browne colour on the outside, and white within, of a pleasant taste, betweene a Chesnut and a Parsnippe, which is often eaten by women and children, as they have roasted them by the fire or under the embers.

2. *Nucula terrestris minor.* The lesser Earth-nut or Chesnut.

This smaller Earth-nut hath a small roundish browne roote like the former, but lesser, from whence riseth up a long slender whitish string or stalke, whethersoever you will call it, within the ground, not alwayes rising straight up from the roote, which groweth foure or five inches deepe in the earth, but foulding or crumpling it selfe to and fro unto the toppe of the ground, from whence it riseth a little bigger naked or bare of leaves for an inch or two, and then sendeth forth from the sides of the same stalke, sundry small stalkes of very fine cut leaves, little bigger than haires, of a sad greene colour, and at the toppe whereof sundry branches of white flowers in umbells, and such like small long seede, as in the former, but lesser, ond somewhat sharpe in taste.

The Place and *Time.*

The first is as frequent in the upper and lower *Germany*, and in *France* and *Italy*, and the lesser more frequent in our country than theirs, although, as *Camerarius* saith, it groweth by the *Rheyne* also, and flower in the beginning of Summer, seeding quickly after.

The

The Names.

It hath no Greeke name, but what is acquired from the Latine, which is ἀγειοκάστανον, when as the Latines by a corrupt word doe call it *Bolbocaſtanum*, or *Bulbocaſtainum*, but by a better *Nucula terreſtris*, as *Lobel* doth, but *Guinterius* & *Goupilas* thinke that the word ſhould be rather *Balanocaſtanon*, which is as ſtrange as the other, and but formed together to ſhape it a coat ſutable to the wearing: *Dodonæus* in his former workes tooke it to be *Bunium* of *Dioſcorides*; but it ſeemeth upon better advice, he changed his opinion, and maketh no mention thereof in his later, or *Pemptades*: which *Lobel* alſo ſeemeth to ſtumble at, not knowing, as he ſaith in *Adverſaria*, *fol.* 71. any other plant that may repreſent *Dioſcorides* his *Bunium* if this be not it: but the deſcription of *Bunium* in *Dioſcorides* doth ſo much vary from this, and hath ſo little reſemblance, that I wonder judicious and learned men ſhould ſo erre, for if one or two words herein doe correſpond unto the *Bulbocaſtanum*, all the reſt contrarieth it quite, for beſides that *Dioſcorides* maketh no mention of the roote to be bulbous, or otherwiſe, which was not fit to be omitted, and giveth an eſpeciall knowledge of the plant; there is in this Earth-nut no ſquare ſtalke, nor of a fingers thickneſſe, nor in the true coppies, as *Lugdunenſis* noteth, is there any mention of Parſley-like leaves neare the rootes, but on the ſtalkes, nor are the flowers like Dill, which are yellow, nor is the ſeede ſmaller than Henbane, the properties alſo of each, being different, Thus have I ſhewed you that *Bolbcaſtanon* connot be *Bunium*, but what *Bunium* is, by the judgement of *Dalechampius*, I ſhall ſhew you a little hereafter among the wild Carrots. *Matthiolus* maketh the firſt here, to be his firſt *Oenanthe* in *fol.* 627. of *Bauhinus* edition; Doctor *Turner* tooke it to be *Apios*; and *Ceſalpinus* calleth it *Pancaſeolus*, and as *Camerarius* ſaith, *Geranium primũ Dioſcoridis*, but he ſaith that the *Italians* call it ſo; becauſe the vulgar eate it in ſtead of bread and cheeſe. *Lugdunenſis* calleth it *Bulbocaſtanon grandius*, as *Camerarios in horto* alſo aknowledgeth it, and doth call it *Bulbo caſtanum Tralliani*, but *Lugdunenſis* by that name underſtandeth the leſſer ſort calling it *mas*, becauſe he would make *afœmina*, which is a quite differing plant from this, as I ſhall ſhew you among the *Oenanthes*. *Geſner*, *Dodonæus*, *Tabermontanus* and others, doe generally call it *Bulbocaſtanum*. The other is, as I ſaid even now, called by *Lugdunenſis* *Bulbocaſtanum mas Tralliani*, and *Bulbocaſtanum alterum minoribus foliis & bulbis* by *Camerarius*, *Lonicerus* underſtandeth this plant, which he calleth a ſpecies of *Ornithogalum*. The *French Savoyards* call it *Faverottes*, the *Germans Erdkerſten*, and *Erdnuſſ*, the *Dutch Erdtnoten*, and wee Earth-nuts, Earth Cheſnuts, Gronnd nuts, and Kipper nuts.

Nucula terreſtris major vel minor.
Earth-nuts or Cheſnuts.

The Vertues.

The rootē is hot and drie, and ſomēwhat binding, yet all moderatēly, but the ſeede is morē in both, yet hath an opening propertie to provoke urine: the roote is ſaid to be good for thoſe that either ſpit or piſſe bloud: they that uſe to eate of them doe finde them nouriſhing as Cheſnuts, and no otherwiſe profitable in any eſpeciall reſpect.

CHAP. XII.

Oenanthe recepta herbariorum. Dropwort.

ALthough I know that none of theſe plants deſcribed in this Chapter, is the right *Oenanthe* of *Dioſcorides*, yet becauſe the common vote of theſe times paſſeth ſo upon them, and that I could not ſo well joyne them to the *Filipendulas* here before ſet forth, unto whom they are in ſome ſort like in that they were *umbellifers*, let me place them here to beginne this ſecond diviſion of the umbelliferous plants, which are of ſuch as beare thinne cut leaves, like Carrots or Parſley, and that in the laſt Chapter it was ſhewed you, that ſome did call the *Nucula terreſtris*, *Oenanthe*, as well as the ordinary *Filipendula*.

1. *Oenanthe Apij folio major.* The moſt ordinary great Droppewort.

This great Dropwort, hath for rootes, many round white and ſomewhat long Aſphodill like clogs, joyned together at the toppes, and ending in ſmall fibres, from whence riſe many greene winged leaves, made of many parts, cut in to the forme almoſt of Smallage leaves, but much ſmaller, and from among them two or three ſtiffe round ſtalkes, halfe a yard, or ſometimes two foote high, beſet with ſome ſuch leaves as grow below, and at the toppes ſundry ſpokes or umbells of white flowers, converted afterwardes into Fennell-like ſeede, but ſmaller, and of a darke whitiſh colour.

2. *Oenanthe Apij folio minor duarum ſpecierum.* Two ſmaller ſorts of the former Droppewort.

Theſe two ſorts of ſmall Dropworts have their winged leaves very like in the diviſions unto the former, but both

3. *Oenanthe Cretica ſtellata.*
Candy Dropwort with ſtarre-like heads.

5. *Oenanthe anguſtifolia Lobelij.*
Lobels narrow leafed Enanthe or Droppewort.

ſmaller by much & more green, yet the one of them alſo ſmaller than the other, and the leſſer a little finer jagged, which plainely ſheweth the difference as well as the ſeede, which is ſmaller almoſt by the halfe, and rounder than the greater of theſe, which is ſomewhat like unto Dill ſeede, but ſomewhat ſmaller and white, the flowers in either being white, but differing in greatneſſe: the rootes likewiſe are much alike; yet ſtill greater or leſſer the one than the othrr, and each conſiſting of ſundry ſmall tubers, with many ſtrings or fibres among them.

3 *Oenanthe Cretica ſtellata.*

Candy Droppewort with ſtarre-like heads.

After many yeares ſtanding, this ſendeth forth an upright ſtalke, ſcarce a foote high, without any leafe thereon, and with foure and five heads or tufts of white flowers, upon long foote ſtalkes, encompaſſed with eight or tenne ſomewhat long and pointed leaves like a ſtarre, after which follow ſmall ſeede ſomewhat like to the *Indian* Scabious: the leaves that grow below are winged, that is many ſmall ones ſet at diſtances upon a long foote ſtalke, very like, both for forme and bigneſſe, unto the biger of the laſt two recited ſorts which fall away in the Winter, and ſpringing a freſh in the Spring from the roote, which conſiſteth of ſundry Aſphodill like clogs, but leſſer, ſomewhat hard and blackiſh.

4. *Oenanthe Cretica prolifera.*

Candy Dropworte with fruitfull heads.

Very like unto the laſt is this Candiot, yet differing firſt in the leaves, which are larger and not cut into ſo many parts, then in the heads of flowers, which though white and cluſtering together like it, yet in ſtead of the long pointed leaves ſet thereabouts, this hath ſundry ſmall heads of the like white flowers, after the manner that many other plants have, namely Marigolds, Dayſies, &c. which we call childing or fruitfull, or as ſome doe, Iacke-Anapes a horſe backe, and againe in the ſeede, which is like to the water or Marſh kinde, and laſtly, and moſt eſpecially in the rootes, which are not glandulous like the other, but wholely compoſed of a number of white fibres

6. *Oenanthe Cicutæ facie Lobelij.*
Lobels Hemlocke-like Enanthe or Dropwort.

and

and threds: this alſo upon the firſt ſpringing thereof from the ſeede hath but three leaves upon divers ſtalkes, and thoſe after gaine more.

5. *Oenanthe anguſtifolia Lobelij.* *Lobels* narrow leafed Enanthe or Dropwort.

This Enanthe of *Lobel* is ſayd to be like the firſt, but with much narrower and finer cut leaves, and not to differ greatly in any other particular.

6. *Oenanthe Cicutæ facie Lobelij.* *Lobels* Hemlocke like Enanthe or Dropwort.

The leaves hereof are more like the medow Rue then Smallage having many ſmall ones ſet together of a fowle darke greene colour, and ſomewhat like Hemlocke in colour as alſo in the flowers but more in effect, troubling and overturning the braine and ſenſes being eaten as *Lobel* ſaith, the rootes are white and glandulous, or Aſphodill like ſoft and tender but ſharpe and unpleaſant in taſte, yeelding a whitiſh milke at the firſt, and turning yellow after, which is poiſonous, virulent and exulcerating.

7. *Oenanthe paluſtris ſive aquatica.* Marſh Dropwort.

The lower leaves hereof are much divided into many ſmaller parts then the former ſorts, but thoſe that grow upon the hollow ſtalkes are much finer and ſmaller: the ſpikie umbells of flowers are white as the other, and the ſeede like Hemlocke: the rootes are many ſmall tubers faſtned by ſtrings and other fibres among them.

8. *Oenanthe Monſpeliaca major & minor.* French Dropwort a greater and a ſmaller.

The greater of theſe two French plants of *Dalechampius* as *Lugdunenſis* remembreth them, hath a thicke creſted ſtalke about a foote high and leaves thereon like unto Carrots, the umbells of flowers are white, and ſomewhat long ſeede ſucceeding: the rootes have many ſomewhat long and blackiſh tubers with other fibres among: The leſſer ſort hath a thicke handhigh ſtalke, and the like Carrot-like leaves: but the ſeede thereof is flat like *Arrache*, wherein hee ſaith, as alſo in that it groweth in ſtony places, it commeth nearer then the other unto the right *Oenanthe* of *Dioſcorides* although the other in all other things is neareſt thereunto: the rootes hereof alſo are ſmall and tuberous like the other.

9. *Oenanthe Iuncoides minima.* Small Ruſhlike Enanthe or Dropwort.

Although I here give you the leſſer figure of *Lobels Oenanthe aquatica* in want of the right, whereunto this doth come very neare, yet the deſcription ſhall amende that defect: For it hath ſundry very fine and ſmall divided greene leaves lying on the ground all the Winter and ſome as ſmall and fine as *Meum Spignell*: but thoſe upon the hollow greene Ruſh-like ſtalkes which are about halfe a yard high are finer by much, yet very few, and at the upper joynt with the leafe and not at the top of the ſtalke come forth a few very ſmall white flowers which turne into very ſmall ſeede: the heads or tubers that bee diſperſed among the ſmall haire like fibres, are as ſmall as reaſonable big Pins heads, which abide and periſh not encreaſing yearely, but beſt in a moiſt and ſhadowie place.

10. *Oenanthe tenuifolia altera Africana.* Fine ſmall Dropwort of *Africa*.

I have yet one other of theſe *Oenanthes* to ſhew you which *Boel* gathered on the *Barbary* coaſts and brought to us, having a ſmall ſlender broad ſtalke with very fine cut leaves thereon as fine as either Dill or Spignell, ſet at diſtances with divers branches of umbel-like white flowers at the toppes, changing into very fine white ſeede: the roote being ſmall and tuberous like the laſt.

The Place and *Time:*

All ſave the ſecond two ſorts, and thoſe particularly entituled grow in our owne Land, which ſecond and laſt have not beene remembred by any other before, flowring and ſeeding in the end of Summer.

The Names.

Dioſcorides hath by *Matthiolus* judgement recorded three ſorts of οἰνάνθη *Oenanthe*, derived ἀπὸ τῆς οἴνης & ἄνθος *a vino & flore quaſi flos vinoſus, quod florum decore, odore et quadantenus colore non ſint viti diſſimiles: vel etiam Leucanthon appellari a florum candore ſcribit*, yet *Theophraſtus* in the laſt Chapter of his ſixt Booke maketh mention but of one ſort not to be excluded from the number of flowers yet ſowen of ſeede, which all doe interpret to be the bloomings of the wild Vine, and as *Matthiolus* ſaith *Dioſcorides* implyeth that wild Vine that beareth Grapes as well as that which is barren. Divers authors have diverſly judged of *Dioſcorides* his *Oenanthe*, *Matthiolus* contradicting *Fuchſius*, who firſt and *Lobel* after him that ſtrove to maintaine his opinion, that the common *Filupendula* was it: yet notwithſtanding *Lobel* his opinion, *Matthiolus* his reaſons ſtand for good arguments thereagainſt. And although as I ſayd in the beginning of this Chapter, I here ſhew you many diverſities of *Oenanthe* as they are ſo accounted, yet we cannot be aſſured that any one is the genuine and right plant: and howſoever as you heare *Fuchſius* and *Lobel* would maintaine *Filipendula*; *Lugdunenſis* his ſmaller *Mompelier Oenanthe*, *Alpinus* alſo as much inſiſteth that his is the right, yet ſtill there is ſomewhat defective in each of all theſe, namely eyther in the rootes or ſtalkes, or ſeedes: but becauſe I cannot abſolutely determine this controverſie, I muſt leave every one to his owne judgement, touſe them that are found moſt vertuous. For the names, the firſt doe moſt truly deſerve the name of *Apij folio*, which our countrey women herbe gatherers, and ſellers moſt falſly call white Peony rootes, becauſe the rootes are white and cloggy, ſomewhat like unto the female Peony rootes: the reſt have names according to the titles their authors give them, yet except the firſt, the third and the ſixt they have all roots more like unto *Filipendula*: *Bauhinus* in my opinion hath much miſtaken himſelfe in quoting *Columna* his *Cyminum bulboſum Plinij* to bee *Oenanthe Apij folio* which may plainely bee ſeene to bee the *Nucula terreſtris* or *Bulbo caſtanum* which is *Matthiolus* his firſt *Oenanthe* after *Filipendula*, and not *Oenanthe Apij folio* which is his ſecond.

The Vertues.

Lobel onely brandeth his *Oenanthe Cicutæ facie* to be virulent and venemous, from the relations of the North country people, whereas he ſaith it chiefely groweth, and conteſteth againſt *Matthiolus* that approved it beneficiall in Hiſtericall, Epileptical, Analeptical and Cephalicall diſeaſes, as alſo the Strangury or hard making of water; yet holdeth the other to be by ſome ſingular prerogative available in the ſame caſes. *Alpinus* alſo commendeth his *Candy Oenanthe Stellata* to be good for them that have the ſtrangurie.

CHAP. XIII.

Daucus. Dauke or wilde Carrots.

ALthough there be many ſorts of theſe Daukes or wilde Carrots, yet becauſe I cannot well tell how to ſeperate them, I muſt packe them all into this one Chapter.

1. *Daucus Creticus verus Dioſcoridis.* The true Dauke of *Candy*.

The true *Candy* Dauke hath ſundry ſtalkes of winged leaves, as finely cut as Fennell but ſhorter, ſet at diſtances one againſt another, of a whitiſh or hoary colour ſmelling ſomewhat ſweete, from among which riſe divers ſlender branched ſtalkes a foote high, bearing at their tops ſmall umbells of white flowers, and after them ſmall hoary grayiſh ſeede, ſomewhat long and round of a quicke ſent and taſte: the roote is ſmall, long and white, almoſt as quicke and ſharpe both in ſent and taſte as the ſeede, but will not abide our Winters with all the care we can uſe.

2. *Daucus Alpinus Cretico ſimilis.* Mountaine leafed Dauke.

This fine Dauke differeth little from the former which is in that it groweth in colder places, the leaves being ſomewhat longer and greener then the former, nothing ſo hoary or white, and grow not ſo many or thicke together. the umbells of flowers are white and the ſeede like alſo, but a little longer and not ſo hoary, but ſomewhat neare both in taſte and ſmell: the roote alſo is quicke and ſharpe as the other.

3. *Daucus montanus Pannonicus.* Mountaine Dauke of *Hungary*.

This Dauke of *Hungary* which *Cluſius* calleth *Saxifraga Pannonica*, and *Bauhinus Daucus montanus multifido brevique folio*, hath ſundry long ſtalkes of fine cut leaves and ſhort, ſomewhat like unto the leaves of Fumitery, of a ſtrong ſent and taſte, and ſomewhat ſharpe withall; among which riſe up joynted ſtalkes about a foote high with the like leaves on them, and at their tops umbells of white flowers: the roote is but ſhort and blackiſh taſting quicke and ſharpe, drawing water into the mouth upon the chewing, and hath a buſh of haires at the toppe.

4. *Daucus montanus pumilus.* Low or dwarfe mountaine Dauke.

This Dwarfe kind hath a few ſmall ſtalkes with fine cut leaves longer then the laſt, and but thinly or ſparingly ſet thereon, ſomewhat reſembling Sow-Fennell but ſeldome exceeding fifteene leaves on a ſtalke: from among which leaves riſeth up a ſhort thicke ſtalke not a foote high, branched from the bottome upwards with the like leaves on them, but ſeldome exceeding nine on the ſtalke, broadeſt below and of the ſmell and taſte of Carrots; the toppe of each branch and ſtalke is furniſhed with many ſmall umbells of white flowers without any ſent at all, unto which ſucceede ſmall ſeede like Parſley: the roote is ſmall and ſhort, browne and rugged on the outſide, and white and ſpongie within having a buſh of haires at the head: *Cluſius* calleth this *Selinum montanum pumilum*, but *Bauhinus* referreth it to the wilde Carrots and calleth it *Daucus montanus multifido folio Selini ſemine.*

1. *Daucus Creticus verus Dioſcoridis.*
The true Dauke of *Candy*.

2. *Daucus Alpinus Cretico ſimilis.*
Mountaine fine leafed Dauke.

3. *Daucus montanus Pannonicus.*
Mountaine Dauke of *Hungary.*

4. *Daucus montanus pumilus.*
Low or dwarfe mountaine Dauke.

7. *Daucus tertius Dioscoridis Bello.*
Coriander leafed Dauke.

5. *Daucus Selinoides major.*
The greater Parsley leafed Dauke.

5. *Daucus Selinoides major.* The greater Parſley leafed Dauke.

The greater of theſe Daukes which hath large ſtalks of ſomewhat broad pale greene leaves bigger then Parſley, and with diviſions of the ſame faſhion and manner next the ground, hath ſomewhat bigge ſtalkes almoſt two foote high with the like leaves at the joynts but ſhorter, and at the toppes ſpokie rundles of white flowers which turne into long creſted ſeede bigger then ordinary Fennell ſeede, and of a yellow browne colour: the roote is ſomewhat great, thicke, long and white, with a buſh of haires at the head as many other umbelliferous plants have, and of a hot and ſharpe taſte as the ſeede is alſo. There is another ſort hereof as *Lobel* in his obſervations
Minor. ſaith, ſomewhat leſſe then the former but elſe agreeing therewith in all parts, which hee found in the wood by *Narveum*.

6. *Daucus Selinoides maximus.* The greateſt Parſley leafed Dauke.

This greateſt kinde called by *Cluſius Seſeli alterum Pannonicum* yet putteth the figure of the laſt for it, hath a roote ſometimes as great as ones arme, or being young of the bigneſſe of ones thumbe, parted into ſeverall branches at the bottome, and covered with a rugged blacke barke of a clammy taſte at the firſt, but ſharpe afterwards and cauſing ſpitting, having at the toppe many hairy heads, from whence ſpring ſundry very large and great winged leaves, much divided and dented about the edges ſomewhat like the laſt but larger, of a faint greene colour ſomewhat ſhining on the upper ſide, and of a grayiſh aſhcolour underneath: among which riſeth up a large great creſted ſtalke of a fingers thickneſſe, with ſome joynts and leaves at them, and with branches alſo from betweene them, at the tops whereof ſtand ſmall umbells of whitiſh flowers, and ſomewhat larger but like ſeede as the laſt. Both theſe two laſt ſorts may well be referred to the ſecond *Daucus* of *Dioſcorides*, whoſe leaves are like *Selinum* or Parſley before any other.

7. *Daucus tertius Dioſcoridis Bello.* Coriander leafed Dauke.

This Dauke which *Honorius Bellus* ſaith groweth in *Candy*, and is referred by him to the third *Daucus* of *Dioſcorides*, and both leafe and roote eaten by the *Candiots* as a familiar Sallet herbe, hath ſundry ſtalkes of fine cut leaves ſomewhat like to *Corianders* but leſſer and thicker, the ſtalkes are neare two foote high, with great and ſwollen joynts (and therefore called by ſome *Seſeli nodoſum*, but by *Bauhinus Daucus Creticus nodoſus umbella lutea*) and ſmaller leaves at them, at the tops whereof grow yellow umbells of flowers but white with me, which turne into bigger ſeede then Fennell: the roote is great, thicke and ſhort, periſhing yearely, the whole being aromaticall.

8. *Daucus montanus Apij folio flore luteo.* Mountaine Dauke with yellow flowers.

This yellow flowred Dauke hath a creſted ſmooth ſtalke branching forth into ſundry parts, having leaves like unto Smalage but ſhorter and not dented at all about the edges, ſet on both ſides of the creſted ribbe, the flowers are ſmall that grow at the toppes and yellow.

9. *Daucus pratenſis Apij folio Bauhini.* Medow Dauke of *Bauhinus*.

The rootes of this Dauke are long and reddiſh on the outſide ſmelling and taſting like Carrots, being hairy at

8. *Daucus montanus Apij folio minor.*
Mountaine Dauke with yellow flowers.

11. *Daucus ſecundus Dalechampij.*
The French wilde or fielde Dauke.

the

at the toppe, from whence riſe ſtalkes with many winged leaves on both ſides, cut in on the edges and dented alſo round about, ſomewhat like unto the laſt, but much ſmaller and of a pale greene colour, betweene which riſeth a ſlender ſtraked ſtalke a foot high or ſeldome higher, with few joynts and leaves, parted into ſome branches with umbells of white flowers at the toppes of them, which turne into blackiſh long ſeede ſmelling well.

10. *Daucus Hiſpanicus.* *Spaniſh* Dauke.

The *Spaniſh* Duake hath a thicke long roote, parted into thicke long ſtrings hairy at the head, from whence riſe great winged ſtalkes of leaves, parted into divers other winged or divided leaves ſet one againſt another on a middle ribbe, of a ſullen greene colour, among which riſeth one or two ſtalkes as high as a man being ſomewhat reddiſh, creſted and joynted with the like leaves at them, but leſſer branching forth diverſly, and bearing large umbells of yellowiſh flowers, after which come flat and ſomewhat thinne round ſeede. This came to me by the name of *Daucus Hiſpanicus*, but doth very well anſwer the *Daucus Alſaticus* of *Bauhinus* in his *Prodromus* in every part which hee ſaith doth well agree unto the *Apium paluſtre* of *Dodonæus*, and to the *Thyſſelinon Plinij* of *Lobel*, but that it giveth milke which this doth not and that this riſeth much higher then that: the ſmell and taſte of this is wholly like unto a Carrot.

11. *Daucus ſecundus Dalechampij.*
The French wilde or fielde Dauke.

This kinde of field Dauke hath a long round white root, like unto a ſmall long Carrot, ſweet and ſomewhat ſharpe, hairy at the head, with long ſlender ſtalkes of winged leaves riſing from it, which are whole and ſomewhat thicke, not gaſhed or cut in on the edges but dented, reſembling Parſnep leaves but much ſmaller, ſeaven for the moſt part ſet together one againſt another ſomewhat cloſe, and the odde one at the end, the ſtalke is a cubit high or higher, with finer leaves at the joynts then grow below

12. *Daucus tertius Dalechampij.*
Another French wilde Dauke.

15. *Daucus ſtellatus.* Starre headed Dauke.

16. *Daucus Alſaticus.* Dauke of *Germany.*

with ſtore of white flowers in umbells, and ſmall long ſeede after them, ſomewhat ſweete in ſmell and ſharpe in taſte.

12. *Daucus tertius Dalechampij.* Another French wilde Dauke.

This other French wild Dauke hath a whitiſh yellow roote ſhort and ſlender with haires at the head: the ſtalkes of leaves that grow next thereunto are ſomewhat broad like unto the lower leaves of Corianders, but thoſe grow higher on the ſtalkes are ſmaller and ſmaller, being as ſmall as Fennell at the higheſt, the flowers are white and the ſeede ſomewhat long like in taſte unto Dill or Cumin that is ſharpe.

13. *Daucus pratenſis Dalechampij.* Wilde Dauke with water Milfoile leaves.

This fine leafed Dauke hath divers long ſtalkes of moſt fine leaves ſet many together at ſpaces one againſt another, very like unto the water Yarrow or Milfoile, being ſoft and of a freſh greene colour: the ſtalke hath ſome few joynts and fine long leaves like Fennell ſet at them with branches riſing from thence, likewiſe bearing large umbells of flowers which are reddiſh at the beginning and white when they are open, ſomewhat bitter and ſharpe but well ſmelling.

14. *Daucus Petroſelini vel Coriandri folio ſive Bunium Dalechampij.* Rockie wilde Dauke.

The wilde Dauke that groweth in rough and rockie or ſtony places riſeth up from a ſmall white branched well ſmelling roote, hairy at the head with ſundry long ſtalkes of leaves ſo nearely reſembling Parſley that many are deceived at the firſt ſight untill they better heede it, the ſtalke is ſquare, tall and of a fingers thickneſſe, with finer leaves thereon like the finer leaves of Corianders and umbells of flowers like Dill, the ſeede is ſmaller then Henbane ſeede of a good ſent.

15. *Daucus ſtellatus.* Starre headed Dauke.

This Dauke hath ſundry leaves, at the ground are ſomewhat like unto Parſley, but ſmelling well like the *Candy* Dauke and taſting hot: the ſtalke hath ſundry branches ſet with the like leaves at them, and yellow umbells of flowers which are ſucceeded by ſmall ſeede veſſells, having five ſmall leaves like thornes under them, repreſenting little ſtarres five or ſix ſmall threds riſing from the bottome to the toppes making every head ſeeme like a Cone, each ſtanding ſeparate by it ſelfe on its owne footſtalke, ſmelling ſweet and aromaticall in taſte: the roote is thicke and long like unto a Parſley or Parſnep roote, and eaten familiarly by the Natives either raw or boyled, and held good to procure Vrine, womens courſes and Venery.

16. *Daucus Alſaticus.* Dauke of *Germany.*

This *Germane* Dauke hath a thicke root ſomewhat long, with ſundry great ſtrings thereat, and at the head many haires from whence come divers large winged leaves made of many parts, ſet one againſt another, among whom one or two reddiſh ſtalkes, ſeldome more doe riſe to a mans height, divided into many branches and they into leſſer with the like but ſmaller leaves at the joynts, and at the toppes ſtand large umbells of yellowiſh flowers and ſomewhat flat ſeede ſucceeding them.

The Place and Time.

The two firſt ſorts grow not onely in *Candy* but in many places and countries, the ſhorter, thicker ſet and more hoary leaves in the warmer, and the longer, thinner ſet and leſſe hoary in the colder countries of *Germany*, *Swiſſerland* and *Savoy*; moſt of the reſt are declared in their titles or deſcriptions: many of them flower and ſeede ſomewhat earlier then others, yet all before the end of Autumne.

The Names.

The Greekes call it Δαῦκος, and the Latines alſo *Daucus*, *Daucum* and *Daucium*. *Dioſcorides* made three ſorts thereof, the firſt he named *Creticus* the ſecond *Selinoides* that is with leaves like Parſley, and the third with leaves like *Coriander*, which ſeverall ſorts hath cauſed many learned men to ſuppoſe divers herbes to be the ſame which are ſince found much differing, and yet the certainetie of the two laſt is not fully aſſured, but that ſome doe juſtly queſtion thoſe are held to be the trueſt. For as for the firſt it is in theſe times, and ſo hath beene for a good while in *Italy*, *France*, *Germany*, &c. well knowne and onely uſed now a dayes in all the compoſitions wherein *Daucus* is appointed to be put: whereas formerly the common wilde Carrot (which is in moſt things like the manured, except the roote which is more hard and wooddy, and more phyſicall and not edible as it is) was wholly uſed of all inſtead of the true *Candy* kinde: but to come to the declaration of theſe here ſet downe. The firſt is now well knowne to be the true *Daucus Creticus* of *Dioſcorides*, as *Lobel*, *Matthiolus*, *Geſner* and others have obſerved it and ſo ſet it downe: the ſecond alſo is acknowledged to be ſo like the firſt, that the climate and country onely maketh the difference as I ſayd before, and ſo ſay *Geſner*, *Camerarius*, *Lobel* and others: the third and fourth I have ſhewed in their deſcriptions to whom they belong and how they called them: the fift is diverſly named, for *Tragus* and *Matthiolus* call it *Dioſcorides* his ſecond *Daucus*, and *Dodonæus* the other kinde of *Libanotis* of *Dioſcorides* and *Theophraſtus*, *Camerarius*, *Geſner* and *Fuchſius* to be *Seſeli Peloponenſe*, *Lobel* ſaith it is *Saxifragia Venetorum*, and *Cluſius* as I ſayd giveth the figure of this for his *Seſeli montanum alterum*, whoſe deſcription doth expreſſe the next or ſixt here ſet downe, which *Bauhinus* in his *Pinax* entituleth *Daucus montanus apij folio albicans*, but I have for the neare reſemblance unto the former *Selinoides* called it *maximus*, becauſe it is greater then it: the ſeventh is expreſt to be from *Honorius Bellus* of *Candy*, as it is ſet downe in his firſt Epiſtle to *Cluſius*, and by *Pona* in his *Italian Baldus* in the ſame words: the eighth and ninth are remembed onely by *Bauhinus* in his *Pinax* and deſcribed in his *Prodromus*, the foure next unto them are expreſſed in their titles or deſcriptions as much as is fit for them: the foureteenth is as I ſayd in the title called *Bunium Dalechampij* by *Lugdunenſis*, which *Bauhinus* calleth as it is in the title alſo *Daucus petroſelini vel coriandri folio*: but concerning this *Bunium* I muſt ſay ſomething thereof here as I promiſed before in the Chapter of *Bulbo caſtanum*, that is to ſhew you that this *Bunium Dalechampij* is referred by *Bauhinus* to the kindes of *Daucus*, the deſcription and figure thereof are both ſo anſwerable thereunto: but yet I muſt withall give you my opinion thereof which is, that I thinke this herbe is rather forced then yelding freely of it ſelfe to take upon it this title, the compoſure of the deſcription being ſo punctually applyed to every part of *Dioſcorides* his deſcription moving that doubt in me: yet I would bee loth to derogate eyther from the accurate judgement or ſinceritie of ſo learned an Herbariſt as *Dalechampius* was. The *Arabians* call it *Dauco* and *Giezar*, the *Italians* and all other nations doe for the moſt part follow the Latine as neare as their Dialect will permit, or elſe following the *French Carot Savage* as ſome doe with us, to call them wilde Carots, or rather as is more fit Dauke according to the Latine, becauſe there is another herbe more properly called wilde Carrot.

The

The Vertues.

Although the herbe of thē truē Daukē is by the watery moiſture therein leſſe effectuall then the ſeede, as *Galen* ſaith, which hath that powerfull heate therein that it is a principall medicine to helpe the ſtrangurie, to provoke urine and womens courſes, to expell thē dead birth and helpe the ſuffocation of the mother, yet the herbe is of a temperate qualitie, and will helpe to digeſt humors by exhaling them by the pores, if it bee applyed thereunto yet leſſe then the ſeedes, which is powerfull to diſcuſſe griping paines, torments and wounds in the body or bowells, and eſpecially profitable for thoſe that are bitten by the *Phalangium* or deadly Spider, and the rootes as well as it effectuall againſt any other venemous beaſt, or any other venom, or poyſon or peſtilence being drunkē with wine: the ſame alſo put into pulteſſes doth eaſe tumors and ſwellings in any part, being mixed with hony it helpeth old and inveterate Coughes.

CHAP. XIIII.

Paſtinaca tenuifolia. Carrots.

HAving ſhewēd you in the laſt Chaptēr all the ſorts of *Daucus* which ſome for want of a more proper name have called wilde Carrots, I will in this ſhew you all the reſt whether tame or wilde that ſo they may ſtand together.

1. *Paſtinaca tenuifolia ſativa lutea.* Common yellow Carrots.

The common Carrots I might well have ſpared to deſcribe here, having ſhewed you all thē ſorts of them in my former booke, but ſeeing I am to ſpeake of ſome wilde ſorts which are like unto the manured, it ſhall not be impertinent to ſet them forth againe that ſo the wilde ſort may bee knowne wherein they differ. This is well knowne to have divers large ſpread leaves made of many thin cut deepe greene leaves divided into many parts, among which riſeth a round ſtalke three or foure foote high bearing large tufts of umbells of white flowers which doe cloſe together and ſpread not much, and turne into ſmall whitiſh rough or hairy ſeede holding one to another, the roote is ſomewhat great and yellow, big above and ſmall pointed below, without any fangs or twines of a pleaſant ſweete taſte, and therefore wholly ſpent for foode. There are other ſorts as I have ſhewed in my former booke, whereunto I referre them that are deſirous to know, but I have ſeene this garden yellow kinde by ſowing it ſelfe ſometimes the root to become white.

2. *Paſtinaca tenuifolia ſylveſtris.* Wilde Carrots.

The wild groweth in a manner altogether like the tame but that the leaves are ſomewhat whiter and rougher & ſo are the ſtalkes likewiſe which beare large ſpokie tufts of white flowers, with a deepe purple ſpot in the middle which are contracted together when the ſeede beginneth to ripen that thē middle part being hollow and low, and the outer ſtalkes riſing high maketh the whole umbell ſhew like unto a birds neſt, as I ſhewed before in the Chapter of ſtrange Chervills the *Gingidium verum* uſeth to doe, the roote is ſmall long and hard, unfit for meate, being ſomewhat ſharpe and ſtrong, although *Dioſcorides* ſeemeth to ſay it was uſed to be be eaten.

Paſtinaca ſativa altera tenuifolia atrorubens.
Common red Carrots.

3. *Paſtinaca ſylveſtris Apula Columnæ.*
Wilde Carrots of *Naples.*

This Neapolitane Carrot is ſo like in leaves and ſtalkes unto the laſt that they can hardly be diſtinguiſhed one from the other before it be in flower or ſeede, for although the whole winged leafe ſeemeth to be leſſe and the parts fewer, yet therein is ſmall or no difference: but being in flower the umbells are larger, the flowers darke purple, with a reddiſh yellow ſpot in the middle, and the ſeede (wherein lyeth the chiefeſt difference) long and ſmall, with a little white hairineſſe upon them, and not rough as Carrots, being more like to the true *Daucus*, but of a reddiſh colour being greene and freſh, and of a bitter and little aromaticke taſte: the roote is ſomewhat long, white, hard, ſweet and aromaticall.

4. *Paſtinaca echinophora Apula.*
Prickly wilde Carrots of *Naples.*

The roote of this kinde of Parſnep or white Carrot is of a fingers thickneſſe and a cubits length, equall alike, like unto *Eryngium* or the Sea Holly roote, ſomewhat yellow on the outſide and white within, the barke being thicke and of ſubſtance, with a ſmall pith of a taſte ſomewhat ſharpe and ſweetiſh bitter, not unpleaſant, eſpecially the younger rootes, thē leaves that lye upon the ground are like unto thoſe of ordinary Carrots, yet not altogether ſo large and broad, but are finely cut and as it were betweene it and the Sea kinde, of a whitiſh greene colour with ſome hairineſſe: the ſtalke is thicke and full of branches and leaves which bend a little downewards and make them globe faſhion, being ſmaller, leſſe divided, harder and rougher thereon up to the toppes, where the umbells of yellow flowers ſtand, which have ſix thicke ſharpe pointed ſmall leaves at the bottome of them, the middle umbell firſt

1. *Pastinaca tenuifolia sativa lutea.* Common yellow Carrots.

2. *Pastinaca tenuifolio sylvestris.* Wilde Carrots.

flowring, and the reſt at the ſides afterwards: after they are paſte the ſeede appeareth which is of an ovall forme, long and round, hard and ſtraked, with ſix lines pointed at the toppes and yellowiſh, whoſe inner kernell is browniſh, and of an aromaticall ſavour. This ſaith *Columna* differeth from the uſuall *Paſtinaca marina* both in the large ſpreading and manifold fine diviſions of the leaves, and in the pleaſanter taſte and greatneſſe of the roote, reſembling rather a Parſnep although their ſeedes are alike.

5. *Paſtinaca ſylveſtris hirſuto caule.* Wilde Carrots with hairy ſtalkes.

The roote of this Carrot is white and often a foot long, ſometimes ſingle and ſometimes divided into two or three parts, very like both in ſent and taſte to a Parſley roote, but hotter in the mouth for a long time, from whence riſeth up a ſtalke a foote and a halfe high as thicke as ones little finger at the bottome, being ſomewhat round but creſted or cornered very plainly, exceeding hairy and full of joynts, whereat grow large creſted ſtalkes of winged leaves compaſſing the ſtalke at the bottome, a foote in length, divided into ſundry leaves, and they againe into other ſmaller parts very rough and hairy alſo, and of a yellowiſh greene colour, from betweene which leaves and the ſtalkes at the joynts, come forth other creſted ſtalkes and the like leaves at their joynts but leſſer, and doe very well reſemble the leaves of our garden Carrots but larger and ſoft if one handle them hard, but rough both on the backe and edge being gently touched: from every one almoſt of theſe joynts both of the ſtalke and branches ariſeth a certaine long huske, conſiſting of ſix ſmall long leaves cloſe ſet together which when it openeth ſheweth forth a ſmall tuft or cloſe umbell of white flowers, and ſometimes yellowiſh ſomewhat ſweet, after which doe follow ſomewhat round ſeede, two alwayes joyned together and very prickley, on the backſide, the inner ſide being flat and more yellow then Carrot ſeede, elſe ſomewhat like.

The Place and *Time*.

The firſt kindes are alwayes ſowen in Gardens or in the fields choſen out for that purpoſe, the reſt grow wilde: the firſt plentifully in our owne Land by the fields ſide and in untilled places: the laſt in the like places of *Germany*: the reſt in *Naples* and doe all flower and ſeede in the end of Summer.

The Names.

Σταφυλῖνος in Greeke derived (as is moſt likely) from σάφυς the grape when it is almoſt ripe whoſe purpliſh colour the one ſort hereof doth reſemble and not from σίφυλος, the ſtalke of Bryonie as ſome thinke doth anſwer both to the tame and wilde ſorts of *Paſtinaca* in Latine as *Dioſcorides* ſheweth in the ſaid Chapter, but uſually *Staphylinus* ſimply is taken for the wilde Carrot if ἄγριος be not joyned with it to expreſſe the tame but *Paſtinaca*, which in Latine ſeemeth to take the name *a paſcendo cum corpus alat*, is now a dayes divided into two ſorts that is into *latifolia* which is the Parſnep whereof I ſhall ſpeake hereafter, and into *tenuifolia* which is the Carrot called alſo *Carota* by divers from the *Italians* who doe ſo call it, but *Dodonæus* thinketh the word was deduced from the *Germans Garrot* which is *totum rubens* but I doe not ſo thinke, and *Daucus niger* as it is thought by *Theophraſtus*, whereof yet there is ſome doubt whether the word ſhould not be μηλίναν which is yellow, as it is in moſt true copies rather then μελαίναν which is blacke as it is but in few. *Galen* alſo ſeemeth to call it *Daucus*, but with

an
